During the joint lives of these two great poets, it appears that they wrote nothing separately, excepting one little piece each, which seemed of too trivial a nature for either to require assistance in, namely, *The Faithful Shepherd*, a pastoral, by Fletcher; and *The Masque of Gray's Inn Gentlemen*, by Beaumont. Yet what share each had in the writing or designing of the pieces composed by them jointly, there is no possibility of determining. It is however generally allowed that Fletcher's peculiar talent was wit, and Beaumont's, though much the younger man, judgment. Nay, so extraordinary was the latter property in Beaumont, that it is recorded of Ben Jonson, who seems to have been by no means wanting in a good opinion of his own abilities, that he constantly, during the lifetime of Beaumont, submitted his own writings to his censure, and, as is thought, availed himself of his judgment at least in the correction, if not even in the contrivance of all his plots. It is probable, therefore, that Beaumont's share of the work generally consisted in forming the plots and contriving the conduct of the fable, as well as writing the more serious and pathetic parts, and lopping off the redundant branches of Fletcher's wit, whose luxuriance, it is said, stood frequently in need of castigation. Fletcher, again, whose conversation with the fashionable world (to which indeed both of them from their birth and station in life had been ever accustomed), added to the volatile and lively turn he possessed, rendered him perfectly master of dialogue and polite language, probably executed the designs formed by the other, and raised the superstructure of those lively and spirited scenes of which Beaumont had only laid the foundation. In this he was so successful, that although his wit and raillery were extremely keen and poignant, yet they were at the same time so perfectly polished, that they used rather to please than disgust the very persons on whom they seemed to reflect. Yet that Fletcher was not entirely excluded from a share in the conduct of the drama, may be gathered from a story related by Winstanley, that the two bards having concerted the rough draught of a tragedy over a bottle of wine at a tavern, Fletcher said he would undertake to "kill the king;" which words being caught by the waiter, who had not overheard the context of their conversation, he lodged an information of treason against them. But on their explanation that it only meant the compassing the death of a theatrical monarch, and their loyalty being moreover unquestioned, the affair ended in a jest.

Beaune || Beauty.

The works of Beaumont and Fletcher, *par nobile fratrum*, possess great and enduring merit; and some of their dramas deservedly stand on the list of the stock pieces of the theatre. The plots are ingenious, interesting, and well managed; the characters are strongly marked; and the dialogue is sprightly and natural; yet there is in the latter a coarseness which is not suitable to the politeness of the present age, and a fondness for repartee, which frequently runs into obscenity, and which we may suppose to have been the vice of the time, since even Shakspeare himself is not entirely free from it. But as these authors have more of that kind of wit than the "Swan of Avon," it is not to be wondered if, in the licentious reign of Charles II., their works were preferred to his. Now, however, the tables are entirely turned; and while Shakspeare's immortal works form our constant and daily study, those of Beaumont and Fletcher are only occasionally dipped into. Some of their plays were printed in quarto during the lives of the authors; and in the year 1645 there was published in folio a collection of such of their plays as had not been printed before, amounting to between thirty and forty. This collection was published after the shutting up of the theatres, by Shirley, and dedicated to the Earl of Pembroke by ten of the most famous actors. In 1679 there was an edition of all their plays published in folio; and another appeared in 1711 by Mr Tonson, in seven volumes 8vo. The finest edition is that of Weber, in 14 vols. 8vo. Another edition, by Mr Dyce, in 11 vols. 8vo, is worthy of mention.

BEAUNE, an arrondissement of the department of Côte d'Or, in France, extending over 769 square miles, and comprehending 10 cantons and 201 communes. Population (1851) 124,206. The chief city, of the same name, is situated on the river Buozcoise, twenty-three miles S.S.W. of Dijon on the Paris and Lyons railway, in a district highly productive of the best Burgundy wine. Pop. (1851) 10,800.

Beaupréau || Beauty.

BEAUPRÉAU, an arrondissement in the department of the Maine and Loire, in France, extending over 629 square miles, and containing 7 cantons and 75 communes. Pop. 121,375. The chief town, of the same name, is on the river Evre, 27 miles S.W. of Angers. Pop. (1851) 3448.

BEAUSOBRE, Isaac de, a learned Protestant writer, of French origin, was born at Niort in 1659. He was forced into Holland to avoid the execution of a sentence which condemned him to make the *amende honorable* for having broken the royal signet, which was put upon the door of a church of the reformers to prevent the public profession of their religion. He went to Berlin in 1694, and was made chaplain to the king of Prussia, and counsellor of the royal consistory. He died in 1738, aged seventy-nine, after having published several works, among which may be mentioned, 1. Défense de la Doctrine des Réformés. 2. A Translation of the New Testament, with Notes, jointly with M. Lenfant; much esteemed among Protestants. 3. Dissertation sur les Adamites de Bohème; a curious work. 4. Histoire Critique de Manichée et du Manichéisme, 2 tom. 4to. This is a very learned and valuable work; discussing, as Gibbon observes, "many deep questions of Pagan and Christian theology, and forming a rich treasury of facts and opinions." 5. Several dissertations in the Bibliothèque Britannique. Beausobre had strong sense with profound erudition, and was one of the best writers of his time; and he preached as he wrote, with spirit and ability.

BEAUTY,

That property in objects by which they are recommended to the power or faculty of taste—the reverse of ugliness—the primary or more general object of love or admiration.

Necessary imperfection of the definition.

These, we confess, are rather explanations of the word than definitions of the thing it signifies; and can be of no value, even as explanations of the word, except only to those who understand, without explanation, all the other words they contain. For, if the curious inquirer should proceed to ask, "And what is the faculty or power of taste?" we do not see what other answer we could give, than that it was that of which beauty was the object, or by which we were enabled to discover and to relish what was beautiful. It is material, however, to observe, that if it could be made out, as some have alleged, that our perception of beauty was a simple sensation, like our perception of colour; and that taste was an original and distinct sense, like that of seeing or hearing; this would be truly the only definition that could be given, either of the sense or of its object; and all that we could do in investigating the nature of the latter, would be to digest and enumerate the circumstances under which it was found to present itself to its appropriate organ. All that we can say of colour, if we consider it very strictly, is, that it is that property in objects by which they are recommended to the faculty of sight; and the faculty of sight can scarcely be defined in any other way than as that by which we are enabled to discover the existence of colour. When we attempt to proceed farther, and say that green is the colour of grass, and red of roses or blood, it is plain that we do not in any respect explain the nature of those colours, but only *give instances* of their occurrence; and that one who had never seen them could learn nothing whatever from these pretended definitions. Complex ideas, on the other hand, and compound emotions, may be always defined, and explained to a certain extent, by enumerating the parts of which they are made up, or resolving them into the elements of which they are composed; and we may thus acquire not only a substantial knowledge of their nature, but a practical power in their regulation or production.

State of the question.

It becomes of importance, therefore, in the very outset of this inquiry, to consider whether our sense of beauty be really a simple sensation, like some of those we have enumerated, or a compound or derivative feeling, the sources or elements of which may be investigated and ascertained. If it be the former, we have then only to refer it to the peculiar sense or faculty of which it is the object, and to determine, by repeated observation, under what circumstances it occurs; but, if it be the latter, we have to proceed, by a joint process of observation and reflection, to ascertain what are the primary feelings to which it may be referred, and by what peculiar modification of them it is produced and distinguished. We are not quite prepared as yet to exhaust the whole of this important discussion, to which we shall be obliged to return in the sequel of our inquiry; but it is necessary, in order to explain and to set forth, in their natural order, the difficulties with which the subject is surrounded, to state here, in a very few words, one or two of the most obvious, and, as we think, decisive objections against the notion of beauty being a simple sensation, or the object of a separate and peculiar faculty.

The first, and perhaps the most considerable, is the want of agreement as to the presence and existence of beauty in particular objects, among men whose organization is perfect, and who are plainly possessed of the faculty, whatever it may be, by which beauty is discerned. Now,

First reason against the notion of beauty being a peculiar quality, and the object of a distinct sense or faculty.

no such thing happens, we imagine, or can be conceived to happen, in the case of any other simple sensation, or the exercise of any other distinct faculty. Where one man sees light, all men who have eyes see light also. All men allow grass to be green, and sugar to be sweet, and ice to be cold; and the unavoidable inference from any apparent disagreement in such matters necessarily is, that the party is insane, or entirely destitute of the sense or organ concerned in the perception. With regard to beauty, however, it is obvious at first sight that the case is quite different. One man sees it perpetually, where to another it is quite invisible, or even where its reverse seems to be conspicuous. Nor is this owing to the insensibility of either of the parties; for the same contrariety exists where both are keenly alive to the influences of the beauty they respectively discern. A Chinese or African lover would probably see nothing at all attractive in a belle of London or Paris; and, undoubtedly, an *elegans formarum spectator* from either of these cities would discover nothing but deformity in the Venus of the Hottentots. A little distance in time produces the same effects as distance in place: the gardens, the furniture, the dress, which appeared beautiful in the eyes of our grandfathers, are odious and ridiculous in ours. Nay, the difference of rank, education, or employments, gives rise to the same diversity of sensation. The little shopkeeper sees a beauty in his roadside box, and in the staring tile roof, wooden lions, and clipped boxwood, which strike horror into the soul of the student of the picturesque; whilst *he* is transported in surveying the fragments of ancient sculpture, which are nothing but ugly masses of mouldering stone in the judgment of the admirer of neatness. It is needless, however, to multiply instances, since the fact admits of no contradiction. But how can we believe that beauty is the object of a peculiar sense or faculty, when persons undoubtedly possessed of the faculty, and even in an eminent degree, can discover nothing of it in objects where it is distinctly felt and perceived by others with the same use of the faculty? This one consideration, we confess, appears to us conclusive against the supposition of beauty being a real property of objects, addressing itself to the power of taste as a separate sense or faculty, and seems to point irresistibly to the conclusion, that our sense of it is the result of other more elementary feelings, into which it may be analyzed or resolved.

Second reason.

A second objection, however, if possible of still greater force, is suggested by considering the prodigious and almost infinite variety of things to which this property of beauty is ascribed, and the impossibility of imagining any one inherent quality which can belong to them all, and yet at the same time possess so much unity as to be the peculiar object of a separate sense or faculty. All simple qualities that are perceived in any one object are immediately recognised to be *the same* when they are again perceived in another; and the objects in which they are thus perceived are at once felt so far to resemble each other, and to partake of the same nature. Thus snow is seen to be white, and chalk is seen to be white; but this is no sooner seen than the two substances, however unlike in other respects, are felt at once to have this quality in common, and to resemble each other in all that relates to the quality of colour and the sense of seeing. Now, is this felt, or could it even be intelligibly asserted, with regard to the quality of beauty? Take even a limited and specific sort of beauty,—for instance the beauty of form. The form of a fine tree is beautiful,—and the form of a fine woman,—and the form of a column, and a vase, and a chandelier. Yet how can it be said that the form of a woman has any thing in common with that of a tree or a temple? or to which of the senses by which forms are distinguished, does it appear they have any resemblance or affinity?

The matter, however, becomes still more inextricable when we recollect that beauty does not belong merely to forms or colours, but to sounds, and perhaps to the objects of other senses; nay, that in all languages and in all nations, it is not supposed to reside exclusively in material objects, but to belong also to sentiments and ideas, and intellectual and moral existences. Not only is a tree beautiful, as well as a palace or a waterfall; but a poem is beautiful, and a theorem in mathematics, and a contrivance in mechanics. But if things intellectual and totally segregated from matter may thus possess beauty, how can it possibly be a quality of material objects? Or what sense or faculty can that be, whose proper office it is to intimate to us the existence of some property which is common to a flower and a demonstration, a valley and an eloquent discourse?

Agreeableness of the objects of beauty not their common quality.

The only answer which occurs to this is plainly enough a bad one; but the statement of it, and of its inefficiency, will serve better, perhaps, than any thing else to develope the actual difficulties of the subject, and the true state of the question with regard to them. It may be said, then, in answer to the questions we have suggested above, that all these objects, however various and dissimilar, agree at least in being agreeable; and that this *agreeableness*, which is the only quality they possess in common, may probably be the beauty which is ascribed to them all. Now, to those who are accustomed to such discussions, it would be quite enough to reply, that though the agreeableness of such objects depends plainly enough upon their beauty, it by no means follows, but quite the contrary, that their beauty depends upon their agreeableness; the latter being the more comprehensive or generic term, under which beauty must rank as one of the species. Its nature, therefore, is no more explained, nor is less absurdity substantially committed, by saying that things are beautiful because they are agreeable, than if we were to give the same explanation of the sweetness of sugar; for no one, we suppose, will dispute, that though it be very true that sugar is agreeable because it is sweet, it would be manifestly preposterous to say that it was sweet because it was agreeable. For the benefit, however, of those who wish or require to be more regularly initiated in these mysteries, we beg leave to add a few observations.

In the first place, then, it seems evident that agreeableness in general cannot be the same with beauty, because there are very many things in the highest degree agreeable that can in no sense be called beautiful. Moderate heat, and savoury food, and rest, and exercise, are agreeable to the body; but none of these can be called beautiful: and, among objects of a higher class, the love and esteem of others, and fame, and a good conscience, and health, and riches, and wisdom, are all eminently agreeable; but not at all beautiful, according to any intelligible use of the word. It is plainly quite absurd, therefore, to say that beauty consists in agreeableness, without specifying in consequence of what it is agreeable; or to hold that any thing whatever is taught as to its nature, by merely classing it among our pleasurable emotions.

In the second place, however, we may remark, that among all the objects that are agreeable, whether they are also beautiful or not, scarcely any two are agreeable on account of the same qualities, or even suggest their agreeableness to the same faculty or organ. Most certainly there is no resemblance or affinity whatever between the qualities which make a peach agreeable to the palate, and a beautiful statue to the eye; which soothe us in an easy chair by the fire, or delight us in a philosophical discovery.

Beauty. The truth is, that agreeableness is not properly a quality of any object whatsoever, but the effect or result of certain qualities, the nature of which we can generally define pretty exactly, or of which we know at least with certainty that they manifest themselves respectively to some one particular sense or faculty, and to no other; and consequently it would be just as obviously ridiculous to suppose a faculty or organ, whose office it was to perceive agreeableness, as to suppose that agreeableness was a distinct quality that could thus be perceived.

The class of agreeable objects, thanks to the bounty of Providence, is exceedingly large. Certain things are agreeable to the palate, and others to the smell and to the touch. Some, again, are agreeable to our faculty of imagination, to our understanding, or to our moral feelings; and none of all these we call beautiful. But there are others which we do call beautiful; and those we say are agreeable to our faculty of taste: yet when we come to ask what is the faculty of taste, and what are the qualities which recommend them to that faculty, we find ourselves just where we were at the beginning of the discussion, and embarrassed with all the difficulties arising from the prodigious diversity of objects which seem to possess these qualities.

We know pretty well what is the faculty of seeing or hearing; or, at least, we know that what is agreeable to one of those faculties, has no effect whatever on the other. We know that bright colours afford no delight to the ear, nor sweet tones to the eye; and are therefore perfectly assured that the qualities which make the visible objects agreeable, cannot be the same with those which give pleasure to the ear. But it is by the eye and by the ear that all material beauty is perceived; and yet the beauty which discloses itself to these two separate senses, and plainly depends upon qualities which have no sort of affinity, is supposed to be one distinct quality, and to be perceived by a peculiar sense or faculty! The perplexity becomes still greater when we think of the beauty of poems or theorems, and endeavour to imagine what qualities they can possess in common with the agreeable modifications of light or of sound.

In what the difficulty of the subject truly consists. It is in these considerations undoubtedly that the difficulty of the subject consists. The faculty of taste, plainly, is not a faculty, like any of the external senses, the range of whose objects is limited and precise, as well as the qualities by which they are gratified or offended; and beauty, accordingly, is discovered in an infinite variety of objects, among which it seems at first sight impossible to discover any other bond of connection. Yet boundless as their diversity may appear, it is plain that they *must* resemble each other in *something*, and in something more definite and definable than in merely being agreeable; since they are all classed together, in every tongue and nation, under the common appellation of beautiful, and are felt indeed to produce emotions in the mind that have some sort of kindred or affinity. The words *beauty* and *beautiful*, in short, must mean something, and are universally felt to mean something, much more definite than agreeableness or gratification in general; and while it is confessedly by no means easy to describe or define what that something is, the force and clearness of our perception of it is demonstrated by the readiness with which we determine, in any particular instance, whether the object of a given pleasurable emotion is or is not properly described as beauty.

What we have already said, we confess, appears to us conclusive against the idea of this beauty being any fixed or inherent property of the objects to which it is ascribed, or itself the object of any separate and independent faculty; and we will no longer conceal from the reader what we take to be the true solution of the difficulty. In our opinion, then, our sense of beauty depends entirely on our previous experience of simpler pleasures or emotions, and consists in the *suggestion* of agreeable or interesting sensations with which we had formerly been familiar by the direct and intelligible agency of our common sensibilities; and that vast variety of objects, to which we give the common name of beautiful, become entitled to that appellation, merely because they all possess the power of recalling or reflecting those sensations of which they have been the accompaniments, or with which they have been associated in our imagination by any other more casual bond of connection. According to this view of the matter, therefore, beauty is not an inherent property or quality of objects at all, but the result of the accidental relations in which they may stand to our experience of pleasures or emotions,—and does not depend upon any particular configuration of parts, proportions, or colours, in external things, nor upon the unity, coherence, or simplicity of intellectual creations, but merely upon the associations which, in the case of every individual, may enable these inherent, and otherwise indifferent qualities, to suggest or recall to the mind emotions of a pleasurable or interesting description. It follows, therefore, that no object is beautiful in itself, or could appear so, antecedently to our experience of direct pleasures or emotions; and that, as an infinite variety of objects may thus reflect interesting ideas, so all of them may acquire the title of beautiful, although utterly diverse and disparate in their nature, and possessing nothing in common but this accidental power of reminding us of other emotions.

Beauty. Solution proposed.

This theory, which we believe is now very generally adopted, though under many needless qualifications, shall be further developed and illustrated in the sequel. But at present we shall only remark, that it serves at least to solve the great problem involved in the discussion, by rendering it easily conceivable how objects which have no inherent resemblance, nor indeed any one quality in common, should yet be united in one common relation, and consequently acquire one common epithet,—just as all the things that belonged to a beloved individual may serve to remind us of him, and thus to awake a kindred class of emotions, though just as unlike each other as any of the objects that are classed under the general name of beautiful. His poetry, for instance, or his slippers,—his acts of bounty, or his saddle-horse,—may lead to the same chain of interesting remembrances, and thus agree in possessing a power of excitement, for the sources of which we should look in vain through all the variety of their physical or metaphysical qualities.

By the help of the same consideration, we get rid of all the mystery of a peculiar sense or faculty, imagined for the express purpose of perceiving beauty; and discover that the power of taste is nothing more than the habit of tracing those associations, by which almost all objects may be connected with interesting emotions. It is easy to understand, that the recollection of any scene of delight or emotion must produce a certain agreeable sensation, and that the objects which introduce these recollections should not appear altogether indifferent to us: nor is it, perhaps, very difficult to imagine, that recollections thus strikingly suggested by some real and present existence should present themselves under a different aspect, and move the mind somewhat differently from those which arise spontaneously in the ordinary course of our reflections, and do not thus grow out of a direct and peculiar impression.

The whole of this doctrine, however, we shall endeavour by and by to establish upon more direct evidence; but having now explained, in a general way, both the

difficulties of the subject, and our suggestion as to their true solution, it is proper that we should take a short review of the more considerable theories that have been proposed for the elucidation of this curious question; which is one of the most delicate, as well as the most popular, in the science of metaphysics,—was one of the earliest which exercised the speculative ingenuity of philosophers,—and has at last, we think, been more successfully treated than any other of a similar description.

View of the theories proposed on the subject.

In most of these speculations we shall find rather imperfect truth than fundamental error,—or, at all events, such errors only as arise naturally from that peculiar difficulty which we have already endeavoured to explain, as consisting in the prodigious multitude and diversity of the objects in which the common quality of beauty was to be accounted for. Those who have not been sufficiently aware of the difficulty have generally dogmatized from a small number of instances, and have rather given examples of the occurrence of beauty in some few classes of objects, than afforded any light as to that upon which it essentially depended in all; whilst those who felt its full force have very often found no other resource than to represent beauty as consisting in properties so extremely vague and general (such, for example, as the power of exciting ideas of relation), as almost to elude our comprehension, and, at the same time, of so abstract and metaphysical a description, as not to be very intelligibly stated as the radicals of a strong, familiar, and pleasurable emotion. This last observation leads us to make one other remark upon the general character of these theories; and this is, that some of them seem necessarily to imply the existence of a peculiar sense or faculty for the perception of beauty, as they resolve it into properties that are not in any way interesting or agreeable to any of our known faculties. Such are all those which make it consist in proportion,—or in variety, combined with regularity,—or in waving lines,—or in unity,—or in the perception of relations,—without explaining, or attempting to explain, how any of these things should affect us with any delight or emotion. Others, again, do not require the supposition of any such separate faculty; because in them the sense of beauty is considered as arising from other more simple and familiar emotions, which are in themselves and beyond all dispute agreeable. Such are those which teach that beauty depends on the perception of utility, or of design, or of fitness, or in tracing associations between its objects and the common joys or emotions of our nature. Which of these two classes of speculation (to one or other of which, we believe, all theories of beauty may be reduced) is the most philosophical in itself, we imagine can admit of no question; and we hope, in the sequel, to leave it as little doubtful, which is to be considered as most consistent with the fact. In the meantime, we must give a short account of some of the theories themselves.

Speculations of Plato.

The most ancient of which it seems necessary to take any notice, is that which may be traced in the Dialogues of Plato,—though we are very far from pretending that it is possible to give any intelligible or consistent account of its tenor It should never be forgotten, however, that it is to this subtile and ingenious spirit that we owe the suggestion that it is *Mind* alone that is beautiful; and that, in perceiving beauty, it only contemplates the shadow of its own affections;—a doctrine which, however mystically unfolded in his writings, or however combined with extravagant or absurd speculations, unquestionably carries in it the germ of all the truth that has since been revealed on the subject. By far the largest dissertation, however, that this great philosopher has left upon the nature of beauty, is to be found in the dialogue entitled *The Greater Hippias*, which is entirely devoted to that inquiry. We do not learn a great deal of the author's own opinion, indeed, from this performance; for it is one of the dialogues which have been termed *anatreptic* or confuting,—in which nothing is concluded in the affirmative, but a series of sophistical suggestions or hypotheses are successively exposed. The plan of it is to lead on Hippias, a shallow and confident sophist, to make a variety of dogmatical assertions as to the nature of beauty, and then to make him retract and abandon them upon the statement of some obvious objections. Socrates and he agree at first in the notable proposition, " that beauty is that by which all beautiful things are beautiful;" and then, after a great number of suggestions, by far too childish and absurd to be worthy of any notice, such as, that the beautiful may peradventure be gold, or a fine woman, or a handsome mare, they at last get to some suppositions, which show that almost all the theories that have since been propounded on this interesting subject, had occurred thus early to the active and original mind of this keen and curious inquirer. Thus Socrates first suggests that beauty may consist in the fitness or suitableness of any object to the place it occupies; and afterwards more generally and directly, that it may consist in utility; a notion which is ultimately rejected, however, upon the subtile consideration that the useful is that which produces good, and that the producer and the product being necessarily different, it would follow, upon that supposition, that beauty could not be good, nor good beautiful. Finally, he suggests, that beauty may be the mere organic delight of the eye or the ear,—to which, after stating very slightly the objection, that it would be impossible to account upon this ground for the beauty of poetry or eloquence, he proceeds to rear up a more refined and elaborate refutation, upon such grounds as these: If beauty be the proper name of that which is naturally agreeable to the sight and hearing, it is plain that the objects to which it is ascribed must possess some common and distinguishable property besides that of being agreeable, in consequence of which they are separated and set apart from objects that are agreeable to our *other* senses and faculties, and, at the same time, classed together under the common appellation of beautiful. Now we are not only quite unable to discover what this property is, but it is manifest that objects which make themselves known to the ear *can* have no property as such in common with objects that make themselves known to the eye; it being impossible that an object which is beautiful by its colour, can be beautiful from the same quality with another which is beautiful by its sound. From all which it is inferred, that, as beauty is admitted to be something real, it cannot be merely what is agreeable to the organs of sight or hearing.

There is no practical wisdom, we admit, in those fine-drawn speculations; nor any of that spirit of patient observation by which alone any sound view of such objects can ever be attained. There are also many marks of that singular incapacity to distinguish between what is absolutely puerile and silly, and what is plausible, at least, and ingenious, which may be reckoned among the characteristics of " the divine philosopher," and in some degree of all the philosophers of antiquity: but they show clearly enough the subtile and abstract character of Greek speculation, and prove at how early a period, and to how great an extent, the inherent difficulties of the subject were felt, and produced their appropriate effects.

There are some hints on these subjects in the works of Xenophon, and some scattered observations in those of Cicero, who was the first, we believe, to observe that the sense of beauty is peculiar to man; but nothing else, we believe, in classical antiquity which requires to be analyzed or explained. It appears that St Augustin composed a

Beauty.

large treatise on beauty, and it is to be lamented that the speculations of that acute and ardent genius on such a subject have been lost. We discover, from incidental notices in other parts of his writings, that he conceived the beauty of all objects to depend on their unity, or on the perception of the principle or design which fixed the relations of their various parts, and presented them to the intellect or imagination as one harmonious whole. It would not be fair to deal very strictly with a theory with which we are so imperfectly acquainted: but it may be observed, that, while the author is so far in the right as to make beauty consist in a relation to mind, and not in any physical quality, he has taken far too narrow and circumscribed a view of the matter, and one which seems almost exclusively applicable to works of human art; it being plain enough, we think, that a beautiful landscape, or a beautiful horse, has no more unity, and no more traces of design, than one which is not beautiful.

Doctrine of St Augustin.

We do not pretend to know what the schoolmen taught upon this subject during the dark ages, but the discussion does not seem to have been resumed for long after the revival of letters. The followers of Leibnitz were pleased to maintain that beauty consisted in perfection; but what constituted perfection they did not attempt to define. M. Crouzas wrote a long essay to show that beauty depended on these five elements, variety, unity, regularity, order, and proportion; and the Père André, a still longer one to prove, that, admitting these to be the true foundations of beauty, it was still most important to consider, that the beauty which results from them is either essential, or natural, or artificial, and that it may be greater or less, according as the characteristics of each of these classes are combined or set in opposition.

Opinions of Crouzas and André;

of Lord Shaftesbury;

Among ourselves we are not aware of any considerable publication on the subject till the appearance of Lord Shaftesbury's *Characteristics*, in which a sort of rapturous Platonic doctrine is delivered as to the existence of a primitive and supreme good and beauty, and of a certain internal sense, by which both beauty and moral merit were distinguished. Addison published several ingenious papers in *The Spectator* on the pleasures of the imagination, and was the first, we believe, who referred them to the specific sources of beauty, sublimity, and novelty. He did not enter much, however, into the metaphysical discussion of the nature of beauty itself; and the first philosophical treatise of note that appeared on the subject may be said to have been the *Inquiry* of Dr Hutcheson, first published, we believe, in 1725.

of Addison.

Dr Hutcheson's doctrine.

In this work the notion of a peculiar internal sense, by which we are made sensible of the existence of beauty, is very boldly promulgated, and maintained by many ingenious arguments. Yet nothing, we conceive, can be more extravagant than such a proposition; and nothing but the radical faults of the other parts of the hypothesis could possibly have driven the learned author to its adoption. Even after the existence of this sixth sense was assumed, he felt that it was still necessary that he should explain what were the qualities by which it was gratified, and these, he was pleased to allege, were nothing but the combinations of variety with uniformity; all objects, as he has himself expressed it, which are equally uniform being beautiful in proportion to their variety, and all objects equally various being beautiful in proportion to their uniformity. Now, not to insist upon the obvious and radical objection that this is not true in fact, as to flowers, landscapes, or indeed of any thing but architecture, if it be true of that, it could not fail to strike the ingenious author that these qualities of uniformity and variety were not of themselves agreeable to any of our known senses or faculties, except when considered as symbols of utility or design, and therefore could not intelligibly account for the very lively emotions which we often experience from the perception of beauty, where the notion of design or utility was not at all suggested. He was constrained, therefore, either to abandon this view of the nature of beauty altogether, or to imagine a new sense or faculty, whose characteristic and description it should be to receive delight from the combinations of uniformity and variety, without any consideration of their being significant of things agreeable to our faculties; and this being accomplished by the mere force of the assumption and the definition, there was no room for further dispute or difficulty in the matter.

Beauty.

Some of Hutcheson's followers, such as Gerard and others, who were a little startled at the notion of a separate faculty, and yet wished to retain the doctrine of beauty depending on variety and uniformity, endeavoured, accordingly, to show that these qualities were *naturally* agreeable to the mind, and were recommended by considerations arising from its most familiar properties. Uniformity or simplicity, it is said, renders our conception of objects easy, and saves the mind from all fatigue and distraction in the consideration of them; whilst variety, if circumscribed and limited by an ultimate uniformity, gives it a pleasing exercise and excitement, and keeps its energies in a state of pleasurable activity. Now this appears to us to be mere trifling. The varied and lively emotions which we receive from the perception of beauty obviously have no sort of resemblance to the pleasure of moderate intellectual exertion; nor can any thing be conceived more utterly dissimilar than the gratification we have in gazing on the form of a lovely woman, and the satisfaction we receive from working an easy problem in arithmetic or geometry. If a triangle is more beautiful than a regular polygon, as those authors maintain, merely because its figure is more easily comprehended, the number *four* should be more beautiful than the number three hundred and twenty-seven, and the form of a gibbet far more agreeable than that of a branching oak. The radical error, in short, consists in fixing upon properties that are not interesting in themselves, and can never be conceived, therefore, to excite any emotion, as the fountain-spring of all our emotions of beauty; and it is an absurdity that must infallibly lead to others,—whether these take the shape of a violent attempt to disguise the truly indifferent nature of the properties so selected, or of the bolder expedient of creating a peculiar faculty, whose office it is to find them interesting.

Attempts to resolve beauty into uniformity and variety.

The next remarkable theory was that proposed by Edmund Burke, in his *Treatise of the Sublime and Beautiful*. But of this, in spite of the great name of the author, we cannot persuade ourselves that it is necessary to say much. His explanation is founded upon a species of materialism,—not much to have been expected from the general character of his genius, or the strain of his other speculations,—for it resolves entirely into this, that all objects appear beautiful which have the power of producing a peculiar relaxation of our nerves and fibres, and thus inducing a certain degree of bodily langour and sinking. Of all the suppositions that have been at any time hazarded to explain the phenomena of beauty, this, we think, is the most unfortunate, and the most weakly supported. There is no philosophy in the doctrine; and the fundamental assumption is in every way contradicted by the most familiar experience. There is no relaxation of the fibres in the perception of beauty, and there is no pleasure in the relaxation of the fibres. If there were, it would follow that a warm bath would be by far the most beautiful thing in the world, and that the brilliant lights and bracing airs of a fine autumn morning would be the very reverse

Theory of Burke.

Beauty

of beautiful. Accordingly, though the treatise alluded to will always be valuable on account of the many fine and just remarks it contains, we are not aware that there is any accurate inquirer into the subject (with the exception, perhaps, of Mr Price, in whose hands, however, the doctrine assumes a new character), by whom the fundamental principle of the theory has not been explicitly abandoned.

Theory of Diderot.

A yet more extravagant doctrine was soon afterwards inculcated, and in a tone of great authority, in a long article from the brilliant pen of Diderot, in the French *Encyclopédie*, and one which exemplifies, in a very striking manner, the nature of the difficulties with which the discussion is embarrassed. This ingenious person, perceiving at once that the beauty which we ascribe to a particular class of objects could not be referred to any peculiar and inherent quality in the objects themselves, but depended upon their power of exciting certain sentiments in our minds,—and being, at the same time, at a loss to discover what common power could belong to so vast a variety of objects as pass under the general appellation of beautiful, or by what tie all the various emotions which are excited by the perception of beauty could be united,—was at last driven, by his sense of the necessity of keeping his definition sufficiently wide and comprehensive, to hazard the strange assertion, that all objects were beautiful which excite in us the idea of *relation;* that our sense of beauty consisted in tracing out the relations which the object possessing it might have to other objects; and that its beauty was in proportion to the number and clearness of the relations thus suggested and perceived. It is scarcely necessary, we presume, to expose by any arguments the manifest fallacy, or rather the palpable absurdity, of such a theory as this. In the first place, we conceive it to be obvious, that all objects whatever have an infinite, and consequently an equal number of relations, and are equally likely to suggest them to those to whom they are presented: at all events, it is certain that ugly and disagreeable objects have just as many relations as those that are agreeable, and ought, therefore, to be just as beautiful, if the sense of beauty consists in the perception of relations. In the next place, it seems to be sufficiently certain, from the experience and common feelings of all men, that the perception of relations among objects is not in itself accompanied by any pleasure whatever, and in particular has no conceivable resemblance to the emotion we receive from the perception of beauty. When we perceive one ugly old woman sitting exactly opposite to two other ugly old women, and observe at the same moment that the first is as big as the other two taken together, we humbly conceive that this clear perception of the relations in which these three graces stand to each other cannot well be mistaken for a sense of beauty, and that it does not in the least abate or interfere with our sense of their ugliness. Finally, we may observe, that the sense of beauty results instantaneously from the perception of the object; whereas the discovery of its relations to other objects must necessarily be a work of time and reflection, in the course of which the beauty of the object, so far from being created or brought into notice, must, in fact, be lost sight of and forgotten.

Theory of Father Buffier and Sir Joshua Reynolds.

Another more plausible and ingenious theory was suggested by the Père Buffier, and afterwards adopted and illustrated with great talent in the *Discourses* of Sir Joshua Reynolds. According to this doctrine, beauty consists, as Aristotle held virtue to do, in mediocrity, or conformity to that which was most usual. Thus a beautiful nose, to make use of Dr Smith's very apt illustration of this doctrine, is one that is neither very long nor very short, very straight nor very much bent, but of an ordinary form and proportion compared with all the extremes. It is the form, in short, which nature seems to have aimed at in all cases, though she has more frequently deviated from it than hit it; but deviating from it in all directions, all her deviations come nearer to it than they ever do to each other. Thus the most beautiful in every species of creatures bears the greatest resemblance to the whole species, while monsters are so denominated because they bear the least; and thus the beautiful, though in one sense the rarest, as the exact medium is but seldom hit, is invariably the most common, because it is the central point from which all the deviations are the least remote. This view of the matter is adopted by Sir Joshua in its full extent, and is even carried so far by this great artist, that he does not scruple to conclude, "That if we were more used to deformity than beauty, deformity would then lose the idea that is now annexed to it, and take that of beauty;—just as we approve and admire fashions in dress, for no other reason than that we are used to them."

Beauty.

Now, not to dwell upon the very startling conclusion to which these principles must lead, viz. that things are beautiful in proportion as they are ordinary, and that it is merely their familiarity which constitutes their beauty, we would observe, in the first place, that the whole theory seems to have been suggested by a consideration of animal forms, or perhaps of the human figure exclusively. In these forms, it is quite true that great and monstrous deviations from the usual proportions are extremely disagreeable. But this, we have no doubt, arises entirely from some idea of pain or disaster attached to their existence, or from their obvious unfitness for the functions they have to perform. In vegetable forms, accordingly, these irregularities excite no such disgust; it being, in fact, the great object of culture, in almost all the more beautiful kinds, to produce what may be called monstrosities. And, in mineral substances, where the idea of suffering is still more completely excluded, it is notorious that, so far from the more ordinary configurations being thought the most beautiful, this epithet is scarcely ever employed but to denote some rare and unusual combination of veins, colours, or dimensions. As to landscapes, again, and almost all the works of art, without exception, the theory is plainly altogether incapable of application. In what sense, for example, can it be said that the beauty of natural scenery consists in mediocrity; or that these landscapes are the most beautiful that are the most common? or what meaning can we attach to the proposition, that the most beautiful building, or picture, or poem, is that which bears the nearest resemblance to all the individuals of its class, and is, upon the whole, the most ordinary and common?

To a doctrine which is liable to these obvious and radical objections, it is not perhaps necessary to make any other; but we must remark further, *first*, That it necessarily supposes that our sense of beauty is, in all cases, preceded by such a large comparison between various individuals of the same species, as may enable us to ascertain that average or mean form in which beauty is supposed to consist, and, consequently, that we could never discover any object to be beautiful antecedently to such a comparison; and, *secondly*, That, even if we were to allow that this theory afforded some explanation of the superior beauty of any one object compared with others of the same class, it plainly furnishes no explanation whatever of the superior beauty of one class of objects compared with another. We may believe, if we please, that one peacock is handsomer than another because it approaches more nearly to the average or mean form of peacocks in general; but this reason will avail us nothing whatever in ex-

plaining why any peacock is handsomer than any pelican or penguin. We may say, without manifest absurdity, that the most beautiful pig is that which has least of the extreme qualities that sometimes occur in the tribe; but it would be palpably absurd to give this reason, or any thing like it, for the superior beauty of the tribe of antelopes or spaniels.

The notion, in short, seems to have been hastily adopted by the ingenious persons who have maintained it, partly upon the narrow ground of the disgust produced by monsters in the animal creation, which has been already sufficiently explained,—and partly in consequence of the fallacy which lurks in the vague and general proposition of those things being beautiful which are neither *too* big nor *too* little, *too* massive nor *too* slender, &c.; from which it was concluded that beauty must consist in mediocrity:—not considering that the particle *too* merely denotes those degrees which are exclusive of beauty, without in any way fixing what those degrees are. For the plain meaning of these phrases is, that the rejected objects are too massive or too slender *to be beautiful;* and, therefore, to say that an object is beautiful which is neither too big nor too little, &c. is really saying nothing more than that beautiful objects are such as are not in any degree ugly or disagreeable. The illustration as to the effects of use or custom in the article of dress is singularly inaccurate and delusive; the fact being, that we never admire the dress which we are most accustomed to see,—which is that of the common people,—but the dress of the few who are distinguished by rank or opulence; and that we require no more custom or habit to make us admire this dress, whatever it may be, than is necessary to associate it in our thoughts with the wealth and dignity of those who wear it.

Opinions of Dr Gerard, Dr Blair, &c.

We need say nothing in this place of the opinions expressed on the subject of beauty by Dr Gerard, Dr Blair, and a whole herd of rhetoricians, because none of them pretend to have any new or original notions with regard to it, and, in general, have been at no pains to reconcile or render consistent the various accounts of the matter which they have contented themselves with assembling and laying before their readers altogether, as affording among them the best explanation that could be offered of the question. Thus they do not scruple to say, that the sense of beauty is sometimes produced by the mere organic affection of the senses of sight or hearing; at other times by a perception of a kind of regular variety; and in other instances by the association of interesting conceptions;—thus abandoning altogether any attempt to answer the radical question, how the feeling of beauty should be excited by such opposite causes,—and confounding together, without any attempt at discrimination, those theories which imply the existence of a separate sense or faculty, and those which resolve our sense of beauty into other more simple or familiar emotions.

Later and more important speculations.

More recently, however, we have had three publications on the subject, of a far higher character,—we mean Mr Alison's *Essays on the Nature and Principles of Taste,* Mr Payne Knight's *Analytical Inquiry* into the same objects, and Mr Dugald Stewart's Dissertations on the Beautiful, and on Taste, in his volume of *Philosophical Essays.* All these works possess an infinite deal of merit, and have among them disclosed almost all the truth that is to be known on the subject; though, as it seems to us, with some little admixture of error, from which it will not, however, be difficult to separate it.

Mr Alison maintains, that all beauty, or at least that all the beauty of material objects, depends on the associations that may have connected them with the ordinary affections or emotions of our nature; and in this, which is the fundamental point of his theory, we conceive him to be no less clearly right, than he is convincing and judicious in the copious and beautiful illustration by which he has sought to establish its truth. When he proceeds, however, to assert that our sense of beauty consists not merely in the suggestion of ideas of emotion, but in the contemplation of *a connected series* of such ideas, and indicates a state of mind in which the faculties, half active and half passive, are given up to a sort of reverie or musing, in which they may wander, though among kindred impressions, far enough from the immediate object of perception, we will confess that he not only seems to us to advance a very questionable proposition, but very essentially to endanger the evidence, as well as the consistency, of his general doctrine. We are far from denying, that, in minds of sensibility and of reflecting habits, the contemplation of beautiful objects will be apt, especially in moments of leisure, and when the mind is vacant, to give rise to such trains of thought, and to such protracted meditations; but we cannot possibly admit that their existence is necessary to the perception of beauty, or that it is in this state of mind exclusively that the sense of beauty exists. The perception of beauty, on the contrary, we hold to be, in most cases, quite instantaneous, and altogether as immediate as the perception of the external qualities of the object to which it is ascribed. Indeed, it seems only necessary to recollect, that it is to a present material object that we actually ascribe and refer this beauty, and that the only thing to be explained is, how this object comes to appear beautiful. In the long train of interesting meditations, however, to which Mr Alison refers,—in the delightful reveries in which he would make the sense of beauty consist,—it is obvious that we must soon lose sight of the external object which gave the first impulse to our thoughts; and though we may *afterwards* reflect upon it, with increased interest and gratitude, as the parent of so many charming images, it is impossible, we conceive, that the perception of *its* beauty can ever depend upon a long series of various and shifting emotions.

It likewise occurs to us to observe, that if every thing were beautiful which was the occasion of a train of ideas of emotion, it is not easy to see why objects that are called ugly should not be entitled to that appellation. If they are sufficiently ugly not to be viewed with indifference, they too will give rise to ideas of emotion; and those ideas are just as likely to run into trains and series as those of a more agreeable description. Nay, as contrast itself is one of the principles of association, it is not at all unlikely that, in the train of impressive ideas which the sight of ugly objects may excite, a transition may be ultimately made to such as are connected with pleasure; and, therefore, if the perception of the beauty of the object which first suggested them depended upon its having produced a series of ideas of emotion, or even of agreeable emotions, there seems to be no good reason for doubting that ugly objects may thus be as beautiful as any other, and that beauty and ugliness may be one and the same thing. Such is the danger, as it appears to us, of deserting the object itself, or going beyond its immediate effect and impression, in order to discover the sources of its beauty. Our view of the matter is safer, we think, and far more simple. We conceive the object to be associated, either in our past experience, or by some universal analogy, with pleasures or emotions that upon the whole are pleasant; and that these associated pleasures are instantaneously suggested, as soon as the object is presented, and by the first glimpse of its physical properties, with which, indeed, they are consubstantiated and confounded in our sensations.

Knight's theory.

The work of Mr Knight is more lively, various, and discursive, than Mr Alison's, but not so systematic or conclu-

Beauty.

sive. It is the cleverer book of the two, but not the most philosophical discussion of the subject. He agrees with Mr Alison in holding the most important, and, indeed, the only considerable part of beauty, to depend upon association; and has illustrated this opinion with a great variety of just and original observation. But he maintains, and maintains stoutly, that there is a beauty independent of association—prior to it, and more original and fundamental—the primitive and natural beauty of colours and sounds. Now this we look upon to be a heresy, and a heresy inconsistent with the very first principles of catholic philosophy. We shall not stop at present to give our reasons for this opinion, which we shall illustrate at large before we bring this article to a close; but we beg leave merely to suggest at present, that if our sense of beauty be confessedly in most cases the mere image or reflection of pleasures or emotions that have been associated with objects in themselves indifferent, it cannot fail to appear strange that it should also on some few occasions be a mere organic or sensual gratification of the particular organs. Language, it is believed, affords no other example of so whimsical a combination of different objects under one appellation, or of the confounding of a direct physical sensation with the suggestion of a social or sympathetic moral feeling. We would observe also, that while Mr Knight stickles so violently for this alloy of the senses in the constitution of beauty, he admits unequivocally, that sublimity is, in every instance and in all cases, the effect of association alone. Yet sublimity and beauty, in any just or large sense, and with a view to the philosophy of either, are manifestly one and the same; nor is it conceivable to us, that, if sublimity be *always* the result of an association with ideas of power or danger, beauty can possibly be, in any case, the result of a mere pleasurable impulse on the nerves of the eye or the ear. We shall return, however, to this discussion hereafter. Of Mr Knight we have only further to observe, that we think he is not less heretical in maintaining that we have no pleasure in sympathizing with distress or suffering, but only with mental energy; and that, in contemplating the sublime, we are moved only with a sense of power and grandeur, and never with any feeling of terror or awe. These errors, however, are less intimately connected with the subject of our present discussion.

Stewart's Essay.

With Mr Stewart we have less occasion for quarrel; chiefly, perhaps, because he has made fewer positive assertions, and entered less into the matter of controversy. His Essay on the Beautiful is rather philological than metaphysical. The object of it is to show by what gradual and successive extensions of meaning the word, though at first appropriated to denote the pleasing effect of *colours* alone, might naturally come to signify all the other pleasing things to which it is now applied. In this investigation he makes many admirable remarks, and touches, with the hand of a master, upon many of the disputable parts of the question; but he evades the particular point at issue between us and Mr Knight, by stating that it is quite immaterial to his purpose whether the beauty of colours be supposed to depend on their organic effect on the eye, or on some association between them and other agreeable emotions; it being enough for his purpose that this was probably the first sort of beauty that was observed, and that to which the name was at first exclusively applied. It is evident to us, however, that he leans to the opinion of Mr Knight, as to this beauty being truly sensual or organic. In observing, too, that beauty is not now the name of any one thing or quality, but of very many different qualities, and that it is applied to them all merely because they are often united in the same objects, or perceived at the same time and *by the same organs*, it appears to us that he carries his philology a little too far, and disregards other principles of reasoning of far higher authority. To give the name of beauty, for example, to every thing that interests or pleases us through the channel of sight, including in this category the mere impulse of light that is pleasant to the organ, and the presentment of objects whose whole charm consists in awakening the memory of social emotions, seems to us to be confounding things together that must always be separate in our feelings, and giving a far greater importance to the mere identity of the organ of perception than is warranted either by the ordinary language or ordinary experience of men. Upon the same principle, we should give this name of beautiful, and no other, to all acts of kindness or magnanimity, and, indeed, to every interesting occurrence which took place in our sight, or came to our knowledge by means of the eye: nay, as the ear is also allowed to be a channel for impressions of beauty, the same name should be given to any interesting or pleasant thing that we hear; and good news read to us from the gazette should be denominated beautiful, just as much as a fine composition of music. These things, however, are never called beautiful, and are felt, indeed, to afford a gratification of quite a different nature. It is no doubt true, as Mr Stewart has observed, that beauty is not one thing, but many, and does not produce one uniform emotion, but an infinite variety of emotions. But this, we conceive, is not merely because many pleasant things may be intimated to us by the same sense, but because the things that are called beautiful may be associated with an infinite variety of agreeable emotions, of the specific character of which their beauty will consequently partake. Nor does it follow, from the fact of this great variety, that there can be no other principle of union among these agreeable emotions than that of a *name*, extended to them all upon the very slight ground of their coming through the same organ; since, upon our theory, and indeed upon Mr Stewart's, in a vast majority of instances, there is the remarkable circumstance of their being all *suggested* by association with some present sensation, and all modified and compounded to our feelings by an actual and direct perception.

Beauty. Questionable doctrine.

It is unnecessary, however, to pursue these criticisms, or, indeed, this hasty review of the speculation of other writers, any further. The few observations we have already made will enable the intelligent reader both to understand in a general way what has been already done on the subject, and in some degree prepare him to appreciate the merits of that theory, substantially the same with Mr Alison's, which we shall now proceed to illustrate somewhat more in detail.

Further illustration of the theory of associations.

The basis of it is, that the beauty which we impute to outward objects is nothing more than the reflection of our own inward emotions, and is made up entirely of certain little portions of love, pity, and affection, which have been connected with these objects, and still adhere as it were to them, and move us anew whenever they are presented to our observation. Before proceeding to bring any proof of the truth of this proposition, there are two things which it may be proper to explain a little more distinctly; *first*,[1] What are the primary affections, by the suggestion of which we think the sense of beauty is pro-

[1] A considerable part of the sequel of this article has already appeared in a critique (by the same author) upon Mr Alison's *Essay*, in the *Edinburgh Review* for May 1811.

Beauty. duced? and, *secondly*, What is the nature of the connection by which we suppose that the objects we call beautiful are enabled to suggest these affections?

What affections may be the basis of beauty

With regard to the first of these points, it fortunately is not necessary either to enter into any tedious details, or to have recourse to any nice distinctions. All sensations that are not absolutely indifferent, and are, at the same time, either agreeable when experienced by ourselves, or attractive when contemplated in others, may form the foundation of the emotions of sublimity or beauty. The love of sensation seems to be the ruling appetite of human nature; and many sensations, in which the painful seems to bear no little share, are consequently sought for with avidity, and recollected with interest, even in our own persons. In the persons of others, emotions still more painful are contemplated with eagerness and delight; and therefore we must not be surprised to find, that many of the pleasing sensations of beauty or sublimity resolve themselves ultimately into recollections of feelings that may appear to have a very opposite character. The sum of the whole is, that every feeling which it is agreeable to experience, to recall, or to witness, may become the source of beauty in external objects, when it is so connected with them as that their appearance reminds us of that feeling. Now, in real life, and from daily experience and observation, we know that it is agreeable, in the first place, to recollect our own pleasurable sensations, or to be enabled to form a lively conception of the pleasures of other men, or even of sentient beings of any description. We know, likewise, from the same sure authority, that there is a certain delight in the remembrance of our past, or the conception of our future emotions, even though attended with great pain, provided they be not forced too rudely on the mind, and be softened by the accompaniment of any milder feeling. And, finally, we know, in the same manner, that the spectacle or conception of the emotions of others, even when in a high degree painful, is extremely interesting and attractive, and draws us away, not only from the consideration of indifferent objects, but even from the pursuit of light or frivolous enjoyments. All these are plain and familiar facts, of the existence of which, however they may be explained, no one can entertain the slightest doubt, and into which, therefore, we shall have made no inconsiderable progress, if we can resolve the more mysterious fact, of the emotions we receive from the contemplation of sublimity or beauty.

Our proposition then is, that these emotions are not original emotions, nor produced directly by any qualities in the objects which excite them; but are reflections or images of the more radical and familiar emotions to which we have already alluded, and are occasioned, not by any inherent virtue in the objects before us, but by the accidents, if we may so express ourselves, by which these may have been enabled to suggest or recall to us our own past sensations or sympathies. We might almost venture, indeed, to lay it down as an axiom, that, except in the plain and palpable case of bodily pain or pleasure, we can never be *interested* in any thing but the fortunes of sentient beings; and that every thing partaking of the nature of mental emotion must have for its object the feelings, past, present, or possible, of something capable of sensation. Independently, therefore, of all evidence, and without the help of any explanation, we should have been apt to conclude that the emotions of beauty and sublimity must have for their objects the sufferings or enjoyments of sentient beings; and to reject as intrinsically absurd and incredible the supposition, that material objects, which obviously do neither hurt nor delight the body, should yet excite, by their mere physical qualities, the very powerful emotions which are sometimes excited by the spectacle of beauty. Beauty.

Nature of the associations by which objects appear beautiful.

Of the feelings, by their connection with which external objects become beautiful, we do not think it necessary to speak more minutely; and therefore it only remains, under this preliminary view of the subject, to explain the nature of that connection by which we conceive this effect to be produced. Here, also, there is but little need for minuteness, or fulness of enumeration. Almost every tie by which two objects can be bound together in the imagination, in such a manner as that the presentment of the one shall recall the memory of the other, or, in other words, almost every possible relation which can subsist between such objects, may serve to connect the things we call sublime or beautiful, with feelings that are interesting or delightful. It may be useful, however, to class these bonds of association between mind and matter in a rude and general way.

It appears to us, then, that objects are sublime or beautiful, *first*, When they are the natural signs and perpetual concomitants of pleasurable sensations, or, at any rate, of some lively feeling or emotion in ourselves or in some other sentient beings; or, *secondly*, When they are the arbitrary or accidental concomitants of such feelings; or, *thirdly*, When they bear some analogy or fanciful resemblance to things with which these emotions are necessarily connected. In endeavouring to illustrate the nature of these several relations, we shall be led to lay before our readers some proofs that appear to us satisfactory of the truth of the general theory.

First class of associations.

The most obvious and the strongest association that can be established between inward feelings and external objects is, where the object is necessarily and universally connected with the feeling by the law of nature, so that it is always presented to the senses when the feeling is impressed upon the mind,—as the sight or the sound of laughter, with the feeling of gaiety,—of weeping, with distress,—of the sound of thunder, with ideas of danger and power. Let us dwell for a moment on the last instance. —Nothing, perhaps, in the whole range, is more strikingly and universally sublime than the sound we have just mentioned; yet it seems obvious that the sense of sublimity is produced, not by any quality that is perceived by the ear, but altogether by the impression of power and of danger that is necessarily made upon the mind whenever that sound is heard. That it is not produced by any peculiarity in the sound itself, is certain, from the mistakes that are frequently made with regard to it. The noise of a cart rattling over the stones is often mistaken for thunder; and as long as the mistake lasts, this very vulgar and insignificant noise is actually felt to be prodigiously sublime. It is so felt, however, it is perfectly plain, merely because it is then associated with ideas of prodigious power and undefined danger; and the sublimity is destroyed the moment the association is dissolved, though the sound itself, and its effect on the organ, continue exactly the same. This, therefore, is an instance in which sublimity is distinctly proved to consist, not in any physical quality of the object to which it is ascribed, but in its necessary connection with that vast and uncontrolled Power which is the natural object of awe and veneration.

Other examples.

We may now take an example a little less plain and elementary. The most beautiful object in nature, perhaps, is the countenance of a young and beautiful woman;—and we are apt at first to imagine, that, independently of all associations, the forms and colours which it displays are in themselves lovely and engaging, and would appear charming to all beholders, with whatever other qualities or impressions they might happen to be connected. A very little reflection, however, will probably be sufficient

Beauty. to convince us of the fallacy of this impression, and to satisfy us, that what we admire is not a combination of forms and colours, which could never excite any mental emotion, but a collection of signs and tokens of certain mental feelings and affections, which are universally recognised as the proper objects of love and sympathy. Laying aside the emotions arising from difference of sex, and supposing female beauty to be contemplated by the pure and unenvying eye of a female, it seems quite obvious that, amongst its ingredients, we should trace the signs of two different sets of qualities, that are neither of them the object of sight, but of a higher faculty;—in the first place, of youth and health; and, in the second place, of innocence, gaiety, sensibility, intelligence, delicacy or vivacity. Now, without enlarging upon the natural effect of these suggestions, we shall just suppose that the appearances, which must be admitted at all events to be actually significant of the qualities we have enumerated, had been by the law of nature attached to the very opposite qualities; —that the smooth forehead, the firm cheek, and the full lip, which are now so distinctly expressive to us of the gay and vigorous periods of youth,—and the clear and blooming complexion, which indicates health and activity,—had been in fact the forms and colours by which old age and sickness were characterized; and that, instead of being found united to those sources and seasons of enjoyment, they had been the badges by which nature pointed out that state of suffering and decay which is now signified to us by the livid and emaciated face of sickness, or the wrinkled front, the quivering lip, and hollow cheek of age: if this were the familiar law of our nature, can it be doubted that we should look upon these appearances, not with rapture, but with aversion,—and consider it as absolutely ludicrous or disgusting to speak of the beauty of what was interpreted by every one as the lamented sign of pain and decrepitude? Mr Knight himself, though a firm believer in the intrinsic beauty of colours, is so much of this opinion, that he thinks it entirely owing to those associations that we prefer the tame smoothness and comparatively poor colours of a youthful face, to the richly fretted and variegated countenance of a pimpled drunkard.

Such, we conceive, would be the inevitable effect of dissolving the subsisting connection between the animating ideas of hope and enjoyment, and those visible appearances which are now significant of these emotions, and derive their whole beauty from this signification. But the effect would be still stronger if we could suppose the *moral* expression of these appearances to be reversed in the same manner. If the smile which now enchants us as the expression of innocence and affection, were the sign attached by nature to guilt and malignity,—if the blush which expresses delicacy, and the glance that speaks intelligence, vivacity, and softness, had always been found united with brutal passion or idiot moodiness,—is it not certain that the whole of their beauty would be extinguished, and that our emotions from the sight of them would be exactly the reverse of what they now are?

Beauty of inanimate objects. That the beauty of a living and sentient creature should depend, in a great degree, upon the qualities peculiar to such a creature, rather than upon the mere physical attributes which it may possess in common with the inert matter around it, cannot indeed appear a very improbable supposition to any one. But it may be more difficult for some persons to understand how the beauty of mere dead matter should be derived from the feelings and sympathies of sentient beings. It is absolutely necessary, therefore, that we should give an instance or two of this derivation.

Beauty of landscapes. It is easy enough to understand how the sight of a picture or statue should affect us nearly in the same way as the sight of the original; nor is it much more difficult to conceive, how the sight of a cottage should give us something of the same feeling as the sight of a peasant's family, and the aspect of a town raise many of the same ideas as the appearance of a multitude of persons. We may begin, therefore, with an example a little more complicated. Take, for instance, the case of a common English landscape—green meadows, with fat cattle—canals or navigable rivers—well-fenced, well-cultivated fields—neat, clean, scattered cottages—humble antique church, with church-yard elms, and crossing hedge-rows—all seen under bright skies, and in good weather: there is much beauty, as every one will acknowledge, in such a scene. But in what does the beauty consist? Not certainly in the mere mixture of colours and forms; for colours more pleasing, and lines more graceful (according to any theory of grace that may be preferred), might be spread upon a board, or a painter's pallet, without engaging the eye to a second glance, or raising the least emotion in the mind; but in the picture of human happiness that is presented to our imaginations and affections,—in the visible and unequivocal signs of comfort, and cheerful and peaceful enjoyment,—and of that secure and successful industry that insures its continuance,—and of the piety by which it is exalted,—and of the simplicity by which it is contrasted with the guilt and the fever of a city life,—in the images of health and temperance and plenty which it exhibits to every eye,—and in the glimpses which it affords to warmer imaginations, of those primitive or fabulous times, when man was uncorrupted by luxury and ambition, and of those humble retreats in which we still delight to imagine that love and philosophy may find an unpolluted asylum. At all events, however, it is human feeling that excites our sympathy, and forms the object of our emotions. It is man, and man alone, that we see in the beauties of the earth which he inhabits;—or, if a more sensitive and extended sympathy connect us with the lower families of animated nature, and make us rejoice with the lambs that bleat on the uplands, or the cattle that ruminate in the valley, or even with the living plants that drink the bright sun and the balmy air beside them, it is still the idea of enjoyment—of feelings that animate the existence of sentient beings—that calls forth all our emotions, and is the parent of all the beauty with which we proceed to invest the inanimate creation around us.

Instead of this quiet and tame *English* landscape, let us now take a Welsh or a Highland scene, and see whether its beauties will admit of being explained on the same principle. Here we shall have lofty mountains, and rocky and lonely recesses,—tufted woods hung over precipices,—lakes intersected with castled promontories,—ample solitudes of unploughed and untrodden valleys,—nameless and gigantic ruins,—and mountain echoes repeating the scream of the eagle and the roar of the cataract. This, too, is beautiful; and, to those who can interpret the language it speaks, far more beautiful than the prosperous scene with which we have contrasted it. Yet, lonely as it is, it is to the recollection of man and of human feelings that its beauty also is owing. The mere forms and colours that compose its visible appearance, are no more capable of exciting any emotion in the mind, than the forms and colours of a Turkey carpet. It is sympathy with the present or the past, or the imaginary *inhabitants* of such a region, that alone gives it either interest or beauty; and the delight of those who behold it will always be found to be in exact proportion to the force of their imaginations, and the warmth of their social affections. The leading impressions here are those of romantic seclusion and primeval simplicity; lovers sequestered in these blissful solitudes, "from towns and toils remote;" and rustic poets and philosophers communing with nature, at a distance from the

Beauty. low pursuits and selfish malignity of ordinary mortals;—then there is the sublime impression of the Mighty Power which piled the massive cliffs upon one another, and rent the mountains asunder, and scattered their giant fragments at their base,—and all the images connected with the monuments of ancient magnificence and extinguished hostility—the feuds, and the combats, and the triumphs of its wild and primitive inhabitants, contrasted with the stillness and desolation of the scenes where they lie interred,—and the romantic ideas attached to their ancient traditions and the peculiarities of their present life,—their wild and enthusiastic poetry,—their gloomy superstitions,—their attachment to their chiefs,—the dangers, and the hardships, and enjoyments of their lonely huntings and fishings,—their pastoral shielings on the mountains in summer,—and the tales and the sports that amuse the little groups that are frozen into their vast and trackless valleys in the winter. Add to all this the traces of vast and obscure antiquity that are impressed on the language and the habits of the people, and on the cliffs, and caves, and gulfy torrents of the land,—and the solemn and touching reflection perpetually recurring, of the weakness and insignificance of perishable man, whose generations thus pass away into oblivion with all their toils and ambition, while nature holds on her unvarying course, and pours out her streams, and renews her forests, with undecaying activity, regardless of the fate of her proud and perishable sovereign.

Beauty of spring. We have said enough, we believe, to let our readers understand what we mean by external objects being the natural signs or concomitants of human sympathies or emotions. Yet we cannot refrain from adding one other illustration, and asking on what other principle we can account for the beauty of spring? Winter has shades as deep, and colours as brilliant, and the great forms of nature are substantially the same through all the revolutions of the year. We shall seek in vain, therefore, in the accidents of mere organic matter, for the sources of that "vernal delight and joy" which subject all finer spirits to an annual intoxication, and strike home the sense of beauty even to hearts that seem proof against it under all other aspects. And it is not among the dead, but among the living, that this beauty originates. It is the renovation of life and of joy to all animated beings that constitutes this great jubilee of nature,—the young of animals bursting into existence,—the simple and universal pleasures which are diffused by the mere temperature of the air and the profusion of sustenance,—the pairing of birds,—the cheerful resumption of rustic toils,—the great alleviation of all the miseries of poverty and sickness,—our sympathy with the young life, and the promise and the hazards of the vegetable creation,—the solemn yet cheering impression of the constancy of nature to her great periods of renovation,—and the hopes that dart spontaneously forward into the new circle of exertions and enjoyments that is opened up by her hand and her example. Such are some of the conceptions that are forced upon us by the appearances of returning spring, and that seem to account for the emotions of delight with which these appearances are hailed by every mind endowed with any degree of sensibility, somewhat better than the brightness of the colours, or the agreeableness of the smells, that are then presented to our senses.

Beauty of childhood. They are kindred conceptions that constitute all the beauty of childhood. The forms and colours that are peculiar to that age are not necessarily or absolutely beautiful in themselves; for, in a grown person, the same forms and colours would be either ludicrous or disgusting. It is their indestructible connection with the engaging ideas of innocence,—of careless gaiety,—of unsuspecting confidence, made still more tender and attractive by the recollection of helplessness, and blameless and happy ignorance,—of the anxious affection that watches over all their ways,—and of the hopes and fears that seek to pierce futurity, for those who have neither fears nor cares nor anxieties for themselves. Beauty.

These few illustrations will probably be sufficient to give our readers a general conception of the character and the grounds of that theory of beauty which, we think, affords the only true or consistent account of its nature. They are all examples, it will be observed, of the *first* and most important connection which we think may be established between external objects and the sentiments or emotions of the mind, or cases, in which the visible phenomena are the natural and universal accompaniments of the emotion, and are consequently capable of reviving that emotion, in some degree, in the breast of every beholder.

Second class of associations. If the tenor of those illustrations has been such as to make any impression in favour of the general theory, we conceive that it must be very greatly confirmed by the slightest consideration of the *second* class of cases, or those in which the external object is not the natural and necessary, but only the occasional or accidental, concomitant of the emotion which it recalls. In the former instances some conception of beauty seems to be inseparable from the appearance of the objects; and being impressed, in some degree, upon all persons to whom they are presented, there is evidently room for insinuating that it is an independent and intrinsic quality of their nature, and does not arise from association with any thing else. In the instances, however, to which we are now to allude, this perception of beauty is not universal, but entirely dependent upon the opportunities which each individual has had to associate ideas of emotion with the object to which it is ascribed; the same thing appearing beautiful to those who have been exposed to the influence of such associations, and indifferent to those who have not. Such instances, therefore, really afford an *experimentum crucis* as to the truth of the theory in question; nor is it easy to conceive any more complete evidence, both that there is no such thing as absolute or intrinsic beauty, and that it depends altogether on those associations with which it is thus found to come and to disappear.

Diversity of *national* tastes. The accidental or arbitrary relations that may thus be established between natural sympathies or emotions, and external objects, may be either such as occur to whole classes of men, or are confined to particular individuals. Among the former, those that apply to different nations or races of men, are the most important and remarkable; and constitute the basis of those peculiarities by which national tastes are distinguished. Take, again, for example, the instance of female beauty, and think what different and inconsistent standards would be fixed for it in the different regions of the world; in Africa, in Asia, and in Europe; in Tartary and in Greece; in Lapland, Patagonia, and Circassia. If there were any thing absolutely or intrinsically beautiful in any of the forms thus distinguished, it is inconceivable that men should differ so outrageously in their conceptions of it. If beauty were a real and independent quality, it seems impossible that it should be distinctly and clearly felt by one set of persons, where another set, altogether as sensitive, could see nothing but its opposite; and if it were actually and inseparably attached to certain forms, colours, or proportions, it must appear utterly inexplicable that it should be felt and perceived in the most opposite forms and proportions in objects of the same description. On the other hand, if all beauty consist in reminding us of certain natural sympathies and objects of emotion, with which they have been habitually connected, it is easy to perceive how

Beauty. the most different forms should be felt to be equally beautiful. If female beauty, for instance, consist in the visible signs and expressions of youth and health, and of gentleness, vivacity, and kindness; then it will necessarily happen, that the forms, and colours, and proportions which nature may have connected with these qualities, in the different climates or regions of the world, will all appear equally beautiful to those who have been accustomed to recognise them as the signs of such qualities; while they will be respectively indifferent to those who have not learned to interpret them in this sense, and displeasing to those whom experience has led to consider them as the signs of opposite qualities. The case is the same, though perhaps to a smaller degree, as to the peculiarity of national taste in other particulars. The style of dress and architecture in every nation, if not adopted from mere want of skill, or penury of materials, always appears beautiful to the natives, and somewhat monstrous and absurd to foreigners; and the general character and aspect of their landscape, in like manner, if not associated with substantial evils and inconveniences, always appears more beautiful and enchanting than the scenery of any other region. The fact is still more striking, perhaps, in the case of music; in the effects of those national airs, with which even the most uncultivated imaginations have connected so many interesting recollections; and in the delight with which all persons of sensibility catch the strains of their native melodies in strange or in distant lands. It is owing chiefly to the same sort of arbitrary and national association, that white is thought a gay colour in Europe, where it is used at weddings,—and a dismal colour in China, where it is used for mourning; that we think yew-trees gloomy, because they are planted in churchyards,—and large masses of powdered horse hair majestic, because we see them on the heads of judges and bishops.

Effect of education on taste. Next to those curious instances of arbitrary or limited associations that are exemplified in the diversities of national taste, are those that are produced by the differences of instruction or education. If external objects were sublime or beautiful in themselves, it is plain that they would appear equally so to those who were acquainted with their origin, and to those to whom it was unknown. Yet it is not easy, perhaps, to calculate the degree to which our notions of beauty and sublimity are now influenced over all Europe by the study of classical literature; or the number of impressions of this sort which the well-educated consequently receive, from objects that are utterly indifferent to uninstructed persons of the same natural sensibility. Upon this subject we gladly avail ourselves of the beautiful expressions of Mr Alison.

"The delight which most men of education receive from the consideration of antiquity, and the beauty that they discover in every object which is connected with ancient times, is in a great measure to be ascribed to the same cause. The antiquarian, in his cabinet, surrounded by the relics of former ages, seems to himself to be removed to periods that are long since past, and indulges in the imagination of living in a world which, by a very natural kind of prejudice, we are always willing to believe was both wiser and better than the present. All that is venerable or laudable in the history of these times presents itself to his memory. The gallantry, the heroism, the patriotism of antiquity, rise again before his view, softened by the obscurity in which they are involved, and rendered more seducing to the imagination by that obscurity itself, which, while it mingles a sentiment of regret amid his pursuits, serves at the same time to stimulate his fancy to fill up, by its own creation, those long intervals of time of which history has preserved no record. The relics he contemplates seem to approach him still nearer to the ages of his regard. The dress, the furniture, the arms of the times. are so many assistances to his imagination, in guiding or directing its exercise; and, offering him a thousand sources of imagery, provide him with an almost inexhaustible field in which his memory and his fancy may expatiate. There are few men who have not felt somewhat, at least, of the delight of such an employment. There is no man in the least acquainted with the history of antiquity, who does not love to let his imagination loose on the prospect of its remains, and to whom they are not in some measure sacred, from the innumerable images which they bring. Even the peasant, whose knowledge of former times extends but to a few generations, has yet in his village some monument of the deeds or virtues of his forefathers, and cherishes with a fond veneration the memorial of those good old times to which his imagination returns with delight, and of which he loves to recount the simple tales that tradition has brought him. Beauty

"And what is it that constitutes that emotion of sublime delight which every man of common sensibility feels upon the first prospect of Rome? It is not the scene of destruction which is before him. It is not the Tiber, diminished in his imagination to a paltry stream, flowing amid the ruins of that magnificence which it once adorned. It is not the triumph of superstition over the wreck of human greatness, and its monuments erected upon the very spot where the first honours of humanity have been gained. It is ancient Rome which fills his imagination. It is the country of Cæsar, and Cicero, and Virgil, which is before him. It is the mistress of the world which he sees, and who seems to him to rise again from her tomb, to give laws to the universe. All that the labours of his youth or the studies of his maturer age have acquired with regard to the history of this great people, opens at once before his imagination, and presents him with a field of high and solemn imagery, which can never be exhausted. Take from him these associations—conceal from him that it is Rome that he sees, and how different would be his emotion!"

The influences of the same studies may be traced, indeed, through almost all our impressions of beauty; and especially in the feelings which we receive from the contemplation of rural scenery, where the images and recollections which have been associated with such objects, in the enchanting strains of the poets, are perpetually recalled by their appearance, and give an interest and a beauty to the prospect, of which the uninstructed cannot have the slightest perception. Upon this subject, also, Mr Alison has expressed himself with his usual warmth and elegance. After observing that, in childhood, the beauties of nature have scarcely any existence for those who have as yet but little general sympathy with mankind, he proceeds to state that they are usually first recommended to notice by the poets, to whom we are introduced in the course of education; and who, in a manner, create them for us, by the associations which they enable us to form with their visible appearance.

"How different from this period become the sentiments with which the scenery of nature is contemplated by those who have any imagination! The beautiful forms of ancient mythology with which the fancy of poets peopled every element, are now ready to appear to their minds upon the prospect of every scene. The descriptions of ancient authors, so long admired, and so deserving of admiration, occur to them at every moment, and, with them, all those enthusiastic ideas of ancient genius and glory which the study of so many years of youth so naturally leads them to form. Or, if the study of modern poetry has succeeded to that of the ancient, a thousand

other beautiful associations are acquired, which, instead of destroying, serve easily to unite with the former, and to afford a new source of delight. The awful forms of Gothic superstition, the wild and romantic imagery which the turbulence of the middle ages, the crusades, and the institution of chivalry, have spread over every country of Europe, arise to the imagination in every scene; accompanied with all those pleasing recollections of prowess, and adventure, and courteous manners, which distinguished those memorable times. With such images in their minds, it is not common nature that appears to surround them. It is nature embellished and made sacred by the memory of Theocritus and Virgil, and Milton and Tasso; their genius appears still to linger among the scenes which inspired it, and to irradiate every object where it dwells; and the creation of their fancy seems the fit inhabitants of that nature which their descriptions have clothed with beauty."

Other effects.

It is needless, for the purpose of mere illustration, to pursue this subject of arbitrary or accidental association through all the divisions of which it is susceptible; and, indeed, the task would be endless, since there is scarcely any class in society which could not be shown to have peculiar associations of interest and emotion with objects which are not so connected in the minds of any other class. The young and the old—the rich and the poor—the artist and the man of science—the inhabitant of the city and the inhabitant of the country—the man of business and the man of pleasure—the domestic and the dissipated—nay, even the followers of almost every different study or profession,—have perceptions of beauty, because they have associations with external objects, that are peculiar to themselves, and have no existence for any other persons. But, though the detail of such instances could not fail to show, in the clearest and most convincing manner, how directly the notion of beauty is derived from some more radical and familiar emotion, and how many and various are the channels by which such emotions are transmitted, enough, perhaps, has been already said to put our readers in possession of the principles and general bearings of an argument which we must not think of exhausting.

The effect of fashion.

Before entirely leaving this branch of the subject, however, let us pause for a moment on the familiar but very striking and decisive instance of our varying and contradictory judgments as to the beauty of the successive fashions of dress that have existed within our own remembrance. All persons who still continue to find amusement in society, and are not old enough to enjoy only the recollections of their youth, think the prevailing fashions becoming and graceful, and the fashions of twenty or twenty-five years old intolerably ugly and ridiculous. The younger they are, and the more they mix in society, this impression is the stronger; and the fact is worth noticing, because there is really no one thing as to which persons judging merely from their feelings, and therefore less likely to be misled by any systems or theories, are so very positive and decided, as that established fashions are beautiful in themselves; and that exploded fashions are intrinsically and beyond all question preposterous and ugly. We have never yet met a young lady or gentleman, who spoke from their hearts, and without reserve, who had the least doubt on the subject, or could conceive how any person could be so stupid, as not to see the intrinsic elegance of the reigning mode, or not to be struck with the ludicrous awkwardness of the habits in which their mothers were disguised. Yet there can be no doubt, that if these ingenious critics had been born with the same natural sensibility to beauty, but twenty years earlier, they would have joined in admiring what they now laugh at, as certainly as those who succeed them twenty years hereafter will laugh at them. It is plain, then, and we think scarcely disputed out of the circles to which we have alluded, that there is, in the general case, no intrinsic beauty or deformity in any of those fashions; and that the forms, and colours, and materials, that are, we may say, universally and very strongly felt to be beautiful while they are in fashion, are sure to lose all their beauty as soon as the fashion has passed away. Now the forms, and colours, and combinations, remain exactly as they were; and, therefore, it seems perfectly obvious that the source of their successive beauty and ugliness must be sought in something extrinsic, and can only be found in the associations which once recommended and ultimately degraded them in our estimation. While they were in fashion, they were the forms and colours which distinguished the rich and the noble,—the eminent, the envied, the observed in society. They were the forms and the colours in which all that was beautiful, and admired, and exalted, were habitually arrayed. They were associated, therefore, with ideas of opulence, and elegance, and gaiety, and all that is captivating and bewitching in manners, fortune, and situation,—and derived the whole of their beauty from those associations. By and by, however, they were deserted by the beautiful, the rich, and the elegant, and descended to the vulgar and dependent, or were only seen in combination with the antiquated airs of faded beauties or obsolete beaux. They thus came to be associated with ideas of vulgarity and derision, and with the images of old and decayed persons, whom it is difficult for their juniors to believe ever to have been young or attractive;—and the associations being thus reversed, in which all their beauty consisted, the beauty itself naturally disappears.

The operation of the same causes is distinctly visible in all the other apparent irregularities of our judgments as to this description of beauty. Old people have in general but little toleration for the obsolete fashions of their later or middle years, but will generally stickle for the intrinsic elegance of those which were prevalent in the bright days of their early youth,—as being still associated in their recollections with the beauty with which they were first enchanted, and the gay spirits with which they were then inspired. In the same way, while we laugh at the fashions of which fine ladies and gentlemen were proud in the days of our childhood, because they are now associated only with images of decrepitude and decay, we look with some feelings of veneration on the habits of more remote generations, the individuals of which are only known to us as historical persons; and with unmingled respect and admiration on those still more ancient habiliments which remind us either of the heroism of the feudal chivalry, or the virtue and nobleness of classical antiquity. The iron mail of the Gothic knight, or the clumsy shield and naked arms of the Roman warrior, strike us as majestic and graceful, merely because they are associated with nothing but tales of romantic daring or patriotic prowess; while the full-bottomed periwigs that were added to the soldier's equipment in the days of Louis XIV. and King William, and no doubt had a noble effect in the eyes of that generation, now appear to us equally ridiculous and unbecoming, merely because such appendages are no longer to be seen but upon the heads of sober and sedentary lawyers, or in the pictures of antiquated esquires.

Associations peculiar to individuals.

We cannot afford, however, to enlarge any further upon these considerations, and are inclined indeed to think, that what has been already said on the subject of associations, which, though not universal, are common to whole classes of persons, will make it unnecessary to enlarge on those that are peculiar to each individual. It is almost

Beauty. enough, indeed, to transcribe the following short passage from Mr Alison.

"There is no man who has not some interesting associations with particular scenes, or airs, or books, and who does not feel their beauty or sublimity enhanced to him by such connections. The view of the house where one was born, of the school where one was educated, and where the gay years of infancy were passed, is indifferent to no man. They recall so many images of past happiness and past affections, they are connected with so many strong or valued emotions, and lead altogether to so long a train of feelings and recollections, that there is hardly any scene which one ever beholds with so much rapture. There are songs, also, that we have heard in our infancy, which, when brought to our remembrance in after years, raise emotions for which we cannot well account; and which, though perhaps very indifferent in themselves, still continue, from this association, and from the variety of conceptions which they kindle in our minds, to be our favourites through life. The scenes which have been distinguished by the residence of any person whose memory we admire produce a similar effect. *Movemur enim, nescio quo pacto, locis ipsis, in quibus eorum, quos diligimus aut admiramur, adsunt vestigia.* The scenes themselves may be little beautiful; but the delight with which we recollect the traces of their lives blends itself insensibly with the emotions which the scenery excites; and the admiration which these recollections afford seems to give a kind of sanctity to the place where they dwelt, and converts every thing into beauty which appears to have been connected with them."

There are similar impressions,—as to the sort of scenery to which we have long been accustomed,—as to the style of personal beauty by which we were first enchanted,—and even as to the dialect, or the form of versification, which we first began to admire,—that bestow a secret and adventitious charm upon all these objects, and enable us to discover in them a beauty which is invisible, because it is non-existent to every other eye.

Third class of associations.

In all the cases we have hitherto considered, the external object is supposed to have acquired its beauty by being actually connected with the causes of our natural emotions, either as a sign of their existence, or as being locally present to their ordinary occasions. There is a relation, however, of another kind, to which it is necessary to attend, both to elucidate the general grounds of the theory, and to explain several appearances that might otherwise expose it to objections. This is the relation which external objects may bear to our internal feelings, and the power they may consequently acquire of suggesting them, in consequence of a sort of resemblance or analogy which they seem to have to their natural and appropriate objects. The language of poetry is founded in a great degree upon this analogy; and all language, indeed, is full of it, and attests, by its structure, both the extent to which it is spontaneously pursued, and the effects that are produced by its suggestion. We take a familiar instance from the elegant writer to whom we have already referred.

"What, for instance, is the impression we feel from the scenery of spring? The soft and gentle green with which the earth is spread, the feeble texture of the plants and flowers, and the remains of winter yet lingering among the woods and hills,—all conspire to infuse into our minds somewhat of that fearful tenderness with which infancy is usually beheld. With such a sentiment, how innumerable are the ideas which present themselves to our imagination!—ideas, it is apparent, by no means confined to the scene before our eyes, or to the possible desolation which may yet await its infant beauty, but which almost involuntarily extend themselves to analogies with the life of man, and bring before us all those images of hope or fear which, according to our peculiar situations, have the dominion of our hearts. The beauty of autumn is accompanied with a similar exercise of thought: the leaves begin then to drop from the trees; the flowers and shrubs with which the fields were adorned in the summer months decay; the woods and groves are silent; the sun himself seems gradually to withdraw his light, or to become enfeebled in his power. Who is there who at this season does not feel his mind impressed with a sentiment of melancholy? or who is able to resist that current of thought which, from such appearances of decay, so naturally leads him to the solemn imagination of that inevitable fate which is to bring on alike the decay of life, of empire, and of nature itself?" Beauty.

Further illustrations.

A thousand such analogies, indeed, are suggested to us by the most familiar aspects of nature. The morning and the evening present the same ready picture of youth and of closing life as the various vicissitudes of the year. The withering of flowers images out to us the languor of beauty or the sickness of childhood. The loud roar of troubled waters seems to bear some resemblance to the voice of lamentation or violence; and the softer murmur of brighter streams, to be expressive of cheerfulness and innocence. The purity and transparency of water or of air, indeed, is itself felt to be expressive of mental purity and gaiety; and their darkness or turbulence, of mental gloom and dejection. The genial warmth of autumn suggests to us the feeling of mild benevolence;—the sunny gleams and fitful showers of early spring remind us of the waywardness of infancy;—flowers waving on their slender stems impress us with the notion of flexibility and lightness of temper. All fine and delicate forms are typical of delicacy and gentleness of character; and almost all forms bounded by waving or flowing lines suggest ideas of ease, pliability, and elegance. Rapid and impetuous motion seems to be emblematical of violence and passion;—slow and steady motion, of deliberation, dignity, and resolution;—fluttering motion, of inconstancy or terror;—and waving motion, according as it is slow or swift, of sadness or playfulness. A lofty tower or a massive building gives us the idea of firmness and elevation of character;—a rock battered by the waves, of fortitude in adversity. Stillness and calmness in the water or the air seem to shadow out tenderness, indolence, and placidity;—moonlight we call pensive and gentle;—and the unclouded sun gives us an impression of exulting vigour, and domineering ambition and glory.

Existence of certain analogies proved by the structure of language.

It is not difficult, with the assistance which language affords us, to trace the origin of all these and a thousand other associations. In many instances, the qualities which thus suggest mental emotions do actually resemble their constant concomitants in human nature, as is obviously the case with the forms and motions which are sublime or beautiful; and, in some, their effects and relations bear so obvious an analogy to those of human conduct or feeling, as to force itself upon the notice of the most careless beholder. But, whatever may have been their original, the very structure of language attests the vast extent to which they have been carried, and the nature of the suggestions to which they are indebted for their interest or beauty. If we speak familiarly of the sparkling of wit, and the darkness of melancholy, can it be at all difficult to conceive that bright light may be agreeable, because it reminds us of gaiety, and darkness oppressive, because it is felt to be emblematical of sorrow? It is very remarkable, indeed, that, whilst almost all the words by which the affections of the mind are expressed seem to have been borrowed originally from the qualities of matter, the

Beauty. epithets by which we learn afterwards to distinguish such material objects as are felt to be sublime or beautiful, are all of them epithets that had been previously appropriated to express some quality or emotion of mind. Colours are said to be gay or grave—motions to be lively, or deliberate, or capricious—forms to be delicate or modest—sounds to be animated or mournful—prospects to be cheerful or melancholy—rocks to be bold—waters to be tranquil—and a thousand other phrases of the same import; all indicating most unequivocally the sources from which our interest in matter is derived, and proving that it is necessary in all cases to confer mind and feeling upon it, before it can be conceived as either sublime or beautiful. The great charm, indeed, and the great secret of poetical diction, consists in thus lending life and emotion to all the objects it embraces; and the enchanting beauty which we sometimes recognise in descriptions of very ordinary phenomena, will be found to arise from the force of imagination, by which the poet has connected with human emotions a variety of objects, to which common minds could not discover their relation. What the poet does for his readers, however, by his original similes and metaphors in these higher cases, even the dullest of these readers do in some degree every day for themselves; and the beauty which is perceived, when natural objects are unexpectedly vivified by the glowing fancy of the former, is precisely of the same kind that is felt when the closeness of the analogy enables them to force human feelings upon the recollection of all mankind. As the poet sees more of beauty in nature than ordinary mortals, just because he perceives more of these analogies and relations to social emotion, in which all beauty consists; so, other men see more or less of this beauty, exactly as they happen to possess that fancy, or those habits, which enable them readily to trace out these relations.

From all these sources of evidence, then, we think it is pretty well made out, that the beauty or sublimity of external objects is nothing but the reflection of emotions excited by the feelings or condition of sentient beings, and is produced altogether by certain little portions, as it were, of love, joy, pity, veneration, or terror, that adhere to those objects which are present on occasion of such emotions. Nor, after what we have already said, does it seem to be necessary to reply to more than one of the objections to which we are aware that this theory is liable.

Objections answered. If beauty be nothing more than a reflection of love, pity, or veneration, how comes it, it may be asked, to be distinguished from these sentiments? They are never confounded with each other either in our feelings or our language. Why, then, should they all be confounded under the common name of beauty? and why should beauty, in all cases, affect us in a way so different from the love or compassion of which it is said to be merely the reflection?

Now, to these questions we are somewhat tempted to answer, after the manner of Scotchmen, by asking, in our turn, whether it be really true that beauty always affects us in one and the same manner, and always in a different manner from the simple and elementary affections which it is its office to recall to us? In very many cases it appears to us that the sensations which we receive from objects that are felt to be beautiful, and that in the highest degree, do not differ at all from the direct movements of tenderness or pity towards sentient beings. If the epithet of beauty be correctly (as it is universally) applied to many of the most admired and enchanting passages in poetry, which consist entirely in the expression of affecting sentiments, the question would be speedily decided; and it is a fact, at all events, too remarkable to be omitted, that some of the most powerful and delightful emotions that are uniformly classed under this name, arise altogether from the direct influence of these pathetic emotions, without the intervention of any material imagery. We do not wish, however, to dwell upon an argument which certainly is not applicable to all parts of the question; and, admitting that, on many occasions, the feelings which we experience from beauty are sensibly different from the primary emotions in which we think they originate, we shall endeavour, in a very few words, to give an explanation of this difference, which seems to be perfectly consistent with the theory we have undertaken to illustrate. Beauty.

Explanations. In the first place, it should make some difference on the primary affections to which we have alluded, that, in the cases alluded to, they are *reflected* from material objects, and not directly excited by their natural causes. The light of the moon has a very different complexion from that of the sun, though it is in substance the sun's light; and glimpses of interesting, or even of familiar objects, caught unexpectedly from a mirror placed at a distance from these objects, will affect us, like sudden allusions in poetry, very differently from the natural perception of those objects in their ordinary relations. In the next place, the emotion, when suggested in the shape of beauty, comes upon us, for the most part, disencumbered of all those accompaniments which frequently give it a peculiar and less satisfactory character, when it arises from direct intercourse with its living objects. The compassion, for example, that is suggested by beauty of a gentle and winning description, is not attended with any of that disgust and uneasiness which frequently accompany the spectacle of real distress, nor with that importunate suggestion of the duty of relieving it from which it is almost inseparable. Nor does the temporary delight which we receive from beauty of a gay and animating character, call upon us for any such expenditure of spirits, or active demonstrations of sympathy, as are sometimes demanded by the turbulence of real joy. In the third place, the emotion of beauty being partly founded upon illusion, is far more transitory in its own nature, and is both more apt to fluctuate and vary in its character, and more capable of being dismissed at pleasure, than any of the primary affections, whose shadow and representative it is. In the fourth place, the perception of beauty implies a certain exercise of the imagination that is not required in the case of direct emotion, and is sufficient of itself both to give a new character to every emotion that is suggested by the intervention of such an exercise, and to account for our classing all the various emotions that are so suggested under the same denomination of beauty. When we are injured we feel indignation,—when we are wounded we feel pain,—when we see suffering we feel compassion,—and when we witness any splendid act of heroism or generosity we feel admiration, without any effort of the imagination, or the intervention of any picture or vision in the mind. But when we feel indignation, or pity, or admiration, in consequence of seeing some piece of inanimate matter that merely suggests or recalls to us the ordinary causes or proper objects of these emotions, it is evident that our fancy is kindled by a sudden flash of recollection; and that the effect is produced by means of a certain poetical creation that is instantly conjured up in the mind. It is this active and heated state of the imagination, and this divided and busy occupation of the mind, that constitute the great peculiarity of the emotions we experience from the perception of beauty.

Finally, and this is perhaps the most important consideration of the whole, it should be recollected, that, along with the shadow or suggestion of associated emotions, there is always present a real and direct perception, which not only gives a force and liveliness to all the images which it suggests, but seems to impart to them some share of its

Beauty. own reality. That there is an illusion of this kind in the case, is sufficiently demonstrated by the fact, that we invariably ascribe the interest which we think has been proved to arise wholly from these associations, to the object itself, as one of its actual and inherent qualities, and consider *its* beauty as no less a property belonging to it than any of its physical attributes. The associated interest, therefore, is beyond all doubt confounded with the present perception of the object itself; and a livelier and more instant impression is accordingly made upon the mind, than if the interesting conceptions had been merely excited in the memory by the usual operation of reflection or voluntary meditation. Something analogous to this is familiarly known to occur in other cases. When we merely think of an absent friend, our emotions are incomparably less lively than when the recollection of him is suddenly suggested by the unexpected sight of his picture, of the house where he dwelt, or the spot on which we last parted from him; and all these objects seem for the moment to wear the colours of our own associated affections. When Captain Cook's companions found, in the remotest corner of the habitable globe, a broken spoon with the word *London* stamped upon it, and burst into tears at the sight, they proved how differently we are moved by emotions thus connected with the real presence of an actual perception, and by the mere recollection of the objects on which those emotions depend. Every one of them had probably thought of London every day since he left it, and many of them might have been talking of it with tranquillity but a little before this more effectual appeal was made to their sensibility.

If we add to all this, that there is necessarily something of vagueness and variableness in the emotions most generally excited by the perception of beauty, and that the mind wanders with the eye over the different objects which may supply these emotions with a degree of unsteadiness and half voluntary half involuntary fluctuation, we may come to understand how the effect not only should be essentially different from that of the simple presentment of any one interesting conception, but should acquire a peculiarity which entitles it to a different denomination. Most of the associations of which we have been last speaking, as being founded on the analogies or fanciful resemblances that are felt to exist between physical objects and qualities and the interesting affections of mind, are intrinsically of this vague and wavering description; and when we look at a fine landscape, or any other scene of complicated beauty, a great variety of such images are suddenly presented to the fancy, and as suddenly succeeded by others, as the eye ranges over the different features of which it is composed, and feeds upon the charms which it discloses. Now, the direct perception in all such cases not only perpetually accompanies the associated emotions, but is inextricably confounded with them in our feelings, and is even recognised upon reflection as the cause, not merely of their unusual strength, but of the several peculiarities by which we have shown that they are distinguished. It is not wonderful, therefore, either that emotions so circumstanced should not be classed along with similar affections, under circumstances extremely different, or that the perception of present existence, thus mixed up, and indissolubly confounded with interesting conceptions, should between them produce a sensation of so distinct a nature as naturally to be distinguished by a peculiar name, or that the *beauty* which results from this combination should, in ordinary language, be ascribed to the objects themselves, the presence and perception of which is a necessary condition of its existence.

What we have now said is enough, we believe, to give an attentive reader that general conception of the theory before us, which is all that we can hope to give in the limits to which this article is confined. It may be observed, however, that we have spoken only of those sorts of beauty which we think capable of being resolved into some passion, or emotion, or pretty lively sentiment of our nature; and though these are undoubtedly the highest and most decided kinds of beauty, it is certain that there are many things called beautiful which cannot claim so lofty a connection. Beauty.

It is necessary, therefore, to observe, that, though every thing that excites any feeling worthy to be called an *emotion* by its beauty or sublimity, will be found to be related to the natural objects of human passions or affections, there are many things which are pleasing or agreeable enough to be called beautiful in consequence of their relation merely to human convenience and comfort,—many others that please by suggesting ideas of human skill and ingenuity,—and many that obtain the name of beautiful by being associated with human fortune, vanity, or splendour. After what has been already said, it will not be necessary either to exemplify or explain these subordinate phenomena. It is enough merely to suggest that they all please upon the same great principle of sympathy with human feelings, and are explained by the simple and indisputable fact, that we are pleased with the direct contemplation of human comfort, ingenuity, and fortune. All these, indeed, obviously resolve themselves into the great object of sympathy—human enjoyment. Convenience and comfort is but another name for a lower but very indispensable ingredient of that emotion. Skill and ingenuity readily present themselves as means by which enjoyment may be promoted; and high fortune, and opulence, and splendour, pass, at least at a distance, for its certain causes and attendants. The beauty of fitness and adaptation of parts, even in the works of nature, is derived from the same fountain, partly by means of its obvious analogy to works of human skill, and partly by suggestions of that creative power and wisdom to which human destiny is subjected. The feelings, therefore, associated with all these qualities, though scarcely rising to the height of emotion, are obviously in a certain degree pleasing or interesting; and, when several of them happen to be united in one object, may accumulate to a very great degree of beauty. It is needless, we think, to pursue these general propositions through all the details to which they so obviously lead. We shall confine ourselves, therefore, to a very few remarks upon the beauty of architecture,—and chiefly as an illustration of our general position. Associations with ideas of comfort, genius, power, or splendour, are also sources of beauty.

There are few things about which men of *virtù* are more apt to rave, than the merits of the Grecian architecture; and most of those who affect an uncommon purity and delicacy of taste talk of the intrinsic beauty of its proportions as a thing not to be disputed, except by barbarian ignorance and stupidity. Mr Alison, we think, was the first who gave a full and convincing refutation of this mysterious dogma; and, while he admits, in the most ample terms, the beauty of the objects in question, he has shown, we think, in the clearest manner, that it arises entirely from the combination of the following associations:—1*st*, The association of utility, convenience, or fitness for the purposes of the building; 2*dly*, Of security and stability, with a view to the nature of the materials; 3*dly*, Of the skill and power requisite to mould such materials into forms so commodious; 4*thly*, Of magnificence, and splendour, and expense; 5*thly*, Of antiquity; and, 6*thly*, Of Roman and Grecian greatness. His observations are summed up in the following short sentence.

"The proportions," he observes, "of these orders, it is to be remembered, are distinct subjects of beauty, from the ornaments with which they are embellished, from the

Beauty. magnificence with which they are executed, from the purposes of elegance they are intended to serve, or the scenes of grandeur they are destined to adorn. It is in such scenes, however, and with such additions, that we are accustomed to observe them; and, while we feel the effect of all these accidental associations, we are seldom willing to examine what are the causes of the complex emotion we feel, and readily attribute to the nature of the architecture itself the whole pleasure which we enjoy. But, besides these, there are other associations we have with these forms, that still more powerfully serve to command our admiration; for they are the GRECIAN orders,—they derive their origin from those times, and were the ornament of those countries, which are most hallowed in our imaginations; and it is difficult for us to see them, even in their modern copies, without feeling them operate upon our minds as relics of those polished nations where they first arose, and of that greater people by whom they were afterwards borrowed."

This analysis is to us perfectly satisfactory. But, indeed, we cannot conceive any more complete refutation of the notion of an intrinsic and inherent beauty in the proportions of the Grecian architecture, than the fact of the admitted beauty of such very opposite proportions in the Gothic. Opposite as they are, however, the great elements of beauty are the same in this style as in the other,—the impressions of religious awe and of chivalrous recollections, coming here instead of the classical associations which constitute so great a share of the interest of the former. It is well observed by Mr Alison, that the great durability and costliness of the productions of this art have had the effect, in almost all regions of the world, of rendering their fashion permanent, after it had once attained such a degree of perfection as to fulfil its substantial purposes.

"Buildings," he observes, "may last, and are intended to last, for centuries. The life of man is very inadequate to the duration of such productions; and the present period of the world, though old with respect to those arts which are employed upon perishable subjects, is yet young in relation to an art which is employed upon so durable materials as those of architecture. Instead of a few years, therefore, centuries must probably pass before such productions demand to be renewed; and, long before that period is elapsed, the sacredness of antiquity is acquired by the subject itself, and a new motive given for the preservation of similar forms. In every country, accordingly, the same effect has taken place; and the same causes which have thus served to produce among us, for so many years, a uniformity of taste with regard to the style of Grecian architecture, have produced also among the nations of the East, for a much longer course of time, a similar uniformity of taste with regard to their ornamental style of architecture; and have perpetuated among them the same forms which were in use among their forefathers before the Grecian orders were invented."

It is not necessary, we think, to carry these illustrations any farther, as the theory they are intended to explain is now, we believe, universally adopted, though with some limitations, which we see no reason to retain. Those suggested by Mr Alison, we have already endeavoured to dispose of in the few remarks we have made upon his publication; and it only remains to say a word or two more upon Mr Knight's doctrine as to the primitive and independent beauty of colours, upon which we have already hazarded some remarks.

Knight's doctrine as to beauty of colours examined.

Agreeing as he does with Mr Alison, and all modern inquirers, that the whole beauty of objects consists, in the far greater number of instances, in the associations to which we have alluded, he still maintains that some few visible objects affect us with a sense of beauty in consequence of the pleasurable impression they make upon the sense, and that our perception of beauty is, in these instances, a mere organic sensation. Now we have already stated that it would be something quite unexampled in the history either of mind or of language, if certain physical and bodily sensations should thus be confounded with moral and social feelings with which they had no connection, and pass familiarly under one and the same name. Beauty consists confessedly, in almost all cases, in *the suggestion* of moral or social emotions, mixed up and modified by a present sensation or perception; and it is this suggestion, and this identification with a present object, that constitutes its essence, and gives a common character to the whole class of feelings it produces, sufficient to justify their being designated by a common appellation. If the word beauty, in short, must mean something, and if *this* be very clearly what it means in all remarkable instances, it is difficult to conceive that it should occasionally mean something quite different, and denote a mere sensual or physical gratification, unaccompanied by the suggestion of any moral emotion whatever. According to Mr Knight, however, and, indeed, to most other writers, this is the case with regard to the beauty of colours, which depends altogether, they say, upon the delight which the eye naturally takes in their contemplation; this delight being just as primitive and sensual as that which the palate receives from the contact of agreeable flavours.

Beauty.

Reasons for disputing this doctrine.

It must be admitted, we think, in the first place, that such an allegation is in itself extremely improbable, and contrary to all analogy, and all experience of the structure of language, or of the laws of thought. It is further to be considered, too, that if the pleasures of the senses are ever to be considered as beautiful, those pleasures which are the most lively and important would be the most likely to usurp this denomination, and to take rank with the higher gratifications that result from the perception of beauty. Now, it admits of no dispute, that the mere organic pleasures of the eye are far inferior to those of the palate, the touch, and indeed almost all the other senses,—none of which, however, are in any case confounded with the sense of beauty. In the next place, it should follow, that if what affords organic pleasure to the eye be properly called beautiful, what offends or gives pain to it should be called ugly. Now, excessive or dazzling light is offensive to the eye, but, considered by itself, it is never called ugly, but only painful or disagreeable. The moderate excitement of light, on the other hand, or the soothing of certain bright but temperate colours, when considered in this primary aspect, is scarcely called beautiful, but only agreeable or refreshing. So far as the direct injury or comfort of the organ, in short, is concerned, the language which we use refers merely to physical or bodily sensation, and is not confounded with that which relates to mental emotion; and we really see no ground for supposing that there is any exception to this rule.

It is very remarkable, indeed, that the sense whose organic gratification is here supposed to constitute the feeling of beauty, should be one, in the first place, whose direct organic gratifications are of very little force or intensity; and, in the next place, one whose office it is, almost exclusively, to make us acquainted with the existence and properties of those external objects which are naturally interesting to our inward feelings and affections. This peculiarity makes it extremely probable, that ideas of emotion should be *associated* with the perceptions of this sense, but extremely improbable that its naked and *unassociated* sensations should in any case be classed with

Beauty. such emotions. If the name of beauty were given to what directly gratifies any sense, such as that of tasting or smelling, which does *not* make us acquainted with the nature or relations of outward objects, there could be less room for such an explanation. But when it is the business of a particular sense or organ to introduce to our knowledge those objects which are naturally connected with ideas of emotion, it is easy to understand how its perceptions should be associated with these emotions, and an interest and importance thus extended to them, that belong to the intimations of no other bodily organ. But, on those very accounts, we should be prepared to suspect, that all the interest they possess is derived from this association; and to distrust the accuracy of any observations that may lead us to conclude that its mere organic impulses ever produced any thing akin to these associated emotions, or entitled to pass under their name. This caution will appear still more reasonable, when it is considered that all the other qualities of visible objects, except only their colours, are now admitted to be perfectly indifferent in themselves, and to possess no other beauty than they may derive from their associations with our ordinary affections. There are no *forms*, for example, even in Mr Knight's opinion, that have any intrinsic beauty, or any power of pleasing or affecting us, except through their associations, or affinities to mental affections, either as expressive of fitness and utility, or as types and symbols of certain moral or intellectual qualities, in which the sources of our interest are obvious. Yet the form of an object is as conspicuous an ingredient of its beauty as its colour, and a property, too, which seems at first view to be as intrinsically and independently pleasing. Why, then, should we persist in holding that colours, or combinations of colours, please from being *naturally* agreeable to the organ of sight, when it is admitted that other visible qualities, which *seem* to possess the same power of pleasing, are found, upon examination, to owe it entirely to the principle of association?

The only reason that can be assigned, or that actually exists, for this distinction, is, that it has been supposed more difficult to account for the beauty of colours, upon the principles which have accounted for other beauties, or to specify the particular associations by virtue of which they could acquire this quality. Now it appears to us that there is no such difficulty; and that there is no reason whatever for holding that one colour, or combination of colours, is more pleasing than another, except upon the same grounds of association which recommend particular forms, motions, or proportions. It appears to us, that the organic pleasures of the eye are extremely few and insignificant. It is hurt, no doubt, by an excessive glare of light; and it is in some degree gratified, perhaps, by a moderate degree of it. But it is only by the quantity or intensity of the light, we think, that it is so affected. The colour of it, we take it, is, in all cases, absolutely indifferent. But it is the colour only that is called beautiful or otherwise; and these qualities, we think, it very plainly derives from the common fountain of association.

Beauty of colours derived from association alone. In the first place, we would ask, whether there is any colour that is beautiful in all situations? and, in the next place, whether there is any colour that is not beautiful in some situation? With regard to the first, take the colours that are most commonly referred to as being intrinsically beautiful—bright and soft green—clear blue—bright pink, or vermilion. The first is unquestionably beautiful in vernal woods and summer meadows,—and, we humbly conceive, is beautiful because it is the natural sign and concomitant of those scenes and seasons of enjoyment. Blue, again, is beautiful in the vernal sky,—and, as we believe, for the sake of the pleasures of which such skies are prolific; and pink is beautiful on the cheeks of a young woman or the leaves of a rose, for reasons too obvious to be stated. We have associations enough, therefore, to recommend all these colours, in the situations in which they are beautiful; but, strong as these associations are, they are unable to make them universally beautiful.—or beautiful, indeed, in any other situations. Green would not be beautiful in the sky, nor blue on the cheek, nor vermilion on the grass. It may be said, indeed, that, though they are always recognised as beautiful in themselves, their obvious unfitness in such situations counteracts the effect of their beauty, and makes an opposite impression, as of something monstrous and unnatural; and that, accordingly, they are all beautiful in indifferent situations, where there is no such antagonist principle—in furniture, dress, and ornaments. Now the fact, in the first place, is not so;—these bright colours being but seldom and sparingly admitted in ornaments or works of art; and no man, for example, choosing to have a blue house, or a green ceiling, or a pink coat. But, in the second place, if the facts were admitted, we think it obvious that the *general* beauty of these colours would be sufficiently accounted for by the very interesting and powerful associations under which all of them are so frequently presented by the hand of nature. The interest we take in female beauty,—in vernal delights,—in unclouded skies,—is far too lively and too constantly recurring, not to stamp a kindred interest upon the colours that are naturally associated with such objects, and to make us regard with some affection and delight those hues that remind us of them, although we should only meet them upon a fan or a dressing-box, the lining of a curtain or the back of a screen. Finally, we beg leave to observe, that all bright and clear colours are naturally typical of cheerfulness and purity of mind, and are hailed as emblems of moral qualities, to which no one can be indifferent.

Beauty.

With regard to ugly colours, again, we really are not aware of any to which that epithet can safely be applied. Dull and dingy hues are usually mentioned as in themselves the least pleasing; yet these are the prevailing tints in many beautiful landscapes and many admired pictures. They are also the most common colours that are chosen for dress, for building, for furniture, where the consideration of beauty is the only motive for the choice. In fact, the shaded parts of all coloured objects pass into tints of this description; nor can we at present recollect any one colour which we could specify as in itself disagreeable, without running counter to the feelings and the practice of the great mass of mankind. If the fact, however, were otherwise, and if certain muddy and dull colours were universally allowed to be disagreeable, we should think there could be no difficulty in referring these, too, to natural associations. Darkness, and all that approaches it, is naturally associated with ideas of melancholy, of helplessness, and danger; and the gloomy hues that remind us of it, or seem to draw upon it, must share in the same associations. Lurid skies, too, it should be observed, and turbid waters, and unfruitful swamps, and dreary morasses, are the natural and most common wearers of these dismal liveries. It is from these that we first become acquainted with them; and it is needless, therefore, to say that such objects are necessarily associated with ideas of discomfort, and sadness, and danger; and that the colours that remind us of them can scarcely fail to recall some of the same disagreeable sensations.

Beauty of mixed or combined colours. Enough, however, and more than enough, has been said about the supposed primitive and independent beauty of separate colours. It is chiefly upon the intrinsic beauty of their mixture or combinations that Mr Knight and his adherents have insisted; and it is no doubt quite true, that, among painters and connoisseurs, we hear a great

Beauty. deal about the harmony and composition of tints, and the charms and difficulties of a judicious colouring. In all this, however, we cannot help suspecting that there is no little pedantry and no little jargon; and that these phrases, when used without reference to the practical difficulties of the art, which must go for nothing in the present question, really mean little more than the true and natural appearance of coloured objects, seen through the same tinted or partially obscure medium that commonly constitutes the atmosphere. In nature, we know of no discordant or offensive colouring, except what may be referred to some accident or disaster that spoils the moral or sentimental expression of the scene, and disturbs the associations upon which all its beauty, whether of forms or of hues, seems to us very plainly dependent. We are perfectly aware, that ingenious persons have been disposed to dogmatize and to speculate very confidently upon these subjects; and have had the benefit of seeing various learned treatises upon the natural *gamut* of colours, and the inherent congruity of those that are called complementary, with reference to the prismatic *spectrum*. But we confess we have no faith in any of those fancies; and believe, that, if all these colours were fairly arranged on a plain board, according to the most rigid rules of this supposed harmony, nobody but the author of the theory would perceive the smallest beauty in the exhibition, or be the least offended by reversing their collocation.

We do not mean, however, to dispute that the laws of colouring, insisted on by learned artists, will produce a more pleasing effect *upon trained judges of the art*, than a neglect of these laws; because we have little doubt that these combinations of colour are recommended by certain associations, which render them generally pleasing to persons so trained and educated;—all that we maintain is, that there are no combinations that are originally and universally pleasing or displeasing to the eye, independent of such associations; and it seems to us an irresistible proof of this, that these laws of harmonious colouring are perpetually and deliberately violated by great multitudes of persons, who not only have the perfect use of their sight, but are actually bestowing great pains and expense in providing for its gratification, in the very act of this violation. The Dutch trader, who paints over the outside of his country-house with as many bright colours as are to be found in his tulip-bed, and garnishes his green shutters with blue facings, and his purple roof with lilac ridges, not only sees as well as the studied colourist, who shudders at the exhibition, but actually receives as much pleasure, and as strong an impression of beauty, from the finished *lusthaus*, as the artist does from one of his best pictures. It is impossible, then, that these combinations of colours can be *naturally* or intrinsically offensive to the organ of sight; and their beauty or ugliness *must* depend upon the associations which different individuals may have happened to form with regard to them. We contend, however, for nothing more; and are quite willing to allow that the associations which recommend his staring tawdriness to the burgomaster, are such as could not easily have been formed in the mind of a diligent and extensive observer of nature, and that they would probably be reversed by habits of reflection and study. But the same thing, it is obvious, may be said of the notions of beauty of any other description that prevail among the rude, the inexperienced, and uninstructed; though, in all other instances, we take it for granted that the beauty which *is* perceived depends altogether upon association, and in no degree on its power of giving a pleasurable impulse to the organ to which it addresses itself. If any considerable number of persons, with the perfect use of sight, actually take pleasure in certain combinations of colours, *that* is complete proof that such combinations are not naturally offensive to the organ of sight, and that the pleasure of such persons, exactly like that of those who disagree with them, is derived, not from the sense, but from associations with its perceptions. Beauty.

With regard, again, to the effect of broken masses of light and shadow, it is proper, in the first place, to remember, that by the eye we see *colour only;* and that lights and shadows, as far as the mere organ is concerned, mean nothing but variations of tint. It is very true, no doubt, that we soon learn to refer many of those variations to light and shade, and that they thus become *signs* to us of depth, and distance, and relief. But is not this of itself sufficient to refute the idea of their affording any primitive or organic pleasure? In so far as they are mere variations of tints, they may be imitated by unmeaning daubs of paint on a pallet;—in so far as they are *signs*, it is to the mind that they address themselves, and not to the organ. They are signs, too, it should be recollected, and the only signs we have, by which we can receive any correct knowledge of the existence and condition of all external objects at a distance from us, whether interesting or not interesting. Without the assistance of variety of tint, and of lights and shadows, we could never distinguish one object from another, except by the touch. These appearances, therefore, are the perpetual vehicles of almost all our interesting perceptions; and are consequently associated with all the emotions we receive from visible objects. It is pleasant to see *many* things in one prospect, because some of them are probably agreeable; and it is pleasant to know the relations of those things, because the qualities or associations, by means of which they interest us, depend generally upon that knowledge. The mixture of colours and shades, however, is necessary to this enjoyment, and consequently is a sign of it, and a source of associated interest or beauty. Effects of light and shadow.

Mr Knight, however, goes much farther than this; and maintains, that the beauty which is so distinctly felt in many pictures of objects in themselves disagreeable, is to be ascribed entirely to the effect of the brilliant and harmonious tints, and the masses of light and shadow, that may be employed in the representation. The filthy and tattered rags of a beggar, he observes, and the putrefying contents of a dunghill, may form beautiful objects in a picture; because, considered as mere objects of sight, they may often present beautiful effects of colouring and shadow; and these are preserved or heightened in the imitation, disjoined from all their offensive accompaniments. Now, if the tints and shades were the exclusive sources of our gratification, and if this gratification was diminished, instead of being heightened, by the suggestion which, however transiently, *must* still intrude itself, that they appeared in an imitation of disgusting objects, it must certainly follow, that the pleasure and the beauty would be much enhanced if there was *no imitation of any thing whatever*, and if the canvass merely presented the tints and shades, unaccompanied with the representation, of any particular object. It is perfectly obvious, however, that it would be absurd to call such a collection of coloured spots a beautiful picture; and that a man would be laughed at who should hang up such a piece of stained canvass among the works of the great artists. Again, if it were really possible for any one but a student of art to confine the attention to the mere colouring and shadowing of any picture, there is nothing so disgusting but what might form the subject of a beautiful imitation. A piece of putrid veal, or a cancerous ulcer, or the rags that are taken from it, may display the most brilliant tints and the finest distribution of light and shadow. Does Mr Knight, however, seriously think that either of these experiments would Knight's opinion as to the beauty of certain pictures refuted.

Beauty. succeed? Or are there, in reality, no other qualities in the pictures in question, to which their beauty can be ascribed, but the organic effect of their colours? We humbly conceive that there are, and that far less ingenuity than his might have been able to detect them.

There is, in the first place, the pleasing association of the skill and power of the artist,—a skill and power which, we know, *may* be employed to produce unmingled delight, whatever may be the character of the particular effort before us. But, in the second place, we do humbly conceive that there are many interesting associations connected with the subjects which have been represented as purely disgusting. The aspect of human wretchedness and decay is not, at all events, an *indifferent* spectacle; and, if presented to us without actual offence to our senses, or any call on our active beneficence, may excite a sympathetic emotion, which is known to be far from undelightful. Many an attractive poem has been written on the miseries of beggars; and why should painting be supposed more fastidious? Besides, it will be observed that the beggars of the painter are generally among the most interesting of that interesting order;—either young and lovely children, whose health, and gaiety, and sweet expression, form an affecting contrast with their squalid garments, and the neglect and misery to which they seem to be destined,—or old and venerable persons, mingling something of the dignity and reverence of age with the broken spirit of their condition, and seeming to reproach mankind for exposing heads so old and white to the pelting of the pitiless storm. While such pictures suggest images so pathetic, it looks almost like a wilful perversity to ascribe their beauty entirely to the mixture of colours which they display, and to the forgetfulness of these images. Even for the dunghill we think it is possible to say something, though we confess we have never happened to see any picture of which that useful compound formed the peculiar subject. There is the display of the painter's art and power here also; and the dunghill is not only useful, but is associated with many pleasing images of rustic toil and occupation, and of the simplicity, and comfort, and innocence of agricultural life. We do not know that a dunghill is at all a disagreeable object to look at, even in plain reality, provided it be so far off as not to annoy us with its odour, or to soil us with its effusions. In a picture, however, we are safe from any of these disasters; and considering that it is usually combined, in such delineations, with other more pleasing and touching remembrancers of humble happiness and contentment, we really do not see that it was at all necessary to impute any mysterious or intrinsic beauty to its complexion, in order to account for the satisfaction with which we can then bear to behold it.

Beauty of sounds all derived from association.

Having said so much with a view to reduce to its just value, as an ingredient of beauty, the mere organical delight which the eye is supposed to derive from colours, we really have not patience to apply the same considerations to the alleged beauty of sounds that are supposed to be insignificant. Beautiful sounds in general, we think, are beautiful from association only,—from their resembling the natural tones of various passions and affections, or from their being originally and most frequently presented to us in scenes or on occasions of natural interest or emotion. With regard, again, to successive or co-existent sounds, we do not, of course, mean to dispute that there are such things as melody and harmony, and that most men are offended or gratified by the violation or observance of those laws upon which they depend. This, however, it should be observed, is a faculty quite *unique*, and unlike any thing else in our constitution; by no means universal, as the sense of beauty is, even in cultivated societies, and apparently withheld from whole communities of quick-eared savages and barbarians. Whether the kind of gratification which results from the mere musical arrangement of sounds would be referred to a sense of beauty, or would pass under that name, if it could be presented entirely detached from any associated emotions, appears to us to be exceedingly doubtful. Even with the benefit of these combinations, we do not find that every arrangement which merely preserves inviolate the rules of composition is considered beautiful; and we do not think that it would be consonant, either to the common feeling or common language of mankind, to bestow this epithet upon pieces that had no other merit. At all events, and whatever may be thought of the proper name of this singular gratification of a musical ear, it seems to be quite certain that all that rises to the dignity of an *emotion* in the pleasure we receive from sounds, is as clearly the gift of association as in the case of visible beauty,—of association with the passionate tones and modulations of the human voice,—with the scenes to which the interesting sounds are native,—with the poetry to which they have been married,—or even with the skill and genius of the artist by whom they have been arranged. Beauty.

Beauty of immaterial objects referable to the same sources.

Hitherto we have spoken of the beauty of external objects only. But the whole difficulty of the theory consists in its application to them. If that be once adjusted, the beauty of immaterial objects can occasion no perplexity. Poems, and other compositions in words, are beautiful in proportion as they are conversant with beautiful objects, or as they suggest to us, in a more direct way, the moral and social emotions on which the beauty of all objects depends. Theorems and demonstrations are beautiful, according as they excite in us emotions of admiration for the genius and intellectual power of their inventors, and images of the magnificent and beneficial ends to which such discoveries may be applied; and mechanical contrivances are beautiful when they remind us of similar talents and ingenuity, and at the same time impress us with a more direct sense of their vast utility to mankind, and of the great additional conveniences with which life is consequently adorned. In all cases, therefore, there is the suggestion of some interesting conception or emotion associated with a present perception, in which it is apparently confounded and embodied; and this, according to the whole of the preceding deduction, is the distinguishing characteristic of beauty.

Consequences of this theory.

Having now explained, as fully as we think necessary, the grounds of that opinion as to the nature of beauty which appears to be most conformable to the truth, we have only to add a word or two as to the necessary consequences of its adoption upon several other controversies of a kindred description.

In the first place, then, we conceive that it establishes the substantial identity of the sublime, the beautiful, and the picturesque, and consequently puts an end to all controversy that is not purely verbal as to the difference of those several qualities. Every material object that interests without actually hurting or gratifying our bodily feelings, must do so, according to this theory, in one and the same manner, that is, by suggesting or recalling some emotion or affection of ourselves or some other sentient being, and presenting, to our imagination at least, some natural object of love, pity, admiration, or awe. The interest of material objects, therefore, is always *the same*, and arises in every case, not from any physical qualities they may possess, but from their association with some idea of emotion. But, though material objects have but one means of exciting emotion, the emotions they do excite are infinite. They are mirrors that may reflect all shades and all colours, and, in point of fact, do seldom

Beauty. reflect the same hues twice. No two interesting objects, perhaps, whether known by the name of beautiful, sublime, or picturesque, ever produced exactly the same emotion in the beholder; and no one object, it is most probable, ever moved any two persons to the very same conceptions. As they may be associated with all the feelings and affections of which the human mind is susceptible, so they may suggest those feelings in all their variety, and, in fact, do daily excite all sorts of emotions, running through every gradation, from extreme gaiety and elevation, to the borders of horror and disgust.

Now, it is certainly true, that all the variety of emotions raised in this way, on the single basis of association, may be classed in a rude way under the denominations of sublime, beautiful, and picturesque, according as they partake of awe, tenderness, or admiration; and we have no other objection to this nomenclature except its extreme imperfection, and the delusions to which we know that it has given occasion. If objects that interest by their association with ideas of power, and danger, and terror, are to be distinguished by the peculiar name of sublime, why should there not be a separate name also for objects that interest by associations of mirth and gaiety,—another for those that please by suggestions of softness and melancholy,—another for such as are connected with impressions of comfort and tranquillity,—and another for those that are related to pity, and admiration, and love, and regret, and all the other distinct emotions and affections of our nature? These are not in reality less distinguishable from each other than from the emotions of awe and veneration that confer the title of sublime on their representatives; and while all the former are confounded under the comprehensive appellation of beauty, this partial attempt at distinction is only apt to mislead us into an erroneous opinion of our accuracy, and to make us believe both that there is a greater conformity among the things that pass under the same name, and a greater difference between those that pass under different names, than is really the case. We have seen already that the radical error of almost all preceding inquirers, has lain in supposing that every thing that passed under the name of beautiful must have some real and inherent quality in common with every thing else that obtained that name. And it is scarcely necessary for us to observe, that it has been almost as general an opinion, that sublimity was not only something radically different from beauty, but actually opposite to it; whereas the fact is, that it is far more nearly related to some sorts of beauty than many sorts of beauty are to each other; and that both are founded exactly upon the same principle of suggesting some past or possible emotion of some sentient being.

Upon this important point we are happy to find our opinions confirmed by the authority of Mr Stewart, who, in his Essay on the Beautiful, already referred to, has observed, not only that there appears to him to be no inconsistency or impropriety in such expressions as the *Sublime Beauties* of nature, or of the sacred Scriptures; but has added, in express terms, that, "to oppose the beautiful to the sublime, or to the picturesque, strikes him as something analogous to a contrast between the beautiful and the comic, the beautiful and the tragic, the beautiful and the pathetic, or the beautiful and the romantic."

The only other advantage which we shall specify as likely to result from the general adoption of the theory we have been endeavouring to illustrate, is, that it seems calculated to put an end to all these perplexing and vexatious questions about the standard of taste, which have given occasion to so much impertinent and so much elaborate discussion. If things are not beautiful in themselves, but only as they serve to suggest interesting conceptions to the mind, then every thing which does in point Beauty. of fact suggest such a conception to any individual, *is beautiful* to that individual; and it is not only quite true that there is no room for disputing about tastes, but that all tastes are equally just and correct, in as far as each individual speaks only of his own emotions. When a man calls a thing beautiful, however, he may indeed mean to make two very different assertions;—he may mean that it gives *him* pleasure, by suggesting to him some interesting emotion; and, in this sense, there can be no doubt that, if he merely speak truth, the thing is beautiful, and that it pleases him precisely in the same way that all other things please those to whom they appear beautiful. But if he mean further to say that the thing possesses some quality which should make it appear beautiful to every other person, and that it is owing to some prejudice or defect in them if it appear otherwise, then he is as unreasonable and absurd as he would think those who should attempt to convince him that he felt no emotion of beauty.

All tastes, then, are equally just and true, in as far as concerns the individual whose taste is in question; and what a man feels distinctly to be beautiful, *is beautiful* to him, whatever other people may think of it. All this follows clearly from the theory now in question: but it does not follow from it that all tastes are equally good or desirable, or that there is any difficulty in describing that which is really the best, and the most to be envied. The only use of the faculty of taste is to afford an innocent delight, and to aid the cultivation of a finer morality; and that man certainly will have the most delight from this faculty who has the most numerous and the most powerful perceptions of beauty. But if beauty consist in the reflection of our affections and sympathies, it is plain that *he* will always see the most beauty whose affections are warmest and most exercised, whose imagination is the most powerful, and who has most accustomed himself to attend to the objects by which he is surrounded. In as far as mere feeling and enjoyment are concerned, therefore, it seems evident that the best taste must be that which belongs to the best affections, the most active fancy, and the most attentive habits of observation. It will follow pretty exactly, too, that all men's perceptions of beauty will be nearly in proportion to the degree of their sensibility and social sympathies; and that those who have no affections towards sentient beings, will be just as insensible to beauty in external objects, as he who cannot hear the sound of his friend's voice must be deaf to its echo.

In so far as the sense of beauty is regarded as a mere source of enjoyment, this seems to be the only distinction that deserves to be attended to; and the only cultivation that taste should ever receive, with a view to the gratification of the individual, should be through the indirect channel of cultivating the affections and powers of observation. If we aspire, however, to be *creators* as well as observers of beauty, and place any part of our happiness in ministering to the gratification of others as artists, or poets, or authors of any sort—then, indeed, a new distinction of tastes, and a far more laborious system of cultivation, will be necessary. A man who pursues only his own delight will be as much charmed with objects that suggest powerful emotions in consequence of personal and accidental associations, as with those that introduce similar emotions by means of associations that are universal and indestructible. To him, all objects of the former class are really as beautiful as those of the latter—and, for his own gratification, the creation of that sort of beauty is just as important an occupation; but if he conceive the ambition of creating beauties for the admiration

of others, he must be cautious to employ only such objects as are the *natural* signs, or the *inseparable* concomitants of emotions, of which the greater part of mankind are susceptible; and his taste will *then* deserve to be called bad and false, if he obtrude upon the public, as beautiful, objects that are not likely to be associated in common minds with any interesting impressions.

For a man himself, then, there is no taste that is either bad or false; and the only difference worthy of being attended to, is that between a great deal and a very little. Some who have cold affections, sluggish imaginations, and no habits of observation, can with difficulty discern beauty in any thing; while others, who are full of kindness and sensibility, and who have been accustomed to attend to all the objects around them, feel it almost in every thing. It is no matter what other people may think of the objects of their admiration; nor ought it to be any concern of theirs that the public would be astonished or offended if they were called upon to join in that admiration. As long as no such call is made, this anticipated discrepancy of feeling need give *them* no uneasiness; and the suspicion of it should produce no contempt in any other person. It is a strange aberration indeed of vanity that makes us despise persons for being happy, for having sources of enjoyment in which we cannot share; and yet this is the true account of the ridicule which is so generally poured upon individuals who seek only to enjoy their peculiar tastes unmolested; for, if there be any truth in the theory we have been expounding, no taste is bad for any other reason than because it is peculiar, as the objects in which it delights must actually serve to suggest to the individual those common emotions and universal affections upon which the sense of beauty is everywhere founded. The misfortune is, however, that we are apt to consider all persons who make known their peculiar relishes, and especially all who create any objects for their gratification, as in some measure dictating to the public, and setting up an idol for general adoration; and hence this intolerant interference with almost all peculiar perceptions of beauty, and the unsparing derision that pursues all deviations from acknowledged standards. This intolerance, we admit, is often provoked by something of a spirit of *proselytism* and arrogance, in those who mistake their own casual associations for natural or universal relations; and the consequence is, that mortified vanity dries up the fountain of their peculiar enjoyment, and disenchants, by a new association of general contempt or ridicule, the scenes that had been consecrated by some innocent but accidental emotion.

As all men must have some peculiar associations, all men must have some peculiar notions of beauty, and, of course, to a certain extent, a taste that the public would be entitled to consider as false or vitiated. For those who make no demands on public admiration, however, it is hard to be obliged to sacrifice this source of enjoyment; and, even for those who labour for applause, the wisest course, perhaps, if it were only practicable, would be to have two tastes,—one to enjoy, and one to work by; one founded upon universal associations, according to which they finished those performances for which they challenged universal praise; and another guided by all casual and individual associations, through which they looked fondly upon nature, and upon the objects of their secret admiration. (F. J.)

BEAUVAIS (the *Cæsaromagus* and *Bellovaci* of antiquity), an arrondissement, department of Oise, in France, containing twelve cantons and 234 communes. Area 756 square miles. Pop. (in 1851) 101,983. The chief city, of the same name, is in a beautiful situation on the river Thérain, 21 miles N.W. of Paris. Pop. 12,508, employed in woollen, flax, cotton, earthenware, and carpet manufactures. The cathedral of Beauvais is one of the largest in France.

BEAVER, or Castor, an amphibious quadruped of the order *Rodentia*, with a thick glossy fur, and horizontally flattened tail, abounding in North America and Siberia, and still found in the north of Europe. It formerly appears to have been known as far south as the Rhone and the Danube; and though with us now extinct, was formerly an inhabitant of Great Britain. The fur of the beaver forms a considerable article of commerce. Among traders the skins are distinguished into three kinds: 1. The fresh beaver, which is obtained in winter, before the animal has shed any of its hair, and consequently that is most esteemed by furriers. 2. The dry or lean beaver, which is captured in summer, when the animal is moulting. 3. The fat beaver, which differs from the fresh only in having acquired additional softness and oiliness from being worn for some time on the persons of the native hunters. This is the kind that is chiefly used in hat-making. The substance called *castor* is found in pouches in the inguinal region of the beaver. It is regarded as a powerful antispasmodic. See Mammalia.

Beaver, that part of a helmet which covers the face.

BECAFICO, or Beccafigo (*Italian*), the fig-pecker, a bird like the nightingale, and much esteemed for its song and for its delicate flavour as food.

BECCAFUMI, Domenico Mecherino, was a painter of the school of Siena, where he was born in 1484, and where his best pictures are. His finest performances are small figures in distemper. He painted less happily in oil; but he is commended both by Vasari and by Lanzi. He died in 1549.

BECCARIA, Cæsar Bonesana, Marquis of, author of the well-known treatise on Crimes and Punishments, was born at Milan in the year 1735. His early studies were carried on in the college of the Jesuits at Parma. He possessed a quick apprehension; but, being naturally taciturn and inclined to reflection, he seldom communicated the progress of his ideas, and was with difficulty prevailed upon to complete his exercises. It is related, as another peculiarity of his disposition, that he never received praise from his teachers without betraying evident marks of pain and humiliation. These unusual indications of a susceptible mind, which, outstripping the course of his instructors, delighted in its own pursuits, and derived little complacency from a sense of its actual attainments, gave him, to common observers, a certain air of slowness, or even of stupidity, and characterized his features and deportment during the whole of his life. Having left college at the age of seventeen, he applied himself, with unremitting diligence, to the study of mathematics and the philosophy of man.

His propensity to the study of jurisprudence and political philosophy was first excited or confirmed by the *Lettre Persannes* of Montesquieu; a production capable, indeed, of alluring a less enthusiastic mind than that of Beccaria. But his industry in the pursuit of knowledge appears to have been chiefly stimulated by the patriotic and honourable desire of diffusing instruction among his countrymen, particularly the inhabitants of Milan, whom he represents, in one of his letters, as abandoned to a state of lamentable and universal ignorance. In the prosecution of these laudable designs, he fortunately possessed the confidence, and was encouraged by the protection, of Count Firmiani, then governor of that part of the Austrian dominions;—an accomplished nobleman, who, with comprehensive views of policy, concurred in every plan for improving the state of the provinces and the condition of their inhabitants.

Beccaria first appeared as an author in the year 1762,

Beccaria. when he published some observations on the Derangement of the Currency in the Milanese States, and a plan for its amendment. Soon after this he established a small literary society at Milan, in concert with some associates of character and sentiment similar to his own; among others, *Alessandro* and *Pietro Verri*, who at that time likewise contributed, by their talents and public spirit, to distinguish the reign of Maria Teresa in Lombardy.[1] Assisted by these friends, and countenanced by Firmiani, he commenced a periodical publication under the name of the *Caffè*; a plan said to have been suggested to them by the celebrity of Addison's *Spectator*, and the general belief of its influence on the opinions and taste of the people of England. Various papers, contributed by the members of this society, on subjects of literature, ethics, and physical science, were published during the years 1764 and 1765.

But by far the most remarkable production to which this society gave rise, and that by which the reputation of Beccaria has been chiefly perpetuated among other nations, was the treatise on Crimes and Punishments (*Dei Delitti e delle Pene*). This essay is said to have been undertaken at the earnest solicitation of Count Alexander Verri, who then discharged the functions of Protector of Prisoners (*Protettore de' Carcerati*) at the court of Milan. It was written at the house of his brother, Peter Verri, where the meetings of the society were held; and in concert with him the author, every evening, revised and corrected what he had written during the day. In this manner the work was completed within two months, and was printed in the course of the year 1764, with the mark of the Lucca press.[2]

In this small but noted work the author appears as the advocate of reason and sound policy no less than of humanity. It was his purpose, by examining the foundation, the objects, and consequently the boundaries, of penal law, to expose the inefficacy as well as injustice of many provisions in the judicial code of his own country, and in those of other European nations, which, derived from remote times, and established under a different order of society, had been perverted and debased during successive ages of barbarism. The authority of positive institutions formed almost the only basis of law, even in countries the furthest advanced in civilization; and that authority was in many of them drawn too servilely from the Roman system. Montesquieu had already thrown many penetrating glances at the foundation and structure of these ancient fabrics; but it was still reserved for others to scrutinize them more closely, and to draw forth, and present to general view, those direct inferences which that examination suggested. In no part were the existing codes more defective and vicious than in the department of the criminal law; and it was to this, accordingly, that Beccaria's attention was exclusively directed. Nor does he offer the work as a general system or theory even of penal law, in which light it would be found every way imperfect, but only as an attempt to analyze parts of a system which he found actually existing. Among the most prominent of those points to which his reasoning is applied, are, the due proportion between crime and punishment, and the violations of that proportion, whether by unnecessary severity of punishments, or the want of a scale and distribution of them suited to the amount and danger of particular offences; the inconsistency of certain rules then established on the subject of legal evidence; secret accusations, fictitious crimes, the use of torture as an instrument for the discovery of truth; imprisonment not authorized by law, or of uncertain duration, and the sale of offices of justice; along with other vices in the constitution of the courts. In treating these various topics, he seldom deduces his argument from remote sources, or pursues it to subtile refinements. That some propositions are advanced in the course of the work which are of a questionable nature, cannot be denied; and there are particular illustrations which have an exclusive reference to certain forms of government then existing in the Italian states. But, in general, the author reasons on few and acknowledged principles, and makes his appeal to the universal feelings of mankind. As one of the most important conclusions which result from his reasoning, or rather as concentrating a number of these conclusions, he closes his book with the following proposition: "In order that a punishment may not be an act of violence of one, or of many, against an individual member of society, it is essential that it should be public, prompt, and necessary, the least possible in the given case, and determined by the law." Beccaria.

His style in this work, with the exception of one or two passages, where he intentionally addresses himself only to the lesser number, is uniformly perspicuous, and, like that of all his other writings, though often eloquent, is unadorned. He employs, in some parts of it, that species of ridicule which, on a similar occasion, had been used with so great effect by Montesquieu. Thus, while treating the subject of torture, he proposes, among others, the following query in the form of a mathematical problem: "The force of the muscles and the sensibility of the nerves of an innocent person being given, it is required to find the degree of pain necessary to make him confess himself guilty of a given crime?" Peculiar traits of the writer's dispositions and train of sentiment are likewise to be found in other passages. Thus having, in a later edition, under that part which relates to fraudulent bankruptcy, modified some sentiments which he had originally expressed, but which, on reflection, appeared to himself too severe, he adds, in a note, "I am ashamed of what I formerly wrote on this subject. I have been accused of irreligion without deserving it; I have been accused of disaffection to the government, and deserved it as little; I was guilty of a real attack upon the rights of humanity, and I have been reproached by nobody."

If many of the views exhibited in this work are now divested of novelty, and if, through the general adoption of them by the most cultivated nations, we are led to forget that they were once hidden or excluded, such is the fate of all improvement as well as of all discovery. Nor does it detract from the true character of this interesting performance, that in some enlightened countries, and in the more propitious climates of political liberty, many of the important doctrines which it inculcated were already recognised in the systems of the law.[3] Beccaria was

---

[1] A small publication which appeared about that time, under the title of *Thoughts on Happiness*, was written by the former. His literary pursuits were, soon after, suspended by his appointment to a public situation.

[2] These particulars, communicated in a letter of Count A. Verri to the Abbate Isidoro Bianchi, in 1802, are repeated by the latter in his *Elogio* on Pietro Verri.

[3] In the most favoured countries of liberty, however, the reception of some of these principles had been comparatively recent; while of others, the establishment seems even yet to be remote. That work which has tended most to diffuse a knowledge of the progress and spirit of the English laws, viz. the *Commentaries* of Sir William Blackstone, was not published till the close of the year 1765, although his plan of delivering a public lecture on the judicial system of his country was formed in 1753. The professorship at Oxford, which gave full effect to that plan, was instituted by Mr Viner in 1758.

 among the first by whom these principles were publicly avowed, under a government in whose institutions they had no place, and over whose judicial administration they exercised no influence; and, when the age and country in which he wrote are considered, the boldness of his statements is not less to be admired than the justness of his reasoning. It is his honourable distinction, likewise, and that of the friends who shared his labours and his views, to have preserved, in the prosecution of these objects, an unblemished loyalty towards their prince, and, while combating, with manly perseverance, the errors which prevailed in the fundamental principles of legislation, to have abstained from all attacks which might either directly weaken the authority of the laws, or disturb the administration of the government.

According to the just exposition given by the author himself, the true tendency of such a work is not to lessen the power of the law, but to increase its influence, inasmuch as opinion has a greater command over the minds of men than force. It has frequently been repeated, indeed, that national manners must precede laws; and in the only allowable sense of that maxim, the same might be said, perhaps, with equal truth, of opinions. But the authority of this *dictum*, and the extent to which it may be followed, are not unfrequently mistaken. An important distinction is apt to be overlooked, between those general laws, which, as they are founded in permanent principles of our nature, admit of being drawn from the first springs, but which have been disturbed by ignorance, or a barbarous policy, or the temporary dominion of some prevailing passion—and those artificial or secondary arrangements, which the circumstances and stages of political society may equally render necessary in times of knowledge, and tranquillity, and civilization. It is to the latter class only that the maxim referred to can have any just application. But it may well be questioned, whether, in any case whatever, the popular feeling and opinion should be allowed to precede, by any considerable interval, the act of the legislature. It seems, on the contrary, to be a valuable secret in legislation, and one of its most important ends, to seize the proper moment for accomplishing that union. Above all, it is expedient, in those branches of the law which are interwoven with and derive their support from the moral feelings, that a legislator should seek to anticipate every better tendency of public sentiment. Through want of a well-timed interference in such cases, many advantages are relinquished, as well in the concocting and framing of the laws themselves, as in that silent influence which a well-directed system of jurisprudence carries into the opinions and habits of a community.

Of the prospects which Beccaria himself entertained as to the probable influence of his work, a judgment may be formed from the sentence of Lord Bacon, which he prefixed to some of the editions. "It is not to be expected in any difficult undertaking, of whatever kind, that the same person who sows the seed should also reap the harvest; but there must, of necessity, be a preparation, and gradual progress to maturity."

The book was received in foreign countries with avidity, and procured for its author an immediate and high reputation. "Never," says a writer in the *Biographie Universelle*, "did so small a book produce so great an effect." The medal given by the Academy of Bern was instantly bestowed upon Beccaria; and the empress Catherine II. invited him to St Petersburg, with the offer of an honourable station at her court; a proposal which was partly the means of procuring him a similar distinction at home. Of the reception which the work obtained in France, particularly among the literary societies of Paris, evidence is afforded by the correspondence of the Baron de Grimm. "This book," he writes, in a letter dated 1st August 1765, "is by M. Beccaria, a Milanese gentleman, who is said by some to be an abbé, by others a lawyer, but who, I answer for it, is one of the best heads at this moment in Europe." "You will not find in the Milanese philosopher," he elsewhere observes, "either the pitch or compass of genius which characterize the writings of the President Montesquieu; but you will discover a mind that is luminous, profound, correct, and penetrating." And he justly adds, that his is one of the few precious books, *qui font penser*. It was translated into French by the Abbé Morellet in 1766; and Voltaire soon after published a commentary upon it, under the assumed title of *Un Avocat de Besançon*. With respect to the former production, the translator took some liberties with the method and distribution of the work, which were not altogether warrantable. Voltaire's commentary is written in the light style peculiar to him; and was evidently intended as a vehicle for certain opinions of his own, with which the spirit and object of the original publication are entirely unconnected. But the circumstance itself sufficiently marks the impression which that publication had made, and the prominence of the views which it developed. It was rapidly translated into various other languages; its maxims became a species of current coin through a great part of Europe; and the sanction of the author's reasoning was thought not unworthy of being resorted to in British tribunals.

Although followed by many others, Beccaria's was the first work of note, in which the application of a milder and more sound system of penal jurisprudence was explicitly enforced. Nor would it be at all extravagant to refer some of the great improvements which from this era were successively introduced into the written laws of different European monarchies, to the direct influence of the opinions thus generally diffused. Many such enactments, at least, were from this time promulgated in a tone more consonant than heretofore with the dictates of humanity and equitable rule. Of this description were, among others, not only the *urbarium*, or regulations concerning villanage, issued in 1764, by the empress Maria Teresa, but also the more extended designs which took effect, at a somewhat later period, in the various reformed codes, published by the empress Catherine, the emperor Joseph II., the grand duke of Tuscany, and the Danish government under the administration of the late Count Bernstorf.

At one period a storm seemed to be preparing against the marquis in his own country, by those who probably intended, in this form, a service to the government; but it was soon dispersed by the authority of the government itself. Beccaria had considered it his duty to communicate to Count Firmiani the offers which had been made to him by the empress Catherine, and the intelligence was transmitted by the viceroy to his own court. The conduct of Prince Kaunitz-Ritzberg, on the occasion, is highly honourable to that minister and to his sovereign. Instead of treating the communication as a matter of no account, he makes it the subject of a long dispatch, and of repeated instructions. In one of these papers, dated 27th April 1767, after requiring particular information respecting the personal character of Beccaria, he adds, "Supposing his good qualities to preponderate, it would be desirable that the country should not lose a man whose fund of knowledge is so considerable, and who, as appears from his book, possesses a mind habituated to reflection, above all in our present penury of thinking and philosophical men; besides that it would do little honour to the whole administration to be anticipated by foreigners in the due

Beccaria. estimation of talents."[1] Nor were these merely empty professions; they were almost immediately followed by an imperial order for establishing, in the palatine college at Milan, a professorship of public law and economics, under the title of *Scienze Camerali*. To this chair, expressly endowed for him by a distinction so honourable, the marquis was appointed on the 1st of November 1768, and commenced the duties of it in the month of January following. From the preliminary discourse (*proluzione*) which he pronounced on this occasion, and in which he briefly sets forth the objects of the institution, and some of his own leading opinions regarding them, it appears that the only instructions which he received from the regency on his appointment, consisted in an order to deliver his discourses in the vulgar tongue; an injunction of which the motives are honourable to that government, in common with all the circumstances attending this transaction. His lectures, which he received a special permission to deliver in his own house, attracted much notice. They were not published during his life; but have since appeared, under the title of *Elementi di Economia Pubblica*, in the compilation of the *Scrittori Classici Italiani di Economia Politica*, printed at Milan.[2]

As he had, in his former work, set out with stating the object of municipal law to be "the greatest happiness of the greatest number," so here the same universal principle serves him for a guide; and he assumes it as the aim of public economy "to provide with peace and safety, things necessary and convenient for the whole community." He classes the objects of political economy under five heads; agriculture, manufactures, commerce, finance, and policy; comprehending, under the latter, those laws and institutions which have a respect to the sciences, to education, to police in the modern sense of that word, and to the various means of public defence and security. The design was not completed; no trace, at least, appears in the work published under the above title relative to the subjects of finance or public policy.[3] In estimating the value of these speculations, it is no less necessary than in the case of the former work, to consider them with a reference to the state of science at the time, rather than to the present extension of knowledge in this department. Under the first three divisions he enters at considerable length into some of the most interesting discussions which have arisen in this wide field; particularly as to the principles of public policy in regard to agriculture, to the commerce of grain, and foreign commerce generally, and to money and exchange.[4] In perspicuity of language, and distinct and patient illustration, the style of these discourses bears a considerable resemblance to that of the *Wealth of Nations;* but the coincidence between the two works, in some general and fundamental doctrines, is still more remarkable and interesting. Beccaria does not appear to have adopted the particular theory of the French economists, which was developed about that time; although his practical doctrines on some of the most important points were conformable to the conclusions deduced from that system.[5] Beccaria.

Among other inferences, to which the course of his reasoning leads him, as it were, by many different roads, may be noticed one, which he has himself ventured to state as a general proposition, and which marks the caution as well as enlargement of his mind in subjects of complicated inquiry. "Every restriction on freedom," he observes, "whether in the case of commerce or any other, ought to be a result from the necessity of preventing an actual disorder, not the effect of a purpose or aim at amelioration." And he has repeated the same doctrine under different views in various other passages.[6] On all these subjects he exercises, without ostentation, the privilege of examining and judging for himself; and in doing so, although he expresses himself with plainness and energy,[7] he is never dogmatical. He observes this further dictate of a sound philosophy,—to refrain as long as possible from any very general conclusions; and, although he appears to have disengaged his mind from the power of common and hereditary notions respecting political economy, he does not, by a transition too often made, substitute dangerous or extravagant positions in their place. He is even more distinguished by the temperate use which he makes of his liberty, than by the independence which secured him from the chain.

During the same period in which he pursued these labours, Beccaria undertook another literary task of a very different description, and commenced an *Inquiry into the Nature of Style*.[8] A first part of this *Inquiry* was published in 1770; but the author does not appear to have prosecuted his intention, and only one detached portion of the remainder was found among his papers.[9] The apology which he makes for this apparent deviation from his usual objects of pursuit, drawn from a consideration of the connection subsisting between the study of the fine arts, and that of moral and political science, affords a pleasing proof of the natural expansiveness of his mind.[10]

His scientific and literary studies were now to be interrupted, however, by new and more flattering marks of distinction from his government. By an imperial order of the 29th April 1771, he was appointed a member of the Supreme Economic Council; on the suppression of which, he was transferred to the magistracy of state; and, lastly, by a dispatch of the 17th January 1791, he was named one

---

[1] The originals of these dispatches are among the state papers in the public archives of Milan.

[2] The editor states that this publication was made from a copy of the discourses, transcribed for the author himself when he visited Paris in 1776.

[3] Some of the others, too, are treated rather briefly. He has himself defended this method of teaching by the following just and striking observations, in that part of the work where he discourses of *Interest:* "But woe to the teacher who would say all that is to be said, and leave nothing to the penetration of the learner. What is heard slips away and vanishes from the hearer's mind, unless he has an opportunity of opposing the re-action, as it were, of his own intellect, to the impressions of his instructor; and more light is thrown upon a science by one process of exact reasoning which we carry on for ourselves, and it is more deeply and firmly rooted in us by that single operation, than by many and repeated trains of reasoning conducted by another."

[4] Under the head of Agriculture, he proposes the scheme of an experimental farm to be carried on at the public expense, as a school of that science, and enters into some detail of its objects and regulations.

[5] Mirabeau's *Tableau Economique* had already appeared in the publication entitled *La Philosophie Rurale;* as well as various papers of Quesnay.

[6] For example, "The operations of Economics amount only to not permitting, and most frequently to letting alone."

[7] "Con un non fanatico vigore," as he has himself somewhere expressed it. But on occasions where he conceived that there might be a danger of inflaming the passions, he has claimed the tribute due to him for employing a style "beyond the reach of the uninformed and impatient multitude."

[8] *Ricerche intorno alla Natura dello Stile.*

[9] This additional chapter is given in the edition printed at Milan in 1809.

[10] In no part of his writings is the enlargement of his comprehension, as well as soundness of his judgment, more to be remarked, than in the *Treatise* on the State of Currency, which was his first publication, and written at the age of twenty-seven.

Beccaria. of the Board for Reform of the Judicial Code, civil and criminal. His activity and usefulness in the discharge of these great trusts are best proved by the circumstance, that some of the most important matters in those different departments were committed to his direction, and regulated by his counsels. The most remarkable of his state papers were, various *Ordinances* relative to the grain; a very important *Dispatch* transmitted to the Court in 1771, which gave rise to the reform of the public money in 1778; a *Plan* proposed in 1780 for effecting a uniformity in the weights and measures; and certain *Proposals*, in 1786, founded on the tables of the population. His writings of this description are characterized by method, perspicuity, and precision. It deserves to be particularly noticed respecting his scheme for the equalization of measures, that, of the different natural bases for exact measurement, he explicitly recommends that which may be obtained from the celestial bodies, and, in the application of it, proposes to employ the decimal method of division; being the same system which was afterwards adopted by the late government of France.[1]

In the year 1776 Beccaria made a journey to France, in company with his friend Alessandro Verri. He remained at Paris for about three weeks, which he passed chiefly in the society of D'Alembert and other eminent men of letters; and, on his return, he visited Voltaire. This journey seems to have been the only considerable incident which, during a period of twenty-five years, diversified his manner of life, or interrupted his official duties. He died of apoplexy, in the year 1793. According to the editor of his *Elementi*, in 1804, his death was unnoticed by his country, and his tomb remained without a name or an epitaph.

Beccaria was twice married. He was stedfast in his friendships; modest, but tenacious of his opinions. He took pleasure in the society of literary men, and avoided that of the great. It is related of him, that the king of Naples, while at Milan, twice attempted to visit him at his house; but that the marquis found means, on both occasions, to escape the honour intended for him by his majesty. His exertions in the service of the public, and, above all, his earnest endeavours to promote, by every means, the cause of science, and a liberal system of education, formed the chief feature of his life. On the latter topic he has made many forcible and eloquent appeals, in he course of his different writings; and some passages of this description, which are interspersed in his discourses of Political Economy, are not less to be admired for their intrinsic excellence, than they are interesting from the circumstances in which they were written, and the contrasts which they indirectly exhibit.

One trait of his constitutional disposition or confirmed habit has been recorded, as furnishing a remarkable exception to the general vigour of his intellectual character, —that, notwithstanding the force with which he combated the prejudices and unreasonable apprehensions of other men, he was himself subject, when left alone, to an unconquerable timidity. We are not told whether this tendency was ascribed to early habits and a faulty education, or supposed to be the consequence of some sudden and fatal impression, which remained indissolubly associated with certain outward circumstances, or in what other manner it was formed and perpetuated. On a superficial view, it seems to denote a mind radically weak. But this is not a necessary or a just inference. The fact is, indeed, singular, and deeply impressive; but, in truth, it only serves as a new example to prove how mixed is the nature of Beccaria. our frame; how imperfectly the understanding acts upon the will, and the will upon the moral part; and how many things appear to be within the jurisdiction of our reason, which, nevertheless, are superior to its control.

This is not the place to engage in a more particular examination of the spirit and scope of Beccaria's writings. He is said to have expressed, at least during the early part of his life, too unqualified an approbation of the works of Helvetius, and others belonging to the same school of philosophy. On this score some excuse may, perhaps, be found for him in the attractions which the style of the author now mentioned possesses for a youthful and ardent mind. It is to be observed, likewise, that, when he expressed this admiration of the productions alluded to, the *Système de la Nature* had not yet made its appearance. Nor is it to be supposed that he could be insensible to the notice and the applause of such men as then held the stations of greatest eminence in the scientific world. Yet whatever temptations he may have been exposed to from the influence of some of his literary associates, it is consolatory to reflect, that, neither in the works which he himself gave to the public, nor in those which have been brought to light since his death, are sentiments to be found which have a tendency to subvert any one foundation of private or of public good. His labours were beneficent, and their natural fruits the dissemination of useful knowledge, the increase of industry, and the improvement of social order. But he was not fated to witness the spectacle which ensued, or to be an observer of that moral crisis, of the results of which it may be questioned, if, hitherto, they have less disturbed the calculations of the friends of humanity, than baffled the counsels of its foes.

Some further information with respect to Beccaria's publications will be found in the *Notizie* prefixed to his *Economia Pubblica* (*Scrittori Classici Italiani*, tom. xi.); in the fourth volume of the *Biographie Universelle*, printed at Paris in 1811; and in the fourth and fifth volumes of the *Correspondence par le Baron de Grimm*. In the compilation first mentioned are contained (besides his *Elementi*) republications of his *Relazione della Riduzione delle Misure di lunghezza all' Uniformità, per lo stato di Milano;* of his *Prolusione letta nell' apertura della nuova cattedra de Scienze Camerali;* and of his inquiry *Del Disordine e De' Rimedi delle Monete*. In the same collection is likewise to be found a paper written by him for the periodical work called *Il Caffè;* viz. *Tentativo Analitico sui i Contrabbandi*, being an attempt to apply the algebraical method to certain subjects of political economy. A new edition of Morellet's French translation of the *Treatise on Crimes and Punishments* was published by M. Roederer in 1797; and a version of the same treatise in modern Greek, by Coray, was published at Paris in 1802. (J.G.D.)

Beccaria, *Giambattista*, a very ingenious and industrious electrician and practical astronomer, was born at Mondovi on the 2d of October 1716, and entered the religious order of the Pious Schools in 1732. He became a professor of experimental physics, first at Palermo, and then at Rome, and was appointed to the same situation at Turin in 1748: he was afterwards made tutor to the young princes de Chablais and de Carignan, and continued to reside principally at Turin during the remainder of his life. In May 1755 he was elected a fellow of the Royal Society of London, to which he afterwards communicated several papers relating to his favourite pursuits He died on the 27th of May 1781.

[1] In the mathematical calculations connected with this subject, he was assisted, as he himself states, by Frisi, Professor of Mathematics at Pisa; and in the mechanical part by his brother Annibale.

Beccaria. 1. The most voluminous and most important of his works, entitled *Dell' Elettrismo Artificiale e Naturali*, appeared at Turin, 1753, 4to, and was reprinted in 1772. It was translated into English, and published, with the original engravings, under the title of *A Treatise upon Artificial Electricity, and an Essay on the Mild and Slow Electricity of the Atmosphere.* Lond. 1771, 4to.

2. *Risposta ad una Lettera intorno al suo Elettrismo.* Milan, 1753, 4to.

3. *Lettere dell' Elettrismo Atmosferico. 2da, Ed.* 2. Turin, 1758, 4to.

4. *Experimenta et Observationes quibus Electricitas vindex late constituitur atque explicatur.* Graz. 4to.

The accurate and elaborate experiments related in these works obtained for their author the warm and repeated encomiums of the scientific historian Dr Priestley, and the approbation and friendship of other contemporary philosophers; although it must be confessed that, amidst the multitude of important facts recorded in them, we sometimes observe a want of clearness of arrangement and closeness of reasoning; nor must we attempt to claim for Beccaria either the originality of a Franklin, the mathematical precision of an Æpinus, the enlarged views of a Cavendish, or the neatness and inventive talent of a Volta. The most remarkable novelties which deserve to be distinguished among our author's experiments and opinions relate to the limited conducting power of water, to the electrification of the air and smoke, to the velocity of electricity, to the reduction of metals by its powers, to the illumination of the solar phosphori by the spark, to the light excited by the motion of the air, and to a variety of meteorological phenomena, especially lightning, storms, rain, water-spouts, and atmospherical magnetism. The resistance exhibited by water to the passage of the electric fluid is demonstrated by the luminous appearance of its path, while it passes through more perfect conductors without producing light, as well as by the explosion of glass tubes containing water, through which the spark is taken; and this experiment is extended to the construction of an electrical water-gun, which is said to have carried a small bullet with considerable force.

Father Beccaria observed, about the same time with Mr Canton, that the air surrounding an electrified body was capable of becoming electric by slow degrees, and that it also parted slowly with its electricity; and, by means of some property of this kind, he produced the appearance of a luminous atmosphere about an electrified ball, to which another was presented, in a partial vacuum. The smoke of colophony, surrounding an electrified body, enabled it to give longer sparks; but this smoke was little attracted by the body when the heated spoon containing the colophony was insulated. Respecting the velocity of electricity, he relates some experiments, which amply deserve to be confirmed or confuted. He found the effect of a spark occupy at least half a second in passing through 500 feet of wire, and six and a half through a hempen cord of the same length, although when the cord was wetted, it passed through it in two or three seconds. It is well known, that, in the earlier experiments of Watson, a shock was transmitted through a much longer circuit of wire, without occupying any perceptible interval of time in its passage. Many of the metals were revived from their oxyds, and mercury was reproduced from cinnabar by the powers of electricity; and our author fancied that he had discovered a common principle in the different metals, as several of them gave the same colour to the surface of the glass to which they were attached. The brilliancy of the electric light was demonstrated by the permanency of its effect on the solar phosphori; and this subject was afterwards pursued by various experiments of Canton and others. The light often exhibited by the air rushing into a vacuum is attributed by Beccaria to the friction of the air against the sides of the glass. It may be remarked that the phenomenon is, in all probability, of the same kind as the appearance of light observed long ago in the air-gun by its first inventor, Ctesibius of Alexandria. With respect to atmospherical electricity, Beccaria's researches were most laborious and extensive, and he made a great variety of experiments illustrative of the nature of lightning, and of storms in general; showing, for instance, the facility with which small bodies are forced into the course of the electric current, as light clouds are made to assist in conveying a stroke of lightning; and proving that evaporation, and the deposition of vapour, are always accompanied by electrical changes. Thunder-storms, in general, he attributes to terrestrial electricity, and supposes the clouds to be merely the channels by which the fluid is carried from one part of the earth's surface to another, the equilibrium having been first disturbed by chemical changes within the earth; and it must be confessed that this opinion is in some measure countenanced by the frequent connection which is observable between these phenomena and those of earthquakes and volcanic eruptions. Water-spouts, he assures us on the authority of several eye-witnesses, may certainly be dispersed by pointing swords and knives at them; and, with respect to conductors erected for safety, though he appreciates their utility very highly, he thinks that every large building should be furnished with more than one or two. The *electricitas vindex*, so often mentioned, is the electricity made sensible in one body by the removal of another which has been situated near it;—a property which afterwards led to the elegant inventions of the electrophorus and the condenser of Wilke and Volta. Our author appears to be somewhat disposed to exaggerate the importance of electrical changes as the causes of other atmospherical phenomena, and, in particular, to overrate the intimacy of the connection of electricity with magnetism. The appearance of the *aurora borealis* he attributes to the circulation of electricity through the higher regions of the atmosphere, and he was well aware of the magnetical changes which usually accompany this remarkable occurrence.

5. His papers in the *Philosophical Transactions* are all in Latin. The first is entitled *Experiments in Electricity, in a Letter to Dr Franklin.* (*Phil. Trans.* 1760, p. 514.) These experiments relate principally to the subject of electrical attractions and repulsions, which the author attempts to reduce to the effect of currents of air displaced by the immediate action of the electric fluid. He supposes the air between two bodies, in dissimilar states, to be rarefied by the interchange of their electricity, so as to produce the appearance of attraction; and when the bodies are in similar states, he imagines the air interposed to be the immediate object of their apparently mutual repulsion. The paper is accompanied by a note of Dr Franklin, explanatory of the apparatus employed.

6. *An Account of the Double Refractions in Crystals.* (*Phil. Trans.* 1762, p. 486.) The double refraction of rock crystal had been observed by Huygens. Beccaria seems to have imagined that it was not discoverable when the surfaces concerned were parallel to each other; but later observations have shown that his observations were defective in this respect, at the same time that they have confirmed his conjecture respecting the existence of a similar property in almost all crystallized substances.

7. *Novorum quorundam in re Electrica Experimentorum Specimen.* (*Phil. Trans.* 1766, p. 105.) In this paper our author defends the simpler theory of Franklin against Mr Symmer's doctrine of the existence of two separate elec-

Beccaria. tric fluids. He also enumerates a great variety of cases of the excitement of positive or negative electricity by the friction of different substances with glass, hare-skin, a silk stocking, sealing-wax, and sulphur.

8. A second paper, with the same title, appeared in the *Philosophical Transactions* for 1767, p. 297. It contains an account of a repetition of experiments on the modification produced in the charge of two or more glass plates, by separating them, and by removing and replacing their coatings. These investigations were principally suggested by the well-known observations of the Jesuits, made at Pekin many years before, and by some subsequent experiments of Mr Symmer. The author calls the effect an oscillation of electricity; it depends on the same causes as the "vindicating electricity," which he has elsewhere described.

9. *De Atmosphæra Electrica libellus.* (*Phil. Trans.* 1770, p. 277.) The phenomena of induced electricity are here discussed, but not with great precision: the author adverts, however, to the Newtonian demonstration of the equilibrium of the force of a gravitating substance, distributed through the surface of a sphere, with respect to a particle within it, and gives somewhat clearer views of the theory of electricity than his former works had exhibited, but still falls far short of the perfection which Æpinus had attained more than ten years before.

10. A short *Letter to Mr John Canton, on his new phosphorus receiving several colours, and only emitting the same,* is printed in the *Philosophical Transactions* for 1771, p. 212. Our author admitted the sun's light through green, red, and yellow glass, and found that the pieces of sulphureted lime exposed to it emitted only a light similar to that which had been thrown on them. A multiplicity of later experiments have however shown, that the contrary result is by far the most common; and Zanotti's earlier observations have been fully confirmed by Wilson, Grosser, and Seebeck.

11. In 1759 Beccaria received orders from his sovereign, in consequence of a suggestion of Boscovich, to measure the length of a degree of the meridian in the immediate neighbourhood of Turin: the measurement was completed in 1768, and an account of it was published under the title of *Gradus Taurinensis*, Turin, 1774, 4to; prefaced by a proper compliment to the memory of the monarch who patronized the undertaking, and to the virtues of his successors, under whose auspices it was completed. The result did not, however, exhibit the appearance of any great accuracy or good fortune; for there is not only a difference of one seventieth of the whole in the lengths of the degree computed from the northern and southern portions of the arc, of 27′ and 41′ respectively, but the length deduced from the whole arc, which is 57468·59 French toises, is 445 toises more than would be inferred from other measurements in the neighbouring latitudes; hence it appears to have been thought necessary by later astronomers to reject the northern portion altogether, and to make some corrections in the calculation from the southern, by which the length of the degree has been reduced to 57069 toises. The zenith sector employed for the observations was made on Boscovich's construction, the length of the tangent being measured instead of that of the arc, a method by no means calculated to lessen the chances of error. A portable syphon barometer is also described, by means of which the elevations were ascertained; and a number of heights of places in the mountains of Piedmont are recorded.

12. This volume appears to have been the last of Beccaria's publications: An *Essay on Storms and Tempests* is mentioned without approbation in the *Dictionnaire Historique*, but it was probably extracted from some of his other works. In his private history and adventures there appears to have been little for a biographer to relate: his ambition having been in a great measure limited, by the religious profession which he had adopted, to the acquirement of literary celebrity, his taste was guided by his prevailing pursuits. His only luxuries consisted in his library and instruments; and on these he expended a considerable part of the remuneration which he received for his services to the public and to his royal pupils. (T. Y.)

Beccles ‖ Beck.

BECCLES, a market-town and borough, county of Suffolk, hundred of Wangford, on the right bank of the river Waveney, 32 miles N.N.E. of Ipswich. It consists of several streets, is well built, and contains a fine old parish church, several dissenting places of worship, a free school founded in the reign of James I., a free grammar-school with ten exhibitions at Emanuel College, Cambridge, a handsome town-house, custom-house, &c. By means of the river, which is navigable to Yarmouth, a considerable trade in coals and groceries is carried on. Market-day Saturday. Pop. 1851, 4398.

BECERRA, Gaspard, an eminent Spanish fresco-painter and sculptor, born about the year 1520, at Bajeza, in Andalucia. He studied at Rome under Michael Angelo, and adorned with his paintings many churches in Spain. His chef-d'œuvre is a statue of the Virgin at Madrid, where he died in 1570.

BECHER, Johann Joachim, a celebrated chemist, born at Spires in 1635. He was connected with the most learned men in Europe; and the emperor, the electors of Mentz and Bavaria, and other persons of high rank, furnished him with the means of making experiments in natural philosophy, medicine, and chemistry. As his thoughts had been much directed to economical subjects, and particularly to the means of increasing the revenues of a state, he was invited to Vienna, where he contributed greatly to the establishment of several manufactures, a chamber of commerce, and an Indian company. But the jealousy of some of the ministers eventually occasioned his disgrace and ruin. Equally unfortunate at Mentz, Munich, and Wurzburg, he determined to repair to Haerlem, and here he invented a machine for working a great quantity of silk in a little time, and with few hands. But new misfortunes forced him to seek refuge in England, and he died at London in 1682. He wrote many works, the principal of which are, 1. *Physica Subterranea*, which was printed at Leipsic in 1703 and 1739, in octavo, with a small treatise, by E. Stahl, entitled *Specimen Becherianum;* 2. *Experimentum chymicum novum*, 8vo; 3. *Character pro Notitia Linguarum universali;* 4. *Institutiones Chymicæ, seu Manuductio ad Philosophiam Hermeticam*, 4to; 5. *Institutionis Chymicæ, seu Œdipus Chemicus*, 12mo; 6. *Experimentum novum ac curiosum de Miniaria arenaria perpetua*, &c.

BECK, or Beke (Saxon, *becc;* Dutch, *beck*), a word which imports a small stream of water issuing from some rill or spring. Hence *hellbecks*, little brooks in the rough and wild mountains about Richmond in Yorkshire, so called from their ghastliness and depth. Beck is also used in the composition of names of places originally situated on rivulets; hence Walbeck, Bournbeck, &c. The Germans use *beck* or *bach* in the same manner; as Lübeck, Griesbach.

Beck, or Beek, *David*, an eminent portrait-painter, born in 1621 at Arnheim in Guelderland. He became a disciple of Vandyk, from whom he acquired the fine manner of pencilling and sweet style of colouring peculiar to that great master and to all the disciples trained up under his direction. He possessed likewise that freedom of hand, and readiness or rather rapidity of execution, for which Vandyk was so remarkable; insomuch that when King Charles I. observed the expeditious manner of Beck's painting, he exclaimed, "Faith! Beck, I believe you could paint riding

Becket. post." He was appointed portrait-painter and chamberlain to Queen Christina of Sweden; and he executed portraits of most of the sovereigns of Europe to adorn her gallery. He lived in the highest favour with his royal mistress, and left the court of Sweden much against her inclination. He died soon after, at the Hague; and it was suspected that he had been poisoned. This happened in 1656, when Beck had only attained his thirty-fifth year. A very singular adventure happened to this artist as he travelled through Germany. Having been taken suddenly and violently ill at the inn where he lodged, he seemed to all appearance quite dead, and was laid out as a corpse. His valets expressed the strongest grief for the loss of their master, and while they sat beside his bed, drank very freely, by way of consoling themselves. At last one of them, getting much intoxicated, said to his companions, "Our master was fond of his glass while alive, and out of gratitude let us give him a glass now he is dead." The rest of the servants having assented to the proposal, he raised up the head of his master, and endeavoured to pour some of the liquor into his mouth. From the fragrance of the wine, or probably from the irritation produced by a small quantity getting down his throat, Beck revived and opened his eyes; when the drunken servant, forgetting that his master was considered as dead, compelled him to swallow the whole contents of the glass. The painter gradually recovered, and by proper care and management was soon restored to perfect health.

BECKET, Thomas À, lord chancellor of England, and archbishop of Canterbury, in the twelfth century. The story of his birth is as extraordinary as that of his life. It is related that his father Gilbert Becket, sometime sheriff of London, went on a pilgrimage to Jerusalem, where he was surprised and enslaved by a party of Saracens. His master's daughter fell in love with him, and when he made his escape, she followed him to London. So singular an instance of heroic affection made a deep impression on his mind; and, after consulting with some bishops, he had her baptized by the name of Matilda, and then married her. From this marriage sprung the haughty Thomas à Becket. Raised to the primacy, à Becket began the dispute between the crown and the tiara, and sided with the pope in the quarrel. At this King Henry II. was greatly offended; and convoking an assembly of the bishops at Westminster, offered six articles against papal encroachments, to which he urged à Becket to assent. Yielding to the importunities of several lords, à Becket signed the articles; but speedily relapsing into his former opinions he was ordered to be tried as a traitor; upon which he fled into Flanders. The king lost no time in banishing all his relations, and à Becket retaliated by excommunicating all his opponents. At last, after seven years spent in unavailing hostility, by the intercession of the French king and the pope he was allowed to return; but he peremptorily refused to absolve the bishops and others whom he had excommunicated; upon which the king, enraged at his obstinacy, exclaimed, "that he was an unhappy prince, who maintained a great number of lazy insignificant persons about him, none of whom had gratitude or spirit enough to revenge him on a single insolent prelate who gave him so much disturbance." The deadly hint was understood; and four gentlemen, or rather ruffians, of the court, immediately formed a design against the archbishop's life, which they executed in the cathedral church of Canterbury on the 29th of December 1171. Superstitiously afraid of polluting the sanctuary with blood, more especially with that of a mitred priest, they endeavoured to drag him out of the church; but finding they could not effect this without difficulty, they killed him at the altar. Afraid they had gone too far in violating the sanctity of the church, the assassins durst not return to the king's court at Normandy, but retired to Knaresborough in Yorkshire, where everybody avoided their company; scarcely any one, however low, deigning to eat or drink with them. Finding the curse of murder pursue them, they at length took a voyage to Rome, and being admitted to penance by Pope Alexander III. set out for Jerusalem, where, according to the pope's orders, they spent the remainder of their lives in penitential austerities. They died in the Black Mountain, and were buried at Jerusalem, outside the door of the church belonging to the Templars. King Henry affected to be much disturbed at the news of à Becket's death, and despatched an embassy to Rome to clear himself from the imputation of having caused or suggested it. The celebration of divine offices was discontinued in the church of Canterbury for a year, deducting nine days; at the end of which period it was reconsecrated by order of the pope. Two years after this à Becket was canonized; and Henry returning to England the ensuing year, went to Canterbury, where he did penance in testimony of his regret for the murder of à Becket. When he came within sight of the church where the archbishop lay buried, he alighted from his horse, and walked barefooted in the habit of a pilgrim till he came to à Becket's tomb, where, after he had prostrated himself and prayed for a considerable time, he submitted to be scourged by the monks, and passed all that day and night without any refreshment, kneeling upon the bare stones. In 1221, fifty years after the murder, à Becket's body was disinterred in the presence of King Henry III. and a great concourse of the nobility and others, and deposited in a rich shrine, erected at the expense of Stephen Langton, archbishop of Canterbury. It was soon visited from all parts, and enriched with the most costly gifts and offerings; and the miracles said to have been wrought at the tomb of the saint were so numerous that Gervase of Canterbury tells us two large volumes kept in the cathedral church were filled with accounts of them. The monks used to raise his body every year; and the day on which this annual resurrection was performed, called the "day of his translation," was kept as a general holiday. Every fiftieth year a jubilee was celebrated in his honour, which lasted fifteen days; plenary indulgences were then granted to all who visited his tomb; and 100,000 pilgrims were registered at a time in Canterbury. The worship of the saint in that city indeed had quite effaced the adoration of the Deity, nay, even that of the Virgin. At God's altar, for instance, there were offered in one year only L.3, 2s. 6d.; at the Virgin's L.63, 5s. 6d.; but at St Thomas's, L.832, 12s. 3d. And next year the disproportion was still greater; for at God's altar not a penny was offered; the Virgin's obtained only L.4, 1s. 8d.; while St Thomas got for his share L.954, 6s. 3d.;—a large sum, if the value of money in those times be considered, and a correspondingly strong proof of the hold which superstition then possessed over men's minds. Even Louis VII. of France made a pilgrimage to this miraculous tomb, and bestowed on the shrine a jewel which was esteemed the richest in Christendom. But Henry VIII., to whom a saint of so high character was naturally very obnoxious, not only pillaged the rich shrine dedicated to St Thomas, but caused the saint himself to be cited to appear in court, and to be tried and condemned as a traitor; at the same time ordering his name to be struck out of the calendar, the office for his festival to be expunged from all breviaries, and his bones to be burnt, and the ashes thrown in the air. À Becket was the subject of poetical legends; and *The Lives of the Saints* in verse, a manuscript which is supposed to belong to the fourteenth century, contains an account of his martyrdom and translation. We also learn from Peter de Blois that the palace of à Becket was perpetually filled with bishops highly accomplished in literature, who passed their time there in reading, disputing, and deciding important questions relating to the state. "These prelates, though men of the world, were a society of scholars; yet very different from those who frequented the universities, in which nothing was taught but words and syllables, un-

Becket.

Beckford || Beckmann.

profitable subtilties, elementary speculations, and trifling distinctions." De Blois was himself eminently learned, and one of the most distinguished ornaments of à Becket's household. John of Salisbury, his intimate friend, the companion of his exile, and the writer of his life, was scarcely exceeded by any man of his time for his knowledge in philological and polite literature. (See Dr Giles', *A Becket and His Times.*)

BECKFORD, WILLIAM, was the son of alderman Beckford, noted for his manly reply to George III. on the presentation of an address from the city of London. He was born in 1761, and at the age of nine he inherited an immense fortune from his father. In early life he travelled in Italy, Sicily, Spain, and Portugal, and resided some time in the latter kingdom, where he had a princely residence. He afterwards returned to England, and built a fine residence at Fonthill, on which he expended in about eighteen years the enormous sum of L.273,000. This, together with its splendid library and pictures, he sold to Mr Farquhar in 1822; but soon after, a tower of 260 feet fell down and buried part of the villa in the ruins. Mr Beckford afterwards began the erection of another lofty structure on Lansdownehill, near Bath, where he continued to reside till his death, which happened in 1844. He was a powerful and original writer. His first work, *Biographical Memoirs of Extraordinary Painters*, which appeared in 1780, exhibits much knowledge of the art. In 1784 he published in French the singular tale entitled *History of the Caliph Vathek*, which soon afterwards appeared in English. In 1834 his first Continental tour appeared under the title of *Letters from Italy, with Sketches of Spain and Portugal*, a work never perhaps surpassed for striking description and refined sarcasm. His latest production, published in 1835, was entitled *Recollections of an Excursion to Alcobaza and Batallia in* 1794. All these works exhibit uncommon power of vivid description, and a cultivated taste. He left two daughters, the eldest of whom was married to the late Duke of Hamilton.

BECKMANN, JOHANN, the author of the *History of Inventions*, was born at Hoya in the electorate of Hanover, in 1739. His father, who was receiver of taxes and postmaster in that town, occupied himself in the cultivation of a small piece of land, and appears to have inspired his son with a taste for agriculture. All the honour of his education belongs, however, to his mother, who, having become a widow when young Beckmann was scarcely seven years old, sent him, in his fifteenth year, to the school at Stade, placing him under the care of Gehlen. Being intended for the clerical function, he repaired in 1759 to Göttingen, to finish his studies there; but, whether the advice of Hollmann, who testified much kindness towards him, produced a change in his plans, or that the instructions of the mathematicians Kaestner and Tobias Mayer had greater attractions for him than theology, he abandoned the career on which he had entered, in order to devote himself entirely to the natural sciences, and principally to the application of these sciences to economical purposes. His first studies were not without their use to him; he derived from them a methodical habit of mind, and a considerable knowledge of languages, which, in the sequel, assisted him greatly in the pursuits to which he owed his celebrity. In 1762, having lost his mother, and with her his former means of subsistence, he accepted the offer of Busching, who invited him to come and fill the situation of professor of natural philosophy in the Lutheran Academy at St Petersburg, of which this celebrated geographer had at that time the direction; but Busching quitting the institution shortly after, and dissensions having arisen among the superintendents, Beckmann gave up his place, and made a journey through Sweden to acquire a detailed knowledge of the mines of that country, and of the manner of working them. Linnæus having received him hospitably at Upsal, he prolonged his stay there, and availed himself of the friendship as well as the instructions of that great naturalist. In 1766, the governors of the university of Göttingen appointed him, on the recommendation of Busching, professor to that celebrated establishment, of which he became one of the principal ornaments. His mind, entirely directed to the practical uses of human knowledge, had early conceived the idea of an academical classification of the arts and different branches of economy, both political and domestic, which had hitherto been left to routine and accident. He composed, to serve him as a guide in this course of instruction, *Treatises on Rural Economy, on Policy, on Finance, on Commerce*, and other departments of practical knowledge; which, though since carried to a higher degree of perfection, owed to Beckmann their primary elements and their first scientific form. His lectures, which had at the time the recommendation of novelty, were attended by the flower of the studious youth, whom the most civilized nations of Europe sent to the university of Göttingen; and it may be added, that the most distinguished statesmen and public functionaries of Germany were among his auditors. He was in the habit of accompanying them himself into the workshops, to give them a knowledge of the different processes and handicrafts of which he had explained to them the theory. He never relinquished his public lectures; but his private studies took insensibly a direction altogether historical, the motives for which it will not, perhaps, be uninteresting to point out.

Beckmann.

At Göttingen it is considered that a professor, in teaching a particular science, cannot be excused from explaining the progress of that science in all the civilized nations of Europe at the same time. Any one who, two years after the appearance of a work of importance in his department, published in any country of Europe, should not have read and analyzed it in orde. to refute or else enrich his own observations from it, would not regard himself as a worthy successor to the chair of Haller, of Mosheim, of Gesner, and Michaelis. Beckmann, in particular, having studied at Göttingen at a time when the example of these great men dictated the law and gave the tone there, was determined to advance in a line with his age, and not to be ignorant of any of the steps which were being made in the numerous and extensive sciences which furnished the foundation and the subjects of practical principles. But these steps were the steps of a giant; and whatever might be his ardour or his love of study, it was impossible to read and digest all the important works which appeared from the year 1770, on chemistry theoretical and practical, on physics, natural history, and mathematics. His disappointment ended in chagrin, and excited in him a degree of anger against the new ideas, methods of reasoning, and materials, which changed the face, enlarged the limits, and facilitated the study of these sciences. His course of lectures, turning only on practical matters, suffered little from this circumstance; but feeling that his writings would be open to the objection of being behind the advanced state of the sciences which were the subject of them, he directed the researches with which he wished to occupy the attention of the public to the history of arts and trades. He employed, in illustration of the subject, the materials to which he had access in the Göttingen library, assisted by general information, a mind peculiarly fitted for this kind of study, and indefatigable industry. It is to these labours that we owe the *Notices* of Beckmann on the History of Discoveries in the most common Arts of Life; for instance, the history of watch-making, of distillation, of almanacs, of insurance, of the lighting of streets, of the original country and migrations of the fruits and flowers in our gardens, of the common materials for dyeing, of bellows, of fire-arms, of mills, of grinding corn, of carriages, of different parts of our dress, of different household utensils, of a multitude of machines and mechanical contrivances employed in common trades; and of most of the products of industry, such as the gathering of saffron, the preparation of alum, the

Beckmann

printing-press, of fulling-mills, of book-keeping, of the digging of turf, of gazettes and newspapers, of stamped paper, of the pearl fishery, of pavings, of chimneys, of collections of natural curiosities, of mile-stones, of pharmacy, of quarantine, of painted paper, of ruffles, of milking, of pawnbrokers, of looking-glasses and glass in general, of soap, of musical glasses, of watchmen, of ices to be eaten, of the anatomy of plants, of exchange, of pens for writing, of instruments of husbandry, of fireworks, of the working of pewter, of the procuring of amber, of indigo, of the gilding of weather-cocks, of furs, of steel, of gardening, of crayons, of knives and forks, of corks, of sal-ammoniac, of hops, of weaving, of lotteries, of hospitals for orphans and foundlings, of infirmaries, of lazarettoes, of fighting-cocks, of saltpetre, of gunpowder, of aquafortis, &c. &c. We should form to ourselves a very false idea of these *Notices* if we expected to find in them only some general account of these arts, and of the different manner of practising them used in different times and places. Beckmann traces their first germ from the most remote periods of antiquity; he follows their development through the obscurity of the middle ages, and exhibits their latest improvements amongst the civilized nations of modern Europe, with a patience and a depth of learning which can only be equalled by the sagacity and the variety of knowledge displayed in his researches. We have thought it would be interesting to the reader to see a list of the most remarkable among these notices, in the order in which they were published. They make five volumes in octavo, published at Leipzig from 1783 to 1805, and furnish the most invaluable materials to the individual, or society of men of letters, who may hereafter venture to undertake the general history of the origin and progress of the mechanical arts, which are so important a branch in that of civilization. It is almost needless to add, that the most exact references to original authorities accompany each article, and give it a new value in the eyes of those who are unwilling to take things upon trust, or may be desirous to push still further the inquiries of the author. It has been translated into English.

The same merits belong to his *History of the earliest Voyages made in modern times;* a highly interesting collection, which occupied the last years of his life, and which he left at the eighth number. Another result of the literary application and industry of Beckmann was a return to the studies of humanity, to which we are indebted for editions of the work *De Mirabilibus Auscultationibus*, attributed to Aristotle (1786); of the *Wonderful Histories* of Antigonus Carystius (1791); and of Marbodius's *Treatise on Stones* (1799);—editions which required the rare union of physical knowledge and natural sagacity with philological learning. The Royal Society of Göttingen had, in the year 1772, admitted Beckmann among its members; and, from that period to 1783, he supplied their proceedings with interesting memoirs, among which are the following: *On the Reduction of Fossils to their Original Substances; On the History of Alum; On the Sap of Madder; On the Froth of the Sea, from which the Heads are formed for the Nicotian Fistulæ; On the History of Sugar.*[1] But from this period he withdrew from all further share in the labours of this learned body, probably from the same motives that we have assigned above for the change in the objects of his own particular studies. He was, besides, modest to an extreme degree; and his natural timidity did not find anything to counteract it in the traditional jealousy of reputation, which the example of his predecessors, who had founded the glory of Göttingen, had transmitted to a generation more confident of its powers, and more vain of its merit, but still restrained by habits difficult to lay aside, when the respect for great authorities had originally sanctioned them. His candour, his sincerity, his fidelity in friendship, his affability to his scholars, have been celebrated with one accord by his coadjutors and his auditors. Schlætzer, whom he had known from his youth in Russia, was the one among his colleagues with whom he maintained the most uninterrupted intimacy. He was better qualified than almost any one else to appreciate the researches of Beckmann, as he had himself insisted with so much force on the necessity of introducing into history a view of the influence exercised on social institutions by the efforts of industry, and by the birth or maturity of the most common arts. Beckmann died on the 3d of February 1811, after having been admitted into almost all the learned societies of Germany and the north, and after having impressed a tendency to pursuits of practical utility on the minds of a multitude of distinguished young men who had attended his lectures, and whom his celebrity drew to Göttingen during the forty-five years of his professorship. A portrait of him will be found at the head of the twelfth volume of the *Economical Encyclopædia* of Krunitz, and it has been engraved separately by Raid, Schwenterley, and Grape. Beckmann married the daughter of Hollmann, his tutor and friend; she survived him only a few weeks, and they left a son and daughter grown up. His eulogium was pronounced by his colleague, the illustrious Heyne, and was published at Göttingen with this title, *Memoria Joan. Beckmann, Soc. R. Sci. Götting. sodalis in concessu Soc. Publico D.* 16 *Febr.* 1811, *commendata.* (W. H–Z–T.)

Bectasse || Bed.

BECTASSE, or BEKTACHS, an order or set of religionists among the Turks, so called from their founder Bectach, preacher to Sultan Amurath. The habit of the Bectasse is white; and on their heads they wear white caps of several pieces, with turbans of wool twisted ropewise. They observe constantly the hour of prayer, which they perform in their own assemblies, and make frequent declarations of the unity of God.

BED, an article of furniture on which to stretch the body for sleep or repose. The modern bed is usually a sack or case of ticken, filled with feathers, chaff, wool, or other soft materials, placed upon a raised framework which is called the bedstead. In the first ages it was universally the practice for mankind to sleep upon skins of beasts. This was originally the custom of the Greeks and Romans, as also of the ancient Britons previous to the Roman invasion; and the skins thus employed were spread on the floor of their apartments. But they were afterwards changed for loose rushes and heath; and in process of time the Romans suggested to the central Britons the use, and the introduction of agriculture supplied them with the means, of the greater convenience of straw beds. The beds of the Roman patricians at this period were generally filled with feathers, and those of the inns with the soft down of reeds. But for many ages the beds of the Italians had been constantly composed of straw; it still formed those of the officers and soldiers present at the conquest of Lancashire; and from both, it is probable, our countrymen learnt the use of it. It appears, however, to have been used only by gentlemen, as the common Welsh had their beds thinly stuffed with rushes as late as the end of the twelfth century; and with the gentlemen it continued for many ages afterwards. Straw was used in the royal chambers of England as late as the close of the thirteenth century. Most of the peasants in different parts of the country sleep on chaff beds at present; in the Highlands heath is also very much employed as bedding; and in France and Italy straw beds remain in general use to this day.

Dining BED, *lectus triclíniaris* or *discubitorius*, that on which the ancients reclined at meals. The dining or discubitory beds were four or five feet in height. Three of these beds were ordinarily ranged by a square table (whence both the table and the apartment where it stood were called *tri-*

[1] See *Nov. Commentarii Soc. Sc. G.* tom. ii.-viii.; and *Commentar.* tom. i.-v.

Bed of Justice || Beddoes.

clinium), in such a manner that one of the sides of the table remained open and accessible to the waiters. See ACCUBATION.

Bed of Justice (*Lit de Justice*), in France, under the old régime, a throne upon which the king sat when he went to the parliament. The king never held a bed of justice unless for affairs that concerned the state, and then all the officers of parliament were clothed in scarlet robes. This ceremony in process of time became synonymous with an act of arbitrary power on the part of the sovereign. The last occasion on which a *lit de justice* was held, was on the 6th of August 1787, when the proposition for assembling the states-general was rejected.

BED-CHAMBER, *Lords of the*, officers of the royal household under the groom of the stole. They are twelve in number, and attend in turn, a week each. There are also thirteen grooms of the bed-chamber who wait by turn. Salaries are attached to these offices. A queen regnant in like manner is attended by *Ladies of the Bed-chamber*.

BEDA, commonly called *Venerable Bede*, one of our most ancient historians, was born about the year 673, in the neighbourhood of Wearmouth, in the bishopric of Durham. He was educated by the abbot Benedict, in the monastery of St Peter, near the mouth of the river Wear. He was ordained deacon at the age of nineteen, and priest at the age of thirty. About this time he was invited to Rome by Pope Sergius; but there is no good reason for believing that he accepted the invitation. In the year 731 he published his *Ecclesiastical History*; a work of great value, notwithstanding the legendary tales with which it is deformed. This work was first printed at Eslingen by Conrad Fyner in 1474, an edition extremely rare. Bede died in the year 735, of a lingering consumption, probably brought on by sedentary habits, and a long uninterrupted application to study and literary composition. He was buried in the church of his convent at Jarrow; but his bones were afterwards removed to Durham, and there deposited in the same coffin with those of St Cuthbert. Bede was undoubtedly a singular phenomenon in a rude and illiterate age. His learning, for the times, was extensive; his application incredible; his piety exemplary; and his modesty extreme. He was universally admired, consulted, and esteemed, during his life; and his writings are deservedly considered as the foundation of our ecclesiastical history. His language is neither elegant nor pure, but it is perspicuous and easy. All his works are in Latin. The first general collection of them appeared at Paris in 1544, in three volumes folio; and they were printed again at the same place in 1554, in eight volumes. They were also published in the same size and number of volumes at Basle in 1563, and reprinted at Cologne in 1612, and again in 1688. Besides this general collection, there are several of his compositions which have been printed separately, or in collections of the writings of ancient authors; and some manuscripts ascribed to him have been preserved in the different libraries of Oxford and Cambridge. A complete edition of the works of Bede, by Dr Giles, with an English translation of the historical treatises, was published at London in 1843–44, in 12 vols. 8vo.

BEDARRIÉUX, a town of France, department of Herault, on the Orbe, 18 miles north of Beziers. It is a neat, well-built town, and has very considerable manufactures of cloth, silk, hats, oil, paper, and soap, with dye-works and tanneries. Pop. (1846) 8722.

BEDDOES, THOMAS, a physician of equal eminence for his talents and philanthropy, was born at Shiffnall, in Shropshire, April 13. 1760. His family was of Welsh extraction. He received the first rudiments of his education at a school in his native town, and afterwards at a seminary at Brood, in Staffordshire. The strength of his intellectual powers was apparent at a very early period; and he was remarkable from his infancy for his insatiable thirst for books, and his indifference to those amusements which usually captivate the attention of children. His rising abilities were justly appreciated by his grandfather; and to this intelligent relative he was deeply indebted for many of the advantages of his early education, and for the decision of his father to educate him for one of the learned professions. When he was only nine years old, the circumstance of an accident which befell his benefactor, and which, after being followed by some remarkable symptoms, terminated fatally, was calculated to make a deep and lasting impression on a mind like that of young Beddoes. By the extraordinary acuteness and interest which he manifested on this occasion, he attracted the notice of Mr Yonge, the surgeon who attended the sufferer; and a foundation was thus laid for the friendship which ever after subsisted between them, and which appears to have had a considerable influence in his choice of that profession in which he was destined to run so brilliant a career. At the free grammar-school in Bridgenorth he made rapid progress in classical learning; and when about thirteen years of age, he was placed as a pupil with the Rev. Mr Dickenson, rector of Plymhill in Staffordshire, with whom he continued about two years. On quitting Mr Dickenson, he entered at Pembroke College, Oxford, in Michaelmas term 1776. The simplicity of his appearance, and the rusticity of his manners and address, could not long conceal the superiority of his mental powers. The themes and declamations of young Beddoes were remarkable for their elegant Latinity; and he soon acquired distinguished reputation as a classical scholar. Success in one acquisition was to him but an inducement to the possession of another. He was found one morning by a friend, who casually entered his apartment, very busily engaged with a French grammar and dictionary before him; and when his friend expressed his surprise that he should attempt to learn French without a master, he replied that he should be able to conquer the difficulties of the language by himself in about two months. His friend called upon him again at the expiration of that time, and inquired whether he had mastered the language. Beddoes answered in the affirmative, and proved his assertion by reading in English, with perfect fluency, a French book which the latter presented to him. From the French he proceeded to the Italian, which, from its analogy with the former, he acquired with greater ease. The German language presented more serious difficulties; but his perseverance triumphed over them without the aid of a master. He afterwards added the Spanish language to his other acquisitions.

Beddoes.

While attending the university, chemistry and the other sciences more closely connected with his future profession were always his favourite objects of pursuit. The splendid discoveries of Black and Priestley, which had opened a new field of discovery, were powerfully calculated to inflame the ardour of his inquisitive and sanguine spirit; and he accordingly soon became perfectly conversant with the new doctrines of pneumatic chemistry, and used to exhibit with great delight the experiments which supported them, to his friends in Shropshire, during the vacations. He was also much occupied with mineralogy and botany; and for the former of these sciences, especially, retained throughout life a remarkable fondness.

Having taken his bachelor's degree at one-and-twenty, he repaired to London, in order to commence the study of his profession. He became a pupil of the celebrated Sheldon, and devoted his time to the details of practical anatomy, and the physiological inquiries connected with it. It was while he was engaged in these studies that he gave to the world, in 1784, a translation from the Italian of Spallanzani's *Dissertations on Natural History*; a work which, in 1790, went through a second edition. In the year following, 1785, he published a translation of Bergman's *Essays on Elective Attractions*, the first work to which Beddoes affixed his name, accompanied by numerous original notes, which display an

Beddoes. accurate acquaintance with all the modern improvements in the physical sciences. In 1786 he became again known to the public as the editor of Scheele's *Chemical Essays*. Previous to this, in 1783, he took his degree of master of arts; and, in the autumn of 1784, removed to Edinburgh, where he remained during three successive winters and one summer. Shortly after his arrival, he became a member of the Medical Society and of the Natural History Society of that place, and took an active part in the series of physiological experiments in which some of the members of the former were at that period engaged. To the latter he contributed two papers, one on the *Sexual System of Linnæus*, the other on the *Scale of Being*, both of which have been preserved at full length in Dr Stock's memoirs of his life. At Edinburgh not only did he receive every mark of honourable distinction from his fellow-students which it was in their power to confer, but was also chosen as the organ of their remonstrances with the managers of the Infirmary, on the occasion of a misunderstanding which had arisen between them as to the hours at which they should be permitted to attend; and they were eminently indebted to him for the firmness with which he on that occasion maintained their privileges.

He took his degree of doctor of medicine at Oxford, in December 1786; and in the ensuing summer he visited the Highlands, and also spent a short time at Paris and Dijon, where he cultivated the acquaintance of Lavoisier and Guyton de Morveau. Soon afterwards he was appointed to succeed Dr Austin in the chemical lectureship at Oxford. The success which attended his exertions to inspire a taste for scientific researches was soon apparent, in the overflowing audience attracted by his lectures. Enjoying the reputation of distinguished talents, and surrounded by men of learning and abilities who courted his society, his situation at the university appears to have been truly enviable; and it is difficult to understand the motives which could have led him to relinquish all these advantages for the uncertain prospects afforded by his establishing himself in any other place. The decided part which he took in the political discussions that were agitated at the beginning of the French revolution, seems to have had a principal share in this determination. His opinions were on this occasion expressed with his usual freedom; and the circulation of a political article which he inserted in a Shropshire paper, in an advertisement soliciting relief for the French emigrant clergy, excited a clamour against him, which accelerated his adoption of the step he had previously determined upon.

During his connection with Oxford, he published, in 1790, an analytical account of the writings of Mayow, under the title of *Chemical Experiments and Opinions, extracted from a work published in the last century*, in which he asserts the claims of that extraordinary man to the discovery of the principal facts on which the modern system of pneumatic chemistry is founded; discoveries which had failed, for upwards of a century, to attract any notice from the philosophic world. In the *Philosophical Transactions* for 1791 and 1792 we also find three papers by Dr Beddoes; the one containing *Observations on the Affinity between Basaltes and Granite*, in which he rejects the common division of mountains into primary and secondary, and states some strong arguments in favour of the volcanic origin of both; the other giving *An Account of some Appearances attending the Conversion of Cast into Malleable Iron*, which he supposes to consist in its purification from oxygen, charcoal, and hydrogen, which escape, during the process, in the form of carbonic acid and carburetted hydrogen gases; and, in a paper which forms an appendix to the latter, he relates a variety of experiments which he had made, confirming this theory.

It was about the period of his retirement from Oxford that he published his *Observations on the Nature of Demonstrative Evidence, with an Explanation of Certain Difficulties occurring in the Elements of Geometry, and Reflections on Language*, 8vo, London, 1793. In this essay Beddoes. he contends, in opposition to the doctrines of the ontologists, and particularly to that of Mr Harris, the author of *Hermes*, that geometry is essentially founded in experiment; and that mathematical reasoning proceeds, at every step, upon the evidence of the senses; in short, that this science is founded as exclusively upon the induction of particular facts, as mechanics, astronomy, optics, or chemistry.

About the same period he published his *Observations on the Nature and Cure of Calculus, Sea-Scurvy, Consumption, Catarrh, and Fever; together with Conjectures upon several other Objects of Physiology and Pathology*.

On leaving Oxford, he retired to the house of his friend Mr Reynolds of Ketley, in Shropshire. It was here that he published his admirable *History of Isaac Jenkins*, a story exhibiting the reformation of a drunkard, and his return to habits of industry. There is, probably, no production of Dr Beddoes which unites so many peculiar excellencies as this inimitable fiction, or which displays at once in so favourable a light the vigour of his genius, his knowledge of the human heart, and the power with which he could command the interest and sympathy of his reader. Its success was immense; repeated editions, amounting to above forty thousand copies, were rapidly sold; and a large impression has since been issued at the request of a society for promoting knowledge by the distribution of useful popular books.

A prospect now opened to him of realizing his favourite scheme of establishing a pneumatic institution, where the medical efficacy of the permanently elastic fluids, the fruits of the modern improvements in chemistry, could be fairly put to the test of experiment; and, after some deliberation, the neighbourhood of Bristol was fixed upon as the most proper place for the purpose. In making the necessary arrangements, he derived material assistance from the co-operation of Mr Edgeworth, the author of *Practical Education*, with whose family he soon became more closely connected, by marrying one of that gentleman's daughters. The pneumatic institution continued to occupy his attention for many years, in the course of which a great number of publications issued from his pen, illustrating the principles on which he expected it to be useful, and detailing the experiments and the results to which it gave rise. The difficulty at first experienced in the construction and management of the apparatus of this institution, was in no long time entirely surmounted by the friendly assistance of Mr Watt, whose exertions at this critical period are acknowledged in a dedication prefixed to the first part of the *Considerations*. Mr William Clayfield and Mr Read also contributed their assistance in the invention of different parts of the pneumatic apparatus. At the opening of the institution in 1798, the sums subscribed were found to be very inadequate to the purposes for which it was designed; but by the liberality of Mr Thomas Wedgewood, who offered Dr Beddoes L.1000, he was enabled to carry the plan into immediate execution. All that was now wanted was to procure a superintendent; and he had the good fortune to engage in that capacity a young man who had already given proofs of extraordinary talents, and to whose penetrating genius chemistry has since been so deeply indebted. There needs no other indication to suggest the name of Davy,—a name that will descend to distant ages as associated with so many important discoveries in philosophical science. The history of the pneumatic institution indeed derives considerable splendour from many of these discoveries, which were perfected in its laboratory, and which were first announced to the world through the medium of the publications above mentioned; and in the work entitled *Researches Chemical and Philosophical, chiefly concerning Nitrous Oxide, or Dephlogisticated Nitrous Air, and its Respiration*; by Humphrey Davy, Superintendent of the Medical Pneumatic Institution,

London, 1800. The discovery of the chemical properties of this gas, and of its astonishing effect on the system when respired, were among the first, and must ever be esteemed the most brilliant, of the results of this institution: it raised the most sanguine anticipations in the mind of Dr Beddoes, and called forth all his eloquence in the description of what it already had and might be expected to accomplish. These, like the other splendid visions in which his ardent imagination was but too prone to indulge, have never been realized, and have even created, by their signal failure, an unfortunate prejudice against future attempts to improve the art of medicine by novel methods of treatment founded on chemical or philosophical principles. The original objects of the institution, being found unattainable, were successively abandoned; and it assumed, by insensible gradations, the form of the more common establishments for the relief of the sick; and the prevention rather than the cure of diseases became the principal aim of its conductors. In 1807 it was finally relinquished by Dr Beddoes to the care of Mr King and Dr Stock.

The object which Dr Beddoes had ever most at heart was, to excite a lively and general attention to the means of preserving health, and of repelling the first inroads of disease, by the diffusion of medical knowledge throughout all ranks of the community, as far as they were capable of acquiring it. His attention was uniformly directed to this favourite object, and he suffered no opportunity to escape of enforcing those maxims which tend to prevent the necessity of the interference of his art.

Dr Beddoes has been very justly characterized as a pioneer in the road to discovery. He was more active, however, in exciting the labours of others, than in labouring himself in the field of experiment. He had the imagination of a poet, and could paint in the most vivid colours the sufferings entailed by disease, and enforce with the most powerful eloquence whatever he wished to impress on the minds of his readers. He has been accused of versatility of opinion; but if he was, perhaps, hasty in publishing the first conceptions which he formed, he has atoned for this fault by the remarkable candour with which he retracted them the moment his confidence in them was shaken. Besides his numerous medical works, he was also the author of several political publications which appeared in 1795, 1796, 1797. (Stock's *Memoirs of Dr Beddoes*, Lond. 1811. (P. M. R.)

BEDE. See BEDA.

BEDELL, DR WILLIAM, a learned prelate, born in Essex in 1570. He accompanied Sir Henry Wotton, the English ambassador to Venice, in 1604, and spent eight years in that city, where he contracted an intimate acquaintance with the celebrated Father Paul. Of him Bedell learned enough of Italian to be able to translate the English Common Prayer Book into that language; and in return he drew up an English grammar for Father Paul, who declared that he had learned more from Bedell in all parts of divinity than from any other person. In 1629, he obtained the bishopric of Kilmore and Ardagh in Ireland, and finding these dioceses in very great disorder, applied himself vigorously to the reform of abuses. He procured an Irish translation of the Common Prayer Book, which he caused to be read in his cathedral every Sunday; and the New Testament having been translated by Archbishop Daniel, he caused a version of the Old Testament to be made, which was afterwards printed at the expense of the Honourable Robert Boyle. In 1624, he published a controversial book against the Roman Catholics; and he assisted the archbishop of Spalatro in finishing his famous work *De Republica Ecclesiastica*. When the rebellion broke out in Ireland in October 1641, the bishop's was the only house in the county of Cavan that remained inviolate. About the middle of December, however, the rebels, pursuant to orders received from their council of state at Kilkenny, required him to dismiss the people who had fled to him for protection; but he peremptorily refused to do so. Upon this the bishop and his family were carried prisoners to the castle of Cloughboughter; but after a confinement of about three weeks, the prisoners were exchanged for some of the principal rebels. The bishop, however, died soon after, Feb. 7. 1642, and the chiefs of the rebels honoured his memory by accompanying his remains to the tomb.

BEDFORD, the county town of Bedfordshire, is a municipal and parliamentary borough and market-town, situated in a fertile vale on both sides of the river Ouse, which is here crossed by a handsome stone bridge of five arches. It is 50 miles N.W. of London by road, and 62¾ by the North-Western Railway, a branch of which goes off from the main line at Bletchley to Bedford. The town consists chiefly of one long wide street, intersected by smaller ones at right angles, and is well built, paved, and lighted with gas. It has five parish churches, four of which are fine old Gothic edifices: the fifth is a recent erection in the Norman style. A district church was opened in 1841. There are also Independent, Methodist, and Baptist chapels, and a small Jewish synagogue. Bedford in proportion to its size has more public endowments than any other place in the kingdom, for which it is chiefly indebted to Sir W. Harper, Lord Mayor of London in 1561, who founded here a free school, and conveyed for its support, and for portioning poor maidens, a piece of ground in London, the overplus, if any, to be given to the poor. This ground has gradually risen in value so as now to produce nearly L.14,000 annually. It supports a grammar and other schools, and 58 almshouses, besides large sums given annually as marriage portions, for apprenticing youths, and other benevolent purposes. In 1849 above L.4000 were expended on the schools, L.1750 on the almshouses, L.858 in apprentice fees, L.400 in marriage portions, L.179 in donations to servants, and upwards of L.1000 in other charities. The grammar-school has eight exhibitions of L.80 per annum each, at Oxford, Cambridge, or Dublin. Among its public buildings are the county hall, the jail, built on the site of that in which Bunyan wrote his *Pilgrim's Progress*—house of correction, lunatic asylum, infirmary, Bedford library and subscription rooms, and the corn exchange. Its principal manufactures are straw-plait and lace; and a considerable trade is carried on with Lynn Regis, by means of the Ouse, in corn, malt, coals, timber, and iron. Market-days, for cattle, Monday, and for corn, Saturday. Bedford is governed by a mayor, 6 aldermen, and 18 councillors; and it sends two members to parliament. Pop. 1851, 11,693.

BEDFORD LEVEL, the name given to a flat district on the eastern coast of England, comprising the greater part (amounting to 450,000 acres) of the marshy district called the *Fens*, the whole isle of Ely in Cambridgeshire, and a portion of the south of that county, 30,000 acres of Suffolk, 63,000 acres of Norfolk, 57,000 of Huntingdon, about 8000 of Northamptonshire, and the south-eastern portion of Lincolnshire. The extent of the whole tract is 60 miles in length, from Milton in Cambridge to Toynton in Lincoln; its breadth is about 40 miles, from Peterborough in Northampton to Brandon in Suffolk. The boundary on three sides is of an irregular form, giving it something of a horse-shoe shape, with the opening terminated by the sea on the north.

This district obtained its present name from the agreement of Francis Earl of Bedford, the principal landholder, and thirteen other adventurers, with Charles I. in 1634, to drain the level, on condition of receiving 95,000 acres of the reclaimed land. This district has within historic periods undergone remarkable changes. In the time of the Romans it was a dense forest, which, as a stronghold of the Britons, those invaders destroyed. It then became a swamp, through which the lazy waters of the Ouse, the Welland, the Nene, and Wisbeach, crept to the sea. In the thirteenth century, the sea here, as in other parts of N.W. Europe, burst its

Bedford. boundaries, and the inundated land became a pestilential swamp. The first attempt to drain this morass seems to have been made in the year 1436, and embankments and ditches were formed at a great expense. These, however, were swept away during the ensuing winter by the flooding of the river Ouse. Another partial attempt at drainage was made by Bishop Moreton in the reign of Henry VII., but this also proved a failure. An act was passed in the 44th year of Queen Elizabeth for effecting its reclamation; but the first effectual attempt at reclaiming it was not made until 1634, as already mentioned; and many embankments and canals were constructed at various intervals at an expense above one million sterling. Three years after the agreement of the Earl of Bedford and his partners with the king, after an outlay of L.100,000 on the part of the company, the contract was annulled, on the fraudulent plea that the works were insufficient; and an offer was made by King Charles to undertake its completion on condition of receiving 57,000 acres in addition to the amount originally agreed on. This unjust attempt was frustrated by the breaking out of the civil war; and no further attempt at drainage was made till 1649, when the parliament reinstated the Earl of Bedford's successor in his father's rights. After an additional outlay of L.300,000, the adventurers received 95,000 acres of reclaimed land, according to the contract, which however fell far short of repaying the expense of the undertaking. In 1664 a royal charter was obtained to incorporate the company, which still exists, and carries on the concern under a governor, 6 bailiffs, 20 conservators, and a commonalty, each of whom must possess 100 acres of land in the level, and has a voice in the election of officers. The conservators must each possess not less than 280 acres, the governor and bailiffs each 400 acres. The original adventurers had allotments of land according to their interest of the original 95,000 acres; but Charles II., on granting the charter, took care to secure to the crown a lot of 12,000 acres out of the 95,000, which, however, is held under the directors, whereas the allotments are not held in common, though subject to the laws of the corporation. The level was divided in 1697 into three parts, called the North, Middle, and South Levels, comprising respectively the tracts between the Welland and the Nene, the Nene and Old Bedford rivers, and the third between Old Bedford river and the southern limit of the level.

Since then extensive works have at different times been carried on to complete the drainage of this district; but the most effectual are under the Acts of 1827 and 1829, for "improving the outfall of the Nene," "The Navigation of the Wisbeach," and "The Embanking of the Salt Marshes between the canal called Kinderley Cut and the sea." Vessels of 60 tons burden can now come up to the town of Wisbeach at all tides, and those of from 100 to 200 tons at spring tides. The draining of the lower lands, which, like the Dutch *Polders*, are below low-water mark, was carried on by windmills; but these have now been almost superseded by steam-engines, with great advantage: in the North Level the drainage is effected by sluices without either windmills or steam-engines. As the result of these extensive operations, the level now abounds in rich pasture and corn lands. (Moore, Dodson, and Burrell, on the Bedford Level; *Parliamentary Papers*, 1827–29.)

Bedford, *New*, a seaport town of North America, state of Massachusetts, near the entrance of Buzzard's Bay, 51 miles S.S.E. of Boston, with which it is connected by railway. The city is built on a commanding elevation above the west bank of the Acushnet river, and presents a very handsome appearance. The principal public buildings are the town-hall, custom-house, court-house, and several churches. This city is mainly indebted for its prosperity to the whale fishery, to which it furnishes no less than two-thirds of the whole shipping so employed by the United States. Besides oil and candles, it has large manufactures of cordage, hoops, &c. The ship-building also is very considerable. Pop. (1850) 16,464. Bedfordshire.

BEDFORDSHIRE, an inland English county, situated nearly in the centre of the island, but rather towards the eastern side. It is bounded on the north by Huntingdonshire and Northamptonshire, on the west by Buckingham shire, on the south by that county and Herefordshire, and on the east by the latter and Cambridgeshire. Its greatest length is about thirty-six miles, and its greatest breadth twenty-one miles. Its extent is 295,582 English statute acres, or nearly 462 square miles.

The face of the country is in general level, but with gentle undulations, scarcely deserving the name of hills, except towards Buckinghamshire, from which county a part of the Chiltern range enters, but only the lowest portion of that range. The chalk of these hills is found to be a valuable manure on some of the other soils of the county. From the S.E. to the centre of the county is a valuable district of dairy land. The western side is chiefly a sandy soil, but, being well cultivated on the Norfolk system, is productive; near Woburn it is generally sandy, and was sterile till the modern improvements in agriculture, fostered by the late Duke of Bedford, had extended their influence and productiveness. Near Biggleswade is a portion of land which yields the highest rent and most valuable products. It is cultivated by a class of market gardeners, and onion and other seeds are grown there for the supply of the shops of the seedsmen in London. Much of the former barren sandy soils has been planted of late years, and the inclosure of many of the largest common fields has improved both the beauty and the fertility of the county.

The land is drained by many brooks, which contribute to increase the rivers, and, by rendering them navigable, minister to the benefit of the inhabitants. No county is better accommodated with good roads than Bedfordshire, chiefly owing to the exertions of the late Mr Whitbread, before whose time they were in a very bad condition. The river Ouse enters this county on its north-western side, collects the water from a considerable district during a winding course, and becomes navigable at Bedford. In its progress towards Huntingdonshire it receives the waters of the Ivel, which is also navigable as high up as Shefford, and the united streams run to the German Ocean at Lynn. A small portion of the western side of the county is benefited by its water communication with London, and with the coal districts of Staffordshire, which it enjoys through the Grand Junction Canal.

As Bedfordshire is mainly an agricultural county, and as nearly four-fifths of the land are devoted to pasture or to the dairy, and little more than one-fifth is under tillage, the increased number of inhabitants has caused a scarcity of employment, and a consequent great advance in the poor rates. The present Duke of Bedford, the largest landowner in the county, has done much for the amelioration of his tenantry, by draining and otherwise improving their lands, erecting comfortable dwellings, establishing schools, and other means. The farms are let at valuation, the duke selecting his tenant from the various applicants. The chief occupation of the manufacturing kind consists in plaiting straw and forming it into chip hats, making baskets and other articles; and is confined almost exclusively to females. Dunstable has long been celebrated for this trade, and it is considerably extended over other parts of the county. Besides this, till of late years, the trade of bone lace, made both from silk and thread, afforded employment to the females, and still continues to do so in an inferior degree, though it has been much diminished by the introduction and improvements in machine lace. Some trade is carried on by the rivers and canal, by which corn and butter are conveyed to distant markets, and the inhabitants supplied with fuel. As the great north roads pass through the county in two lines,

Bedfordshire.

the traffic on these gives some activity to its commerce. Branches of the North-Western railway go to Bedford and Dunstable, and the Great Northern railway passes through the eastern part of the county.

The civil division of the county is into nine hundreds, which contain nine market-towns and 124 parishes. In an ecclesiastical view it forms part of the diocese of Ely and the archdeanery of Bedford; in its judicial relation it is in the Norfolk circuit.

The titles derived from the county are that of duke to the house of Russell, and of baron of Bletsoe to the family of Lord St John. Two members of the House of Commons are returned by the county, and two by the town of Bedford, the only borough within it.

The most distinguished residences in this county are, 1*st*, Woburn Abbey, near the town of that name. It was formerly a Cistercian abbey, granted at the Reformation by Henry VIII. to the family of Russell, the fourth duke of which house erected the present edifice. It is a very grand and capacious pile, situated in an extensive park, and is furnished with a large and valuable collection of paintings and statues. The collection of agricultural and arboricultural plants grown here is well deserving the notice of the student. 2*dly*, Luton Hoo, a mansion which was reconstructed and improved for John Earl of Bute by Adam the architect. A library, 146 feet in length, furnished with a valuable collection of books, and a large selection of paintings of some of the first masters, chiefly of the Italian school, are its distinguishing ornaments. The grounds have received every improvement that art can produce in a situation not naturally picturesque. 3*dly*, Ampthill Park, formerly the seat of the Earls of Upper Ossory, now of Lord Holland. This superb edifice, which contains a good library, a valuable collection of paintings, and a museum of natural history, stands in a delightful park, adorned with most beautiful spreading ancient oaks.

Besides these there are other mansions which are highly deserving of notice and admiration, especially that of Mr Whitbread at South-hill; Wrest Park, belonging to the Countess de Grey; Hawnes House, to Lord Carteret; Moggenhanger House, to Mr Thornton; Potten, to Sir John Burgoyne; Oakley House, to the Marquis of Tavistock; Old Warden Park to Lord Ongley; and, though not so distinguished by its extent as many others, Cardington House, once the residence of Howard the philanthropist, now of Mr S. C. Whitbread.

The population of the county stood at the three last decennial numerations as follows:—

Year.	Males.	Females.	Total.	Houses.
1831,	46,450	49,033	95,483	18,473
1841,	52,190	55,746	107,936	21,964
1851,	59,941	64,537	124,478	25,461

In the year 1841 the number of persons living by trade, commerce, &c., was 14,333; by agriculture 14,933: 19,923 were labourers, servants, &c. The towns and their populations in 1851 were as follow:—Bedford, 11,693; Biggleswade, 3976; Dunstable, 3589; Leighton-Buzzard, 4465; Luton, 10,648.

When the Romans landed in this kingdom Bedfordshire formed a portion of a district called Catieuchlana, whose sovereign or chief, Cassibelenus or Cassibelaunus, commanded the united forces which opposed Julius Cæsar. When, in the year 310, the Emperor Constantine ruled the whole island, and divided it into five provinces, Bedfordshire was included in the third division called *Flavia Cæsariensis*, and remained so till the final abandonment of Britain by the Romans. Under the Saxon heptarchy it formed part of the kingdom of Mercia, until with the rest of the island it was united to the kingdom of the West Saxons, which was divided by Alfred into counties, hundreds, and tythings; when this county first received the name it has since retained.

Bedlam ‖ Bedworth.

There are many remains of Roman, Saxon, and Norman antiquities. Traces of a Roman station are to be seen at Sandys near Potton, and at Maiden-Bower near Dunstable. Leighton-Buzzard, or Beaudesart, is supposed to have been a Roman camp; and vestiges of a Roman amphitheatre may be seen near Bradford Magna. The ancient Icknield and Watling Street roads passed through the county, and the remains of each may be definitely traced, as well as of some others constructed by the Romans. (W.J.)

BEDLAM, a house for lunatics. The word is a corruption of *Bethlehem*, the name of a religious house in London which was converted into an hospital for the insane.

BEDLOE, William, better known by his assumed title of *Captain*, was an infamous adventurer of low birth, who had travelled, under various disguises, over a great part of Europe. Encouraged by the success of Titus Oates, he turned general evidence, gave an account of Godfrey's murder, and added many circumstances to the narrative of Oates. A reward of L.500 was voted to Bedloe by the commons; and he is said to have asserted the reality of the Papist plot on his deathbed; but the whole story is overlaid with absurdity, contradiction, and perjury. Bedloe died in 1680. Giles Jacob states, that he was author of a play entitled *The Excommunicated Prince, or the False Relict*, 1679; but Anthony Wood asserts, that it was written by one Thomas Walter, M.A. of Jesus College, Oxford.

BEDNORE, a town of Hindustan, in the territories of the rajah of Mysore. In 1645 the seat of government of the rajahs of Ikeri was transferred to this place; and as the inhabitants of the former capital removed with the court, Bednore became a city of great importance, containing, it is said, 20,000 houses, besides huts. It was taken and plundered by Hyder in 1763, who ordered it to be called Hydernagur. It is still however known by its original name of Bednore. At that time it was estimated at eight miles in circumference. In 1783 it surrendered to a British detachment under General Matthews, but being shortly after invested by Tippoo Sultan, the garrison capitulated on condition of safe conduct to the coast. Tippoo violated the stipulation, put General Matthews and the principal officers to death, and imprisoned the remainder of the force. At Tippoo's death it contained 1500 houses, besides huts. Distance N.W. from Seringapatam 150 miles. Lat. 13. 50. Long. 75. 6.

The district of Bednore is situated on the summit of that range of hills, the Western Ghauts, which overlooks the provinces of Canara and Malabar. In consequence of its elevation above the sea, and the steepness of the mountain chain, which rises like a wall to the height of 4000 or 5000 feet, the clouds of the south-west monsoon are here intercepted, and their contents precipitated on the table-land in deluges of rain, which continue for six months in the year, and are extremely favourable to vegetation. Its products are pepper, betel-nut, cardamums, and sandal-wood. Cattle of small size are also bred in the district. The imports are salt, rice, cocoa-nuts, oil, turmeric and cotton cloths. (E.T.)

BEDOUINS, or Bedouis, a modern name of the wild Arabs, whether in Asia or Africa. See Arabia.

BEDRIACUM, a village of Cisalpine Gaul, situated between Verona and Cremona. From the account given by Tacitus, Cluverius conjectures that the ancient Bedriacum stood in the place where the city of Canneto now stands. Here the army of the Emperor Otho was defeated A.D. 69, by the united forces of Cæcina and Valens, generals of Vitellius. A few months later the Vitellian forces were defeated at the same place by Antonius Primus, the lieutenant of Vespasian.

BEDWORTH, a town and parish of Warwickshire, 3½ miles south of Nuneaton. Area 2157 acres. Pop. of pa-

Bedwyn || Bee.

rish (1851) 5059; of town, 3012, chiefly employed in the manufacture of ribbons, of bricks, and malt. In the vicinity are extensive coal-pits and stone-quarries.

BEDWYN, GREAT, a borough, market-town, and parish in the county of Wilts, 70 miles from London. on the Kennet and Avon Canal. It is a place of great antiquity, and, till the Reform bill passed, returned two members to parliament. It has little trade; and the only building that merits attention is the church, which contains several very ancient monuments. Pop. of parish in 1851, 2193.

Bedwyn || Bee.

BEE.

Progress of knowledge regarding this insect.

THE bee, from its singular instincts, its active industry, and the useful products resulting from its labours, has, from the remotest times, attracted the attention, not only of naturalists, but of mankind in general. No nation upon earth has had so many historians as this remarkable tribe of insects. The patience and sagacity of the naturalist have had an ample field for exercise in the study of their structure, physiology, and domestic economy. Their preservation and increase have been objects of assiduous care to the agriculturist; and their reputed perfection of policy and government have long been the theme of admiration, and have afforded copious materials for argument and allusion to the poet and the moralist in every age. It is a subject that has been celebrated and adorned by the muse of Virgil, as well as illustrated by the philosophic genius of Aristotle. Cicero and Pliny report that Aristomachus devoted himself during sixty years to the study of these insects; and Philiscus is said to have retired into a desert wood, that he might pursue his observations on them without interruption. A prodigious number of authors have written express treatises on bees; periodical works have been published relating exclusively to their management and economy; and learned societies have been established for the sole purpose of conducting researches on this subject. The most celebrated association of this kind is the *Société des Abeilles*, founded about fifty years ago in Little Bautzen, a village in Upper Lausatia, under the auspices of the elector of Saxony. Its labours, as we shall presently find, have enriched the science with a number of valuable discoveries.

In so complicated a branch of natural history, the application of the difficult art of observing correctly, and of the cautious processes of induction, cannot be effected without laborious and long-continued efforts. But, on the subject of bees, the inquirer after truth had, besides, many obstacles to encounter, from the very general diffusion of errors, which had been transmitted without due examination from one author to another. The history of the opinions of successive writers will sufficiently prove how gradual and how slow has been the advancement of real knowledge in what concerns these insects, and will teach us to estimate the value of that which we at length possess, as being the result of the labour of ages, and as being extorted from nature by indefatigable and persevering exertions. So great an accumulation of curious and interesting facts, indeed, has accrued to us from the researches of Swammerdam, Maraldi, Reaumur, Schirach, and Huber, as to constitute almost a new science. Many of these have been discovered subsequently to the time of the compilation of the article BEE in the preceding edition of this work. It will therefore be proper, in this place, to give a connected and systematic account of the natural history of this remarkable insect. For the details of the external characters and distinctions of species, we shall refer to the article ENTOMOLOGY. The principal features of their internal conformation will be described when treating of the particular functions to which they are more immediately subservient; and our descriptions will apply, more especially, to the common and best-known species, the *Apis mellifica*, which is the one particularly prized on account of the rich products it affords.

Plan of this article.

The economy of bees comprehends so wide a field of inquiry, the different parts of which are so connected and dependent upon one another, that it is impossible to treat of them distinctly, without supposing the reader to possess some general acquaintance with the history of these insects. We shall therefore premise a brief account of the different sorts of bees inhabiting the hive, and of the respective offices of each. We shall then proceed to consider their comparative physiology; under which head we shall state the leading particulars relating to their nutrition, secretion, respiration, progressive motion, external senses, and instincts. We shall next follow them in their different labours, from the period when the swarm has settled in a new habitation; we shall detail the complex structure of their hives,—their curious processes of architecture,—the pains they bestow on rearing their progeny, and in sending forth new swarms; and this will lead us to the subject of the fecundation of the queens, and the massacre of the drones. After having thus given an account of their usual condition, we shall, in the last place, describe the result of several experiments and observations which have been made when they were placed in unusual circumstances; experiments which have exhibited many interesting features of their character, and have thrown considerable light on the whole of their history, as well as suggested various practical and economic applications in the management of these insects.

Functions of the males, females, and neuters.

The leading feature in their history, and one which distinguishes them from almost all insects, is their singular distribution into three different kinds, constituting, to all appearance, so many different modifications of sex. The drone, which is characterized by a thicker body, a round head, a more flattened shape, and more obtusely-terminated abdomen, within which are contained the male organs of generation, has been admitted as the male of the species. It is distinguished also by the absence of a sting, and by the humming noise that accompanies its flight. The queen-bee, which is larger than any of the others, has the abdomen of greater length, and is provided with a sting, and with two ovaria of considerable size, is unequivocally recognised as the female. The working bees compose the third class, and are distinguished by the smallness of their size, their lengthened proboscis, the peculiar structure of their legs and thighs, which are adapted to the collection of certain materials obtained from vegetables, and by the apparent absence of every trace of generative organs,—we say apparent absence, because, as will be hereafter stated, rudiments of ovaria have been very lately discovered to exist, which, however, are not perceptible without a very minute and careful dissection. Till within a few years the working bees were regarded as animals deprived of sex, and were accordingly termed *neuters* or *mules*. It is these which perform all the laborious offices for the community,—which construct the interior of their habitation,—which explore the country in search of nourishment and other materials,—which collect and bring them to the hive, and apply them to different purposes; it is this kind that assiduously attend upon the queen, and supply all her wants,—that defend the hive from the attacks of depredators, and carry on hostilities against the various enemies of the tribe. The life of the

Bee.

females is chiefly engrossed with the duties of laying eggs, and conducting the colonies, which, at certain periods, emigrate from the parent state. The drones, producing neither wax nor honey, and depending on the rest for their subsistence, are idle spectators of these labours. They appear to be formed only for the momentary but important duty of impregnation, since they perish when this purpose is accomplished. There is commonly only one perfect queen existing at a time within each hive; and she appears to be treated by all the other bees with every mark of affection and of deference. The number of labourers is very different in different hives; sometimes there are only a few thousands; at other times from twenty to forty, or even fifty thousand. The drones, even in the spring, seldom compose more than one thirtieth or one fortieth of the whole; and, at other seasons, there are none to be found in the hive. In order to form some estimate of the number of bees which can occupy a certain space, Mr Hunter counted what number of drowned bees could be contained in an alehouse pint, and found it to be 2160; so that if a swarm were to fill two quarts, their numbers would be nearly 9000. Reaumur, with the same view of ascertaining their numbers, employed the more accurate method of weighing them; he found that a collection of them, weighing one ounce, consisted of 336 bees; and, therefore, that 16 ounces, or one pound, would consist of 5376 bees.

Real sex of the working bees.

Notwithstanding these differences in conformation, instincts, and offices, between the queen-bee and the workers, it is now established, upon the most incontrovertible evidence, that they both originally proceed from the same kind of larva, and that the queen-bee lays only two kinds of eggs, the one destined to produce the drone, the others capable of being converted, according to circumstances, either into a worker or a queen. It has been proved that the former, although exhibiting no appearance of sexual organs on a superficial examination, are in reality females, and have the rudiments of these organs, which, from their not being developed, are incapable of exercising their proper functions. It may be remarked, that the idea of the working bees being radically females, had been suggested long ago by Dr Warder, in his *Monarchy of Bees*, in which he terms them "True Amazons;" but no attention had been paid to his opinion. The real merit of this great discovery, which affords the key to a multitude of hitherto inexplicable facts, unquestionably belongs to Mr Schirach, vicar of Little Bautzen, the secretary of the Lausatian Society, to which we formerly adverted. When first announced to the world, it was received with suspicion by the greater number of naturalists, and with complete incredulity by others. It was, indeed, at variance with the whole tenor of the observations of Swammerdam, Maraldi, and Reaumur. Wilhelmi, the brother-in-law of Schirach, though an eye-witness of the experiments from which he had deduced this theory, for a long time refused to admit the doctrine, but became at length one of its most strenuous supporters. It is noticed in a vein of sarcastic ridicule by Mr John Hunter, in his otherwise excellent paper on bees in the *Philosophical Transactions*. Needham wrote a memoir for the Imperial Academy of Brussels in 1777, for the express purpose of refuting it; and he then inveighs in strong language against those naturalists who had deigned to give it the least countenance. Mr Key, in the *Bath Society Papers*, declares that he made experiments on this subject for eight years, without obtaining a single result in conformity to Schirach's views. Bonnet, after exercising a laudable scepticism, and making a diligent inquiry, in which he displays a genuine spirit of philosophy, yielded a reluctant assent. But the truth of the doctrine has since been placed beyond the reach of controversy by multiplied series of observations and experiments in different parts of Europe; and more especially by the recent investigations of Mr Huber of Geneva. We shall not at present enter into the detail of proofs, because their force will be better appreciated when other particulars belonging to the history of the bee have been explained.

Bee.

In considering the physiology of the bee, the first function that claims our notice is that of nutrition. The food of bees is principally of two kinds, namely, the fluid secretions of vegetables contained in the nectarea of the flowers, and the dust of the antheræ, which has been termed by botanists the pollen, but which, when collected by the bees, has received a variety of appellations, such as farina, bee-bread, raw wax (*cire brute*), &c. Occasionally, however, we find bees feeding upon other saccharine substances besides honey, such as honey-dew, treacle, syrup, &c.

Nutrition.

The organs by which they collect food are extremely complex, for they comprise instruments adapted to the reception of liquid aliment as well as those fitted for the division of solid materials. Reaumur has given the most elaborate description of these organs, in which he has corrected some errors that Swammerdam had fallen into. For the purpose of taking up fluids, they are provided, in common with all hymenopterous insects, with a long and flexible proboscis or trunk, which may be considered as a lengthened tongue, though, strictly speaking, it is formed by a prolongation of the under lip. It is not tubular, as Swammerdam had supposed, but solid throughout; and the minute depression at its extremity is not the aperture of any canal through which liquids can be absorbed. Cuvier, in his *Leçons d'Anatomie Comparée*, has not marked this distinguishing feature in the proboscis of the bee, but speaks of it in common with the tubular trunks of the other hymenoptera, and describes its aperture as being situated in the lower part. But Reaumur has very satisfactorily shown that the trunk of the bee performs strictly the office of a tongue, and not that of a tube for suction; for when it takes up honey or other fluid aliment, the under or the upper surfaces are more immediately applied to it, and rolled from side to side, and the bee thus licks up what adheres to it, while the extremity of the trunk is frequently not applied at all to the substance taken up. The trunk is supported on a pedicle, which admits of being bent back or propelled forwards, and thus can retract or stretch out the trunk to a considerable extent. Protection is given to it by a double sheath; the external, consisting of two scales furnished by the expansion of one of the portions of the labial palpi; and the internal, formed by the prolongation of the two external portions of the jaw. The whole member thus consists of five principal parts, on which account Fabricius termed it *lingua quinquefida*.

Organs for collecting food.

Proboscis.

For the purpose of mechanically dividing solid materials, the mouth is furnished with two strong mandibles and four palpi; they are but little employed in eating, but are of great use in enabling the insect to seize and break down hard substances for other purposes. In the working bee all these parts are of larger dimensions than in the other kinds. The teeth are two in number, and have the form of concave scales with sharp edges; they are fixed to the ends of the jaws, and play horizontally as in other insects. Reaumur describes and delineates a large aperture above the root of the proboscis, which is so surrounded with fleshy parts as not to be readily seen unless the proboscis be extended and bent downwards. This he considers as the mouth or orifice of the gullet; on the upper side of which, and of course opposite to the root of the proboscis, a small fleshy and pointed organ is seen, which he regards as the tongue, assisting in the deglutition of the

Mandibles.

Bee. food. Through this orifice, it is presumed, all the aliment, whether liquid or solid, passes; the former being conveyed to it by the trunk, which, by its contractile power, presses forward the fluids it has collected between itself and the inner sheath, and the latter being received directly after its comminution by the teeth, behind which it is situated. Latreille, however, whose authority is great on a point of this nature, thinks that Reaumur has deceived himself with regard to such an aperture, and disbelieves its existence. He conceives that the food simply passes on by the sides of the tongue, finding its way from thence into the œsophagus, and so on to the stomach.

Stomachs. The bee has two stomachs; the first is a large transparent membranous bag, pointed in front, and swelling out into two pouches behind. It performs an office in some respects analogous to that of the crop in birds; for it receives and retains for a time the fluid of the nectarea, which does not appear to differ in any respect from honey. Mr Hunter observes, that, whatever time the contents of this reservoir may be retained, he never found them altered, so as to give the idea of digestion having taken place. The coats of this reservoir are muscular, by which means it is capable of throwing up the honey into the mouth, so that it is regurgitated into the honey cells, or imparted to other bees. None of it ever passes out from the extremity of the trunk, as Swammerdam had believed. For the purpose of digestion, a second stomach is provided, which takes its origin from the middle of the two posterior lobes of the former, and is of a lengthened cylindrical shape. Its communication with the intestine is not direct, but takes place by a projecting or inverted pylorus, thickest at its most prominent part, with a very small opening in the centre, of a peculiar construction. This inward projecting part is easily seen through the coats of the reservoir, especially if full of honey. A similar kind of structure takes place at the communication of the first with the second stomach, and, having the properties of a valve, must effectually prevent all regurgitation from the latter into the former.

Collection of pollen. The pollen of flowers, which is the other principal article of food, was shown by Swammerdam to consist of an infinite number of small particles, generally of a globular shape, each of which is found to be a small capsule, inclosing the still finer dust or fecundating principle destined to be shed on the pistils for the purpose of germination. Geoffroy has given a memoir, published in the *Collection Académique des Sciences*, containing a minute description of the shapes of these capsules, taken from different flowers. The working bees, by means of the pencil of hair which grows on the tarsi, first collect a certain quantity of pollen, which they knead together into a ball, and place it in the concave space which is situated at the middle joint of the hinder feet, and has been termed the basket. The surrounding rows of hairs keep the ball from falling off. In order to gather larger quantities at once, the bees are sometimes observed to roll their bodies on the flower, and then, brushing off the pollen which adheres to them with their feet, form it into two masses, which they dispose of as before mentioned; and it is said that, in moist weather, when the particles of pollen cannot be readily made to cohere together, they return to their hive dusted all over with pollen, which they then brush off with their feet. They are often obliged to tear open the capsules which contain the pollen, in order to procure a supply of this substance, when it has not yet been shed by the flowers.

Pollen is yielded by flowers during the spring in such abundance that the bees of a single hive will often bring back one pound, or even more, in a day. Some agriculturists have accordingly imagined, that the vegetation of some plants might be endangered from this great consumption of the fecundating principle by insects in general; for other insects besides bees seek it with avidity. But this fear has been proved to be totally without foundation, and the practice of destroying bees in order to prevent this imaginary danger is therefore as useless as it is barbarous. It would appear, indeed, that so far from obstructing the fecundation of plants, the labours of the bee have often tended materially to promote it, by the agitation which they give to the flower, and by transporting the pollen from one flower to another. In this manner may we account for the number of hybrid flowers that are met with near the haunts of bees. Bee.

It has been shown very clearly by Huber, in a paper in the *Journal de Physique*, that pollen is peculiarly the food of the young bees, and is collected by the working bees with this intention. Reaumur, however, asserts that he has seen adult bees devour pollen. Swammerdam, who conceived the trunk to be tubular, rejected the idea that pollen could ever be the food of bees, as the globules of which it consists are incapable of entering an orifice so minute as that which appears at the extremity of the trunk, and which, as he was unacquainted with the real mouth, he thought was the only passage to the stomach. Latreille, who does not admit the existence of the large mouth described by Reaumur, states that the mandibles lay hold of the pollen, and carry it to the base of the trunk, from whence it finds its way into the œsophagus by the sides of that organ.

Of honey-dew, which forms part of the food of bees, we shall merely remark that it is an excrementitious matter deposited on the leaves of plants by certain species of aphides.

An abundant supply of water is essential to the healthy condition of bees. They consume a large quantity, and often stop to drink at the edge of stagnant pools, and seem even to prefer putrid and urinous waters to purer streams, as if their saline and pungent qualities were grateful to them.

Production of wax. It has been long the opinion that wax was but a slight modification of pollen, which required for this conversion merely the application of a certain pressure, and a kind of kneading by the feet of the bees. Many naturalists, such as Bernard de Jussieu, had persuaded themselves that the dust of the stamina of flowers contained wax ready formed as one of its ingredients, and quoted the following experiment in proof of this opinion: If the minute grains of pollen be put into water, they gradually swell, till they at length burst, at which moment a small jet of an oily liquor will be perceived, which floats on the water without mixing with it. But Reaumur had attempted in vain to extract any thing like wax from dust of the anthers; and, indeed, an attention to the chemical properties of these two substances would have sufficiently pointed out their essential differences. From the upper surface of the leaves of many kinds of trees, a substance has indeed been obtained, which possesses all the qualities of bees' wax; but nothing like it can be extracted from pollen. Reaumur was persuaded that the pollen was elaborated in the second stomach of the bee, and thrown up into the mouth in the form of a white foam, which, by exposure to the air, hardened, and became wax; and that the bee took advantage of its soft state to apply it in the building of the combs. So circumstantial an account, given to us by a scrupulous observer of facts, appeared to be perfectly satisfactory, and was acquiesced in by naturalists in general. But it has since been completely proved by the researches of Duchet, of Hunter, and of Huber, but principally by the latter, that wax is a secretion from the abdomen of the bee; and that it depends not at all

Bee. on the pollen which the insect may consume, but on the quantity of honey or other saccharine substance which it receives into the stomach. The first step in this discovery was made by one of the members of the Lausatian Society, whose name has not been preserved. It was mentioned in a letter of Mr Wilhelmi to Bonnet, in August 1768, in which he says that wax, instead of being rejected by the mouth, exudes from the rings which inclose the posterior part of the body. Of this we may satisfy ourselves by drawing out the bee from the cell in which it is working with wax, by means of the point of a fine needle; and we may perceive, in proportion as the body is elongated, that the wax will make its appearance under the rings, in the form of small scales. Mr Duchet, in his *Culture des Abeilles*, gives a full statement of the principal circumstances attending the production of wax, which he very justly ascribes to the conversion of honey into this substance in the body of the bee. These facts appear to have been entirely overlooked till the subject was again brought forward by Mr John Hunter, in his paper in the *Philosophical Transactions* for 1792. Wildman, however, had cursorily remarked that portions of wax, in the form of scales, and which he conceived must have been moulded on the body of the bee, are sometimes found at the bottom of the hive. Mr Huber was engaged in prosecuting his inquiries on this subject at the same period with Mr Hunter, and discovered, in 1793, the existence of regular receptacles or pouches, from the coats of which the wax is secreted, and within which it accumulates till its edges raise the scales, and become apparent externally. These plates of wax are withdrawn by the bee itself, or some of its fellow-labourers, and are applied in a manner hereafter to be described.

Huber has shown, by a series of well-conducted experiments, that, in a natural state, the quantity of wax secreted is in proportion to the consumption of honey; but that an equal or even greater quantity will be formed if the bee be fed on a solution of sugar in water. Warmth and rest promote this process of secretion; for the bees, after feeding plentifully on saccharine food, hang together in a cluster without moving, for several hours, at the end of which time large plates of wax are found under the abdominal rings. This happened when bees were confined and restricted from any other sort of nourishment; whilst those that were fed on pollen and fruits alone did not produce any wax. It appears also from his researches that the formation of wax is the office of a particular set of bees, which may be distinguished from the rest, and particularly from those that nurse the young larvæ, by the greater size and more cylindrical shape of their abdomen. Dissection also shows that their stomachs are more capacious. In the second volume of Huber's *Nouvelles Observations sur les Abeilles*, he describes minutely the anatomy of the pouches or receptacles for the wax, which are parts peculiar to the working bees, being totally absent in the males and queens. It is a structure that had escaped the keen eyes of Swammerdam, and has not been noticed by any subsequent anatomist. The cavities are lined with a membrane, which presents a number of folds, forming an hexagonal net-work, not unlike the appearance in the second stomach of ruminant quadrupeds, and evidently destined to perform the office of secretion.

Among the secretions peculiar to the bee, the poison which is poured into the wounds made by the sting deserves to be noticed. It is said to owe its mischievous efficacy to certain pungent salts. If a bee is provoked to strike its sting against a plate of glass, a drop of poison will be discharged; and if this is placed under a microscope, the salts may be seen to concrete, as the liquor dries, into clear, oblong, pointed crystals. The sting consists of bearded darts, which are protruded from the end of a sheath; and the venomous juice is likewise injected through the sheath, from a little bag at the root of the sting. Bee.

As no organs for the circulation of blood have been yet demonstrated in insects, respiration is supposed to be effected by means totally different from those which are adopted in the higher classes of the animal kingdom. As the blood, or fluid corresponding to the blood, cannot be presented to the air in any separate organ, the air must be conducted to the blood, wherever such a fluid is met with. For this purpose, tracheæ or air-tubes, having several external openings or spiracles, are made to ramify like arteries, and are distributed in an infinite number of branches to every part of the body. The analogy of other insects might perhaps be admitted as sufficient evidence that bees respire atmospheric air, the constant renewal of which is essentially necessary to the continuance of the vital functions. It is, however, not always safe to trust to analogical reasoning in subjects of natural history; and direct evidence is, in all cases, to be preferred when it can be obtained. We must therefore consider as valuable the complete series of experiments on the respiration of bees, that have been lately given to the world by Huber, to whom we already owe so large a portion of the information we possess with regard to these insects. We might indeed have anticipated, with the strongest probability, many of the results to which these experiments have led; but there are others which are quite unexpected, and possess as much of interest as of novelty. Function of respiration.

The condition of a hive of bees, in which many thousand individuals, full of animation and activity, are crowded together in the very small space of one or two cubic feet, having no communication with the external air but by means of a small aperture in the lowest part, which entrance is frequently obstructed by a throng of bees that are passing in and out during sultry weather, is of all possible conditions the one least favourable to the renewal of heated air. The most crowded theatres or hospitals are not to be compared with it in point of closeness. Direct experiment, indeed, shows that the combustion of a taper could not be carried on in so limited a space; for Mr Huber found that, in a glass ball of the same dimensions as the hive, and with a similar aperture, the taper went out in a few minutes. So great was the difficulty of explaining the respiration of bees under these circumstances, that Mr Huber was led to examine into the truth of the opinion, that respiration was equally necessary to bees as to other insects. The results were unequivocal. They perish speedily in the vacuum of the air-pump. They are easily drowned by placing them so that the spiracles on the corslet are under water; but revive readily when they are dried. The action of the spiracles is, in this experiment, rendered manifest by the escape of bubbles of air from each of their orifices. When a number of bees are confined in a bottle accurately closed, they exhibit unequivocal symptoms of distress, and fall into complete asphyxia. These changes occur more rapidly when they are placed in any gas which contains no admixture of oxygen, such as carbonic acid, hydrogenous and azotic gases. When they are rendered torpid by cold, and respiration is thereby suspended, these effects do not take place. All these effects are more considerable in adult bees than in the larvæ, though they are also distinctly exhibited in the latter. Suffocation is retarded if the proportion of oxygen be greater than in atmospheric air, and it may be averted altogether by a continual renewal of oxygen. It was ascertained by the eudiometer that the same changes were produced on the air as in the respiration of other animals; namely, the subtraction of Its necessity.

Bee. oxygen and the addition of an equal volume of carbonic acid gas.

Yet, on examining the air of the hive itself, it was found scarcely to differ in purity from atmospheric air. It was at one time conjectured that some of the contents of the hive, such as the pollen, the honey, or the wax, might have some power of evolving oxygen, so as to afford the requisite supply of this gas. Experiments, however, proved that they had no such power. Amidst so great an uncertainty, it was thought worth while to ascertain whether bees might not exert some unknown process by which oxygen was generated in the hive itself. If this were true, they could support life although all communication with the external air were intercepted. A hive was selected having glass sides, so as to allow of the observer's seeing what was passing in the interior, and the entrance was completely closed. In a quarter of an hour the bees became sensible of their situation, and showed great uneasiness; all business was suspended; an extraordinary agitation, accompanied by a remarkable noise, prevailed in every quarter. All the bees were seen beating their wings with the same rapidity as in flying. They were thus incessantly occupied during ten minutes. Their motions became then more languid, and, after being utterly exhausted, they fell in succession to the bottom of the hive, till every one of them was in a state of complete asphyxia. It is remarkable that, at this period, the temperature of the hive, which had been previously at 95° of Fahrenheit, suddenly cooled down to that of the external air. On opening the door and the top of the hive, and establishing a current of air through it, the bees were soon restored to animation.

Their mode of ventilating the hive. It was proved by this experiment that the air is renewed through the small opening which serves as a door to the hive. By suspending light substances near the entrance, the existence of different currents of air was rendered manifest. After much reflection, it occurred that the violent agitation of the wings might have some influence in procuring this renewal of air. This conjecture was confirmed by an experiment with a glass bell, to the aperture of which an apparatus was fitted, consisting of a small ventilator, which could be moved rapidly round by machinery. When the ventilator was set in motion, the air within could support the combustion of a candle for an unlimited time. Observation further showed that some bees are actually always employed in the office of ventilating the hive; they vibrate their wings with great vigour and constancy, producing so rapid a movement of them, that they cannot be seen except in the two extremities of the arc of vibration, which is at least one of 90°. While thus imitating the actions of flying, they fasten themselves with their feet to the floor of the hive, so that the whole effect of that impulse which, were they at liberty, would carry them forwards with considerable velocity, is exerted on the air, which is therefore driven backwards in a powerful current. Some bees occasionally perform these ventilating motions on the outside of the hive, near the entrance; but a still greater number are employed in this office within doors: sometimes twenty are thus occupied at once, and each bee continues its motions for a certain time, occasionally for nearly half an hour, and is then relieved by another, who takes its place. This is the occasion of that humming sound which is constantly heard from the interior of the hive when the bees are not in a state of torpidity. But it is often heard with even more than usual loudness in the depth of winter. The warmth of the sun's rays, however, always occasions an increased activity among the ventilating bees. The immediate cause of these actions is probably some impression made on their organs by the presence of vitiated air; for a bee may be made to ventilate itself by placing near it substances which have to them an unpleasant odour, such as spirit of wine or oil of turpentine. Bee.

Temperature of the hive. The connection between an active respiration and a high temperature is remarkably exemplified in bees, among which, in consequence of their collecting together in large numbers, the heat is not so easily dissipated, and admits also of being easily ascertained by the thermometer. Mr Hunter found it to vary from 73° to 84° of Fahrenheit; and Mr Huber observed it on some occasions to rise suddenly from about 92° to above 104°.

Progressive motion. Bees are well fitted, by their structure, for rapid flight through the air. They possess great muscular strength in proportion to their size, and their indefatigable activity in the different labours of the hive is truly astonishing. Aristotle and Pliny have pretended that, during high winds, they endeavour to steady their flight by holding a small stone with their feet, by way of ballast. This assertion has been shown, both by Swammerdam and Reaumur, to be erroneous in as far as it applied to the common bee; but there are other species which build nests with stones and other hard materials, and which, while transporting them for this purpose, were probably mistaken for the honey-bee.

Sensitive powers. The physiology of the external senses must necessarily be very imperfectly understood in a class of animals of a nature so remote from our own species. The infinite diversity of characters presented to us by the different tribes of insects, as well as of other animals, naturally suggests the idea that external objects produce on their sentient organs impressions widely different from what they communicate to ourselves. The notions we form of their senses must not only be liable to great inaccuracy, but must often be totally inadequate representations of the truth. A finer organization, and more subtle perceptions, would alone suffice to extend the sphere of their ordinary senses to an inconceivable degree, as the telescope and the microscope have with us extended the powers of vision. But they possess, in all probability, other organs, appropriated to unknown kinds of impressions, and which must open to them avenues to knowledge of various kinds, to which we must ever remain total strangers. Art has with us supplied many elaborate modes of bringing within our cognizance some of the properties of matter which nature has not immediately furnished us with the means of detecting. But who will compare our thermometers, electroscopes, or hygrometers, however elaborately constructed, with those refined instruments with which the lower classes, and particularly insects, appear to be so liberally provided? The antennæ, which are so universally met with in this class of animals, are doubtless organs of the greatest importance in conveying impressions from without. Their continual motion, the constant use which is made of them in examining objects, the total derangement in the instincts of those insects which have been deprived of them, point them out as exquisite organs of more than one sense. To impressions of touch, arising from the immediate contact of bodies, they are highly sensible; but their motions evidently show that they are affected by objects at some distance. They are no doubt alive to all the tremulous motions of the surrounding air, and probably communicate perceptions of some of its other qualities. Composed of a great number of articulations, they are exceedingly flexible in every direction, and can readily embrace the outline of any body that the bee wishes to examine, however small its diameter, and are capable of following all its movements. It is by means of these instruments that the bee is enabled to execute so many works in the interior of the hive, from which the light must be totally exclud-

Functions of the antennæ.

Bee.

ed. Aided by these, it builds its combs, pours honey into its magazines, feeds the larvæ, and ministers to every want, which it discovers and judges of solely by this species of touch.

The antennæ appear also to be the principal means employed for mutual communication of impressions. The different modes of contact constitute a sort of language, which appears to be susceptible of a great variety of modifications, and to be capable of supplying at once every species of information for which they have occasion. It is in this way alone that they satisfy themselves of the presence of their queen, or communicate to others the alarming intelligence that she has disappeared.

Vision.

The sense residing in the antennæ appears to be, on many occasions, supplementary to that of vision, which in bees, as in other insects, is less perfect than in the larger animals. During the night, therefore, they are chiefly guided in their movements by the former of these senses. This will sufficiently appear from observing by moon-light the mode in which the bees guard the entrance of the hive against the intrusion of moths which flutter in the neighbourhood. They act as vigilant sentinels, performing continual rounds near this important post, extending their antennæ to the utmost, and moving them alternately to the right and to the left. Woe to the unfortunate moth that comes within their reach. Aware of its danger, and of the defective sight of the bees, the moths adroitly avoid the slightest contact, and endeavour to insinuate themselves between the bees, so as to get unperceived into the hive, where they riot upon the honey which they find.

If bees require full day-light for the exercise of vision, it must at the same time be acknowledged, that, when they are so assisted, they appear to enjoy this sense in great perfection. A bee will recognise its habitation from great distances, and distinguish it at once from many others in a numerous apiary. It passes through the air in a straight line towards its object with extreme rapidity. On quitting the hive, it flies towards the field which is most in flower; and as soon as it has determined on its course, it takes as direct a line as a ball issuing from a musket. When it has collected sufficient provision, it rises in the air to discover its hive, and then darts forward with the velocity of an arrow, and with unerring precision in its aim.

Perceptions of temperature.

Their perceptions of heat and cold, which are generally referred to the sense of touch, appear to be extremely delicate. In several experiments of Huber's, the influence of the rays of the sun excited them to a vigorous action of the wings. It is well known that great cold reduces them to a state of torpor, and inferior degrees of cold are evidently unpleasant to them. They show by their conduct that they are sensible of alterations in the state of the weather for some time before we can perceive them. Sometimes, when working with great assiduity, they will suddenly desist from their labours; none will stir out of the hive, while all the working-bees that are abroad hurry home in crowds, and press forward so as to obstruct the entrance of the hive. Often when they are thus warned of the approach of bad weather, we can distinguish no alteration in the state of the atmosphere. Gathering clouds sometimes produce this effect on them; but perhaps they possess some species of hygrometrical sense, unconnected with any impression of vision. It is alleged that no bee is ever caught in a sudden shower, unless from some cause it has wandered very far from the hive, or been disabled by some accident from returning to it. There is reason for thinking, however, that much exaggeration has prevailed in the statements of authors as to the extent of this kind of foresight. Huber supposes that it is the rapid diminution of light that alarms them; for if the sky be uniformly overcast, they proceed on their excursions, and even the first drops of a soft shower do not make them return with any great precipitation. Bee.

Taste.

Their taste is perhaps the most imperfect of their senses. They exert hardly any discrimination in the collection of honey from different flowers. They are not repelled by the scent or flavour of such as are extremely offensive to our organs, and scruple not to derive supplies from such as are highly poisonous. In some districts in America, it is well known that the honey acquires in this way very deleterious properties. The qualities of honey are, indeed, observed to vary much, according to the particular situation from which it is obtained. The most stagnant and putrid waters, as we have already noticed, are resorted to by bees with the same avidity as the purest. In their selection of flowers they are guided by the quantity of honey they expect to meet with, and in no respect by its quality. When the scythe has cut down all the flowers which before yielded them a plentiful supply, they discontinue their excursions, although the weather be in all respects propitious. Their smell must, therefore, be sufficiently acute to enable them to discover the presence of honey at great distances. Direct experiment has, indeed, proved this to be the case. Mr Huber found that they proceeded immediately towards boxes which contained honey concealed from their view; and such in fact is the situation of the fluid of the nectarea in flowers. Some odours, especially the fumes of tobacco, and indeed all kinds of smoke, are highly obnoxious to them; this is the case, also, with the smell of oil of turpentine, alcohol, ammonia, the nitric and muriatic acids, and several other volatile chemical agents, upon receiving the impressions of which, they immediately set about ventilating themselves in the manner above described. But nothing excites their displeasure in a greater degree than the breath of the spectator; as soon as they feel which, they show signs of anger, and prepare to revenge it as an insult. The odour of the poison of their sting produces similar effects, exciting them to immediate rage and hostility.

Smell.

Although it is sufficiently clear that many insects possess the power of smell, yet the particular organ of this sense has never been accurately ascertained; and the opinions of naturalists have been much divided on the subject. These opinions have been supported more by arguments drawn from the analogy of what happens in other classes of animals, than by any direct experiments on insects themselves. We know that, in all animals respiring by means of lungs, the organs of smell are placed at the entrance of the passages of the air; and it has often been concluded, that in like manner the stigmata, or the orifices of the air-tubes, were the seat of this sense in insects. By others the antennæ have been assigned as the organs through which these impressions were conveyed to the sensorium. The experiments of Huber have proved that neither of these opinions is correct; and have satisfactorily shown that in the bee this sense resides in the mouth itself, or in its immediate vicinity. Here, indeed, would be its proper station, if this faculty be intended, as we may reasonably suppose it to be, to apprize the individual of the qualities of the food prior to its being eaten. When the mouth of the bee was plugged up with paste, which was allowed to dry before the insect was set at liberty, it remained quite insensible to the same odours to which it had before manifested the strongest repugnance.

Hearing.

It is generally supposed that bees possess the sense of hearing. The common practice of making a loud noise by drums and kettles in order to attract a swarm is founded on this supposition. But the evidence is by no means conclusive; for we find that they are nowise disturbed by a loud clap of thunder, or by the report of a gun, or any

Bee.

other noises that may happen to arise around them. It is, however, certain that they are capable of emitting a variety of sounds, which appear expressive of anger, fear, satisfaction, and other passions; and it would seem that they were even capable of communicating certain emotions to one another in this manner. Huber observed that the queens, during their captivity, sent forth a peculiar sound, which he supposes to be a note of lamentation. A certain cry or humming noise from the queen will strike with sudden consternation all the bees in the hive; and they remain for a considerable time motionless and stupified. Hunter has noticed a number of modulations of sound emitted by bees under different circumstances, and has instituted an inquiry concerning the means employed by them in producing these sounds; for an account of which we shall refer the reader to his paper in the *Philosophical Transactions*.

Instincts of bees.

If the function of sensation in insects be involved in doubt and obscurity, the knowledge of those more interior faculties which are the springs of voluntary action is hid in still deeper mystery. Buffon refuses to allow bees any portion of intelligence, and contends that the actions we behold, however admirably they are directed to certain ends, are in fact merely the results of their peculiar mechanism. Other philosophers, such as Reaumur, have gone into the opposite extreme, and have considered them as endued with extraordinary wisdom and foresight, as animated by a disinterested patriotism, and as uniting a variety of moral and intellectual qualities of a higher order. The truth, no doubt, lies between these overstrained opinions; but it is nevertheless extremely difficult to decide in what degree these respective principles operate in the production of the effects we witness. We have been too long in the habit of sheltering our ignorance of the causes of this class of phenomena, by referring them indiscriminately to what is called *instinct*, to submit to a cautious and patient investigation of the hidden springs of action. The term *instinct* should properly be regarded, not as denoting a particular and definite principle of action, whose operation we can anticipate in any new or untried combination of circumstances, but as expressive of our inability to refer the phenomena we contemplate to any previously known principle. Thus the actions which an animal performs in obedience to the calls of appetite are not properly said to be instinctive; nor can the term be applied to actions which are the consequence of acquired knowledge, and of which the object is with certainty foreseen by the agent. But when an animal acts apparently under a blind impulse, and produces effects useful to itself or to the species, which effects it could not have previously contemplated as resulting from those actions, it is then customary to say that it is under the guidance of instinct, that is, of some unknown principle of action. It will be proper, therefore, to keep this distinction in view in judging of the voluntary actions of the lower animals.

In no department of natural history is it more necessary to be aware of the proper import of the term instinct, than in studying the phenomena presented by the bee; for nowhere is it more difficult to discriminate between the regular operation of implanted motives, and the result of acquired knowledge and habits. The most striking feature of their history, and the one which apparently lays the foundation for those extraordinary qualities which raise them above the level of other insects, is the disposition to social union. It may in general, indeed, be remarked, that animals which associate together so as to form large communities, display a higher degree of sagacity than those which lead a solitary life. This is especially observable among insects. The spider and *Formica leonis* may exhibit particular talents, or practise particular stratagems in the pursuit and capture of their prey; but their history is limited to a single generation, and embraces none of those interesting relations which obtain between individuals composing the gregarious tribes, such as the ant, the wasp, and the bee. Among these we trace a community of wants and desires, and a mutual intelligence and sympathy, which lead to the constant interchange of good offices, and which, by introducing a systematic division of labour, amidst a unity of design, leads to the execution of public works on a scale of astonishing magnitude. The attachment of bees to their hive, which they defend with a courage and self-devotion truly admirable; their jealousy of intruders; their ready co-operation in all the labours required for the welfare of the community; their tender care of their young; the affection and homage which they bestow on their queen, and which they manifest on all occasions in the most unequivocal manner; imply qualities such as we could hardly persuade ourselves could animate a mere insect, on which we are in the habit of proudly looking down as placed in one of the lowest orders of created beings.

Bee.

We shall content ourselves at present with these general observations, as the instances which serve to illustrate their moral and intellectual character belong properly to the history of the different processes they follow in the construction of their combs, the hatching and rearing of their progeny, and the mode of conducting their migrations. To these subjects, therefore, we shall now proceed: and in order to present the most connected and complete account of their economy, we shall begin the history from the period when a new swarm has just occupied a hive, and when all the arrangements for their habitation, and the construction of the cells in which their eggs and provisions are to be deposited, are yet to be effected.

Preparation of the hive.

The first care of the labouring bees, on their settlement in their new abode, is to clean it out thoroughly. While one set of bees is thus employed, another is distributed about the country in order to procure the proper materials for blocking up the small holes and chinks of the hive, and for laying a firm foundation for the edifice which is to be constructed within it. The substance which is principally employed in this preliminary stage is *propolis*, a species of glutinous resin, of an agreeable aromatic odour, and reddish-brown colour, in process of time becoming darker, and acquiring a firmer consistence. According to the analysis of Vauquelin (*Mém. Soc. Agricult. Departem. Seine*), it is composed chiefly of resin, with a small proportion of wax, and of acid and aromatic principles. It is soluble in alcohol, ether, and oils, both fixed and volatile; and tinges the solvent of a beautiful red colour. Cadet has since ascertained in it the presence of benzoic and gallic acids. Reaumur had not been able to discover from what plants the bees collect this substance. Riem asserts that it is chiefly from pines and other trees of the fir kind. The recent observations of Huber have assisted in the solution of this question. On placing branches of the wild poplar tree before the hive, he found that the bees eagerly seized upon the varnish which exudes from the buds; and examining the chemical properties of this varnish, he identified it with the propolis with which the inside of the hive is lined.

Nature and origin of propolis.

Mode of its application.

The propolis adheres so strongly to the legs and feet of the bee which has collected it, that it cannot be detached without the assistance of its fellow-labourers. For this purpose the bee that is loaded presents its legs to the workers in the hive, which carry off with their jaws this adhesive substance, and immediately apply it, while yet ductile, all round the interior of the hive, and particularly over all the projecting parts; hence its name, of Greek

Bee.

derivation, signifying *before the city*. In like manner all the foreign bodies that are introduced into the common habitation, and are too heavy to be removed, are covered over with this resinous substance. If a snail, for instance, should happen to introduce itself into the hive, after dispatching it with their stings, they encrust it over with propolis. Mr Knight has observed that, besides propolis, bees will occasionally carry home, and employ as cement, other substances, having the same glutinous properties. He frequently covered the decorticated parts of trees, on which he was making experiments, with a cement composed of bees' wax and turpentine; and in the autumn has observed a great number of bees occupied in carrying off this substance. They detached it from the tree with their forceps, and the little portion thus obtained was then transferred by the first to the second leg, by which it was deposited on the thigh of the third, precisely in the same manner as the pollen of flowers is collected and transferred. Whilst the bees were employed in the collection of this substance, Mr Knight had many opportunities of observing their peaceful and patient disposition as individuals, which Mr Hunter had also in some measure noticed. When one bee had collected its load, and was just prepared to take flight, another often came behind it and despoiled it of all it had collected. A second, and even a third load was collected, and lost in the same manner; and still the patient insect pursued its labour, without betraying any symptoms of impatience or resentment. When, however, the hive is approached, the bee appears to be the most irritable of all animals, and is animated with the most vindictive spirit against a public enemy, without displaying any peculiar hostility in the revenge of a private injury.

Construction of the combs.

The next object of their labours is to prepare the combs, which are to be the receptacles for the eggs with which the queen is pregnant, and which are now about to be laid. The material employed for this purpose is not propolis, but wax, the production of which, by secretion from a particular set of bees who feed largely upon honey, was formerly explained. The bees are for this purpose actively employed in collecting honey, and in imparting it to their companions in the hive, who, when they have filled their crops with it, hang together in a thick cluster from the top of the hive, and thus remain in a state of inactivity for a considerable period. During this time the secretion of wax is proceeding, and may be seen collected in laminæ under the abdominal scales, whence it is removed by the hind-legs of the bee, and transferred to the fore-legs, and from thence taken up by the jaws. In this operation they are often assisted by their companions, who even directly seize upon the wax from under the abdomen of those who are before them. When a sufficient quantity of materials has thus been collected together, the process of building is commenced. But, in order to understand the subsequent operations, it is necessary to have a correct idea of the form of the cells which compose the combs. We shall, therefore, proceed to give some account of the structure when they have attained their perfect state.

Form of the combs.

The combs of a bee-hive are formed into parallel and vertical strata, each of which is about an inch in thickness, the distances between the surfaces of each being about half an inch, an interval which serves for the passage of the bees over both surfaces. They generally extend the whole breadth of the hive, and often descend the whole length, from the top to the bottom. They consist altogether of thin partitions, which inclose hexagonal cells about half an inch in depth and a quarter of an inch in diameter, opening on both surfaces of the comb, and closed by a partition common to those on both sides, and which occupies the middle distance between the two surfaces. This partition is not, however, a plane, but is composed of a collection of rhombs. Three, and sometimes four of these rhombs, inclined to one another at a certain angle, form the bottoms of each cell, which thus has the shape of a flattened pyramid, of which the basis is towards the mouth of the cell. The geometric form of each individual cell is, therefore, an hexagonal prism, terminated by a trihedral pyramid, the three sides of which pyramid are rhombs, which meet at the apex by their obtuse angles, and, forming oblique angles with the sides of the prism, truncate a portion of these, and convert them from rectangles, which they would be in a regular prism, into trapeziums. Of the two angles of these trapeziums adjoining to the base of the pyramid, one must be acute and the other obtuse, the acute angle of one trapezium being next to the acute angle of the adjoining trapezium, and the obtuse angle being in like manner next to another obtuse angle of the preceding trapezium, so that, in going round the base, we meet with pairs of acute and of obtuse angles alternately succeeding each other. The two adjoining acute angles of the trapezia are adjoining to two of the terminal rhombs, which here present their acute angles; so that at these points a solid angle of four planes is formed, all the angles being acute. Each pair of obtuse angles of the trapezia, on the other hand, are adjacent to the obtuse angle of one of the rhombs only, thus composing a solid angle of three planes, of which the angles are all obtuse; and these two kinds of solid angles succeed one another alternately all round the base of the pyramid, there being three of each kind, and six in all. The axis of each cell coincides, not with the axis of the cell on the opposite surface, but with one of its angles, so that each of the three obtuse angles at the base of the terminal pyramid corresponds to the central parts of three of the cells on the opposite side; and each of the sides of the pyramid, which closes a cell on one side, contributes in part to the closing of three of the cells on the opposite side. We may easily satisfy ourselves that this is the case, by piercing the centres of each of the three planes which close the bottom of a cell, with a pin, when, on turning the comb, the three pins will be found to have passed into three different cells on the opposite side.

Bee.

Geometric properties of the cells.

A structure of this kind is obviously the one of all others calculated to afford the greatest space for each cell, with the same expense of materials. It is easy to perceive, in the first place, that, in a plane surface, when a number of small spaces are to be divided by partitions, the hexagonal form is the one which comprehends the largest space compatible with the extent of the lines which inclose them. For the equilateral triangle, the square, and the regular hexagon, are the only regular forms that admit of being joined together in the same plane, without leaving interstices; and the proportion of the area to the periphery in every polygon increases as the figure consists of a greater number of sides, and is therefore greater in the hexagon than in any of the other two. The truth of this proposition was perceived by Pappus, and even its application to the subject of the honeycomb was made by that ancient geometrician. But the determination of the form and inclination that should be given to the partitions which close the bottoms of the cells, and which may of course belong equally to those on both sides of the comb, is a problem much more complicated and difficult of solution. It has exercised the skill of several modern mathematicians of great eminence, and has generally been resolved by the assistance of the infinitesimal calculus, or the methods of maxima and minima. A mistake has sometimes been committed in supposing that the capacity of the cells would be affected by varying

Bee. the inclination of the partitions, whereas, if abstraction be made of the thickness of these partitions, all the space which is gained on the one side must be obtained at the expense of the space on the other, and the sum total will therefore remain the same. This error has been pointed out by Le Sage of Geneva, and also by others. The whole question, therefore, resolves itself into that of the form producing the greatest saving of materials. Kœnig, the pupil of the celebrated Bernoulli, calculated that the angles of the rhombs, which should answer this condition, must be 109° 26′ and 70° 34′. Cramer, professor of mathematics in the university of Geneva, has given a very elegant demonstration of this problem, from which it results that the obtuse angle of the rhomb must be such, that its half has for its tangent the square root of 2. This is the case with the angle 54° 44′ 8″; the two angles of the rhomb are therefore 109° 28′ 16″ and 70° 31′ 44″. It follows also that the two diagonals of this rhomb are to one another in the same proportion as the side and diagonal of a square, that is, as 1 to 1·41421356237, &c. It is also another consequence from the same data, that the angles of the trapezia forming the sides of the hexagonal prism adjacent to the rhombs are precisely equal to those of the rhombs themselves, and that the solid angle formed at the apex of the pyramid, and which is composed of those equal obtuse angles, is precisely equal to each of the three angles at the base, which are also formed of three obtuse angles. It is also true that these are the only angles which will give this perfect equality. Maraldi had already made the same remark; and, assuming the principle of the equality of the angles as the basis of his reasoning, had calculated them on this hypothesis, making them 109° 28′ and 70° 32′, which is nearly accurate. To the same author we are indebted for the comparison of the results of theory with fact, by the admeasurement of the actual angles of the honeycomb; these he states to be about 110° and 70°, which is as near an agreement with theory as could well be expected.

Boscovich, who has also given a solution of the same problem, conceives that the equality of inclination of the planes gives greater facility to the construction of the comb, and might, therefore, be a motive of preference, independently of the greater economy of wax. Maclaurin has exercised his abilities in resolving this problem, and has demonstrated by simple geometry, that the most advantageous form is that which results from the supposed equality of the three plane angles forming the solid angles at the base. He estimates the saving of wax by partitions so constructed, above what would be required for a flat partition, at one fourth of the wax which would be wanted to complete the truncated sides of the cells, so as to form them into rectangles. L'Huillier, in the *Memoirs of the Berlin Academy*, has given a demonstration which is remarkable for its simplicity, and for its involving none but elementary propositions; he values the economy of wax at $\frac{1}{51}$ of the whole wax employed. Le Sage, as appears from the life of that philosopher by Professor Prevost, has shown that this celebrated problem reduces itself to the finding of the angle at which two planes with a given inclination (such as 120°) can be cut by a third plane, so as to make all the angles resulting from the section equal to one another.

But a more essential advantage than even the economy of wax results from this structure, namely, that the whole fabric has much greater strength than if it were composed of planes at right angles to one another; and when we consider the weight they have to support when stored with honey, pollen, and the young brood, besides that of the bees themselves, it is evident that strength is a material requisite in the work.

Bee.

It has often been a subject of wonder how such diminutive insects could have adopted and adhered to so regular a plan of architecture, and what principles can actuate so great a multitude to co-operate by the most effectual and systematic mode in its completion. Buffon has endeavoured to explain the hexagonal form by the uniform pressure of a great number of bees all working at the same time, exerted equally in all directions in a limited space; and illustrates his theory by supposing a number of similar cylinders compressed together, and taking the form of hexagonal prisms by the uniform expansion of each. The analogy of the forms produced by the law of crystallization,—of the figures assumed by various parts in the animal and vegetable world, such as the skin of the bat, and the inner coat of the second stomach of ruminant quadrupeds,—is also adduced by this captivating but superficial writer in support of his argument. But however plausible this theory may at first sight appear, it will not stand the test of a more serious examination. The explanation he has attempted applies no further than to the inclination of the sides of the cells; but he did not take into account, perhaps from not having studied the subject mathematically, the inclinations and forms of the planes which close each cell, and so curiously conspire on both sides to serve a similar office, while they at the same time accurately fulfil a refined geometrical condition. But it is sufficient confutation of the whole theory to show, that it is directly at variance with the actual process employed by the insects in the construction of their combs. Buffon's theory of the formation of the combs.

It might be supposed that bees had been provided by nature with instruments for building of a form somewhat analogous to the angles of the cells; but in no part, either of the teeth, antennæ, or feet, can any such correspondence be traced. Their shape in no respect answers to that of the rhombs, which are constructed by their means, any more than the chisel of the sculptor resembles the statue which it has carved. The shape of the head is indeed triangular, but its three angles are acute, and different from that of the planes of the cells. The form of the plates of wax, as they are moulded in the pouches into which this substance is secreted, is an irregular pentagon, in no respect affording a model for any of the parts which compose the honeycomb. Hunter, observing that the thickness of the partition was nearly equal to that of the scale of wax, thought that the bees apply these scales immediately to the formation of the partition, by merely cementing them together. Reaumur, notwithstanding the use of glass hives, had not been able to discover the mystery of their process of architecture; but inferred, from what he saw, that the wax was rejected from the stomach in the form of a white frothy liquor. No naturalist, indeed, prior to Huber, had been able to follow these insects in their labours, on account of their crowding together in a thick mass while they are building; but the expedients resorted to by that ingenious philosopher have unfolded the whole process, which he has given with great detail in the second volume of his *Observations sur les Abeilles*. Huber witnessed the whole of their actions, and saw that each bee drew out, with its hind feet, one of the plates of wax from under the scales where it was lodged, and, carrying it to the mouth in a vertical position, turned it round, so that every part of its edge was made to pass in succession under the cutting edge of the jaws; it was thus soon divided into very small fragments, while at the same time a frothy liquor was poured upon it from the tongue, so as to form it into a perfectly plastic mass. This liquor gave the wax a whiteness and opacity which it did not possess originally, and rendered it at the same time tenacious and ductile. A quantity of wax thus prepared for use is accumulated, Mode of their construction.

Bee. and applied to further the work in the manner we are presently to describe.

But, in considering the process by which the comb is formed, a circumstance should be pointed out, which seems not to have been particularly noticed by any author except Huber; and yet it is one of essential importance in studying their process of architecture;—namely, that the first row of cells on either side are of a form very different from that of the subsequent rows. As they take their origin from a plane surface, two of the sides necessary to complete the hexagon are cut off by this plane, so that the general form of the orifice is pentagonal; and the bottom of the cells on one side is composed of two equal rhombs only, and on the other side of two trapezoidal planes, with one rhomb. Such a modification of shape was necessary, in order to prepare the way for the regularly-formed cells which were to follow.

The foundations of the combs are laid by the bees raising a solid block or plate of wax of a semicircular form. In this they scoop out a small vertical channel, of the size of an ordinary cell. The sides of this channel are then strengthened by additions of wax. On the opposite side two other channels are formed, one on each side of the plane opposite to the former channel. The extremities of these channels, which at first present a curved outline, are then fashioned into straight walls, forming an angle at each vertex. The bottom of each cell being thus sketched out, the design is completed by raising walls round the sides. Different bees generally work on the opposite sides at the same time, and appear to have some perception of the thickness of the partitions, and of the situation of the opposite walls, in which they are perhaps guided by slight prominences, occasioned by the depressions which correspond to them on the other side; and they scrape off the wax in those places where its thickness is greatest; that is, where the bees on the other side had accumulated materials. In this way, then, in constructing the successive rows, the axis of each cell will be found to occupy the most retiring parts of the partition, and will be opposite to the junction of three of the opposite cells.

Soon after the bees have completed the foundations, and constructed a few of the cells of the central comb, they begin two others, one on each side, at the proper distance, and in this manner continue to form others in succession, in proportion as the former are advanced. Their object at first seems to be to extend the surface of the work, so as to admit of the greatest possible number of workers being employed at one and the same time. In this way, then, the work proceeds from all points at once, new cells being begun before the former are completed, so that the whole comb, while it is in progress of construction, has a semi-lenticular shape, broader at the top, and tapering below and towards the sides. It extends downwards, however, more rapidly than in any other direction, and its surfaces do not become parallel to each other till the last stage of the building process. When this is completed, the whole is further strengthened by an additional coating of propolis round the margin of all the cells; and the junctions of every plane, both of the sides and bottoms of the cells, are also soldered together by a lining of the same substance. The edges of the combs are also secured in their situations by being glued to the side of the hive, and supported by fresh abutments of propolis. Sometimes a mixture of wax and propolis, manufactured by the bees themselves, is employed as the cementing material. The first coating of this compound substance is denominated *Commosis* by Pliny, and described as having a bitter taste; the second, or the *Pissoceros* of the same author, is stated to be of a thinner consistence, and more adhesive than the former; while the third substance or propolis is completely solid. Bee.

The cells recently constructed are perfectly white, but in a short time they are found of a yellow tint, which becomes gradually deeper, and, when very ancient, gives them a dark brown cast. It is therefore easy to distinguish in a hive the successive periods of formation of different portions of the combs. From the researches of Huber, it appears that these variations of colour are not owing to any changes in the wax itself, but to additional coatings of a peculiar varnish, consisting of propolis and a colouring matter. The latter differs materially from propolis, being wholly insoluble in alcohol. It loses its colour by the action of nitric acid or the light of the sun. Its origin has not yet been discovered; nor has the mode in which it is applied been clearly made out; although Huber presumes, from his observations, that they spread it by means of their mandibles, which he has seen them rub against the sides of the cells, while they acquired a yellow colour from the operation.

Such is the general outline of the architectural labours of the bee. A number of modifications are however met with, adapting them to various purposes and to new circumstances. The cells are required to be of different sizes for the reception of different sorts of eggs and larvæ The smallest, which are also the most numerous, are appropriated to the eggs of the working bees; a larger sort receive those of the males; and a small number of very large cells are destined for the education of the young queens, and are therefore called royal cells. The first set are generally five and one third lines in depth, and two and a half in diameter; the second are from seven to seven and a half lines in depth, and three and three fourths in diameter; while the royal cells are above one inch deep, one third of an inch wide, and their walls are about one eighth of an inch in thickness. Other cells, again, are set apart as magazines of honey or of pollen; they are made twice as deep as the common cells, and their axes are inclined to the horizon, so that their mouths are in the highest part, and their liquid contents may be more easily retained. When these are filled, they are closed up by the bees with a wall of wax, and opened only when necessity requires. Different kinds of cells

The regularity of the cells is often disturbed in consequence of the admixture of rows of larger cells with those of smaller dimensions; but the pyramidal partitions are adapted by successive gradations to these changes; so that in many rows of what may be called cells of transition, the bottom presents four planes instead of three, two being trapeziums, and the other two irregular hexagons. These irregularities are met with chiefly in the combs most distant from the central one. When an abundant supply of honey induces them to lay up a large quantity in store, they build up for this purpose the walls of common cells, so as to give them a greater depth. The royal cells are often raised from the ruins of a number of other cells, which are destroyed to make room for them; they are usually built on the edge of some of the shorter combs, and often in the very centre of the hive. Sometimes there are but three or four of them; at other times eleven, or even fourteen, have been counted in the same hive. They are formed of a mixture of propolis and wax; their form is oblong, resembling that of a pear; their position is always vertical, so that when they arise from amidst other cells, they are placed against the mouths of those cells, and project beyond the common surface of the comb. They are perfectly smooth on the inner surface; while their outer side is covered with a kind of hexagonal fret-work, as if they were intended for the foundation of regular cells. Cells of transition.

As soon as a sufficient number of cells have been con-

structed, the queen begins to deposit her eggs. In those that have been impregnated the preceding year, the oviducts begin to swell early in the spring, so that by the month of March they are ready to come forth. The queen-bee is, therefore, the earliest breeder of any insect we are acquainted with. But the young queens are capable of laying eggs thirty-six hours after impregnation. It appears to be now well ascertained by the experiments of Huber, that she is aware of the nature of the eggs she is laying, and deposits each in the kind of cell adapted to receive it. She may be seen examining attentively the capacity of the cell before laying her egg. She passes thus from one cell to another, allowing herself hardly any interval of repose. She commonly lays two hundred eggs in a day; but if the weather be warm, and vegetation luxuriant, she will lay a much greater number. The cold of autumn suspends this process. The eggs first produced are those of labourers, and their deposition continues for ten or twelve days, during which interval the working bees are busily employed in constructing the larger cells. The queen next acquires a considerable increase of size, so as to walk with difficulty. She then lays male eggs in the large cells, during a period of from sixteen to twenty-four days. They are less numerous than the former eggs, in the proportion of one to thirty.

Deposition of the eggs.

These industrious insects now set about constructing royal cells; and the queen-bee, having finished her deposition of male eggs, begins again to lay those of the common bees; and finding royal cells open for their reception, deposits a single egg in each, but only at intervals of one or two days; the common cells receiving those laid in the mean time. When the hive is not sufficiently numerous, or the season has been unproductive, no royal cells are formed; and the education of a queen is not attempted.

As soon as the eggs are deposited, the bees eagerly seek for that species of nourishment on which the larva is to be fed. This consists of pollen, with a proportion of honey and of water, which is partly digested in the stomachs of the nursing bees, and which is made to vary in its qualities according to the age of the young. Pollen is afforded by flowers in the spring in such abundance that the bees of a single hive will often carry home above a pound of this substance in one day. The eggs of bees are of a lengthened oval shape, with a slight curvature, and of a bluish white colour. They are hatched without requiring any particular attention on the part of the bees, except that of keeping up a proper temperature; in which case three days are sufficient for the exclusion of the larva. The larva has the appearance of a small white worm without feet, which remains generally coiled up at the bottom of the cell. The nursing bees feed it with great assiduity, with the kind of jelly above described, and in every respect exhibit the greatest attachment for them. Mr Hunter says that a young bee-maggot might easily be brought up by any person who would be attentive to feed it. It may be seen opening its two lateral pincers to receive the food, and then swallowing it. As it grows up it casts its cuticle, like the larvæ of other insects. In the course of five or six days it has attained its full size, and nearly fills the cell in which it is lodged: it now ceases to eat, and the bees close up its cell with a covering of wax, or rather a mixture of wax and propolis, which they possess the art of amalgamating together. During the next thirty-six hours the larva is engaged in spinning its cocoon, and in three days more it is converted into the state of pupa or chrysalis. In this state it is perfectly white, and every part of the future bee may be distinguished through its transparent covering. In the course of a week it tears asunder its investing membrane, makes its way through the outer wall of its prison, and emerges in its perfect form. Reckoning from the time that the egg is laid, it is only on the twentieth day of its existence that this last metamorphosis is completed. No sooner has it thus emancipated itself, than its guardians assemble round it, caress it with their tongues, and supply it plentifully with food. They clean out the cell which it had been occupying, leaving untouched, however, the greater part of the web, which thus serves to bind together still more firmly the sides of the comb. The colour of the bee when it quits the cell is a light gray; it requires two days before it can attain sufficient strength for flying. The metamorphoses of the male bee follow the same progress, but require a few days longer for their completion, occupying about twenty-four days from the time of the egg being laid to the attainment of the perfect state.

Nourishment of the larvæ.

The eggs deposited in the royal cells are precisely similar to those of the working bees, and might be substituted the one for the other. The larva arises from it precisely in the same manner, and does not differ from the larva of the workers. But the attention of the nursing bees is more incessantly bestowed on them; they are supplied with a peculiar kind of food, which appears to be more stimulating than that of ordinary bees. It has not the same mawkish taste, and is evidently acescent. It is furnished to the royal larva in greater quantities than it can consume, so that a portion always remains behind in the cell after its transformation. The growth of the larva, and the development of all its organs, are very much accelerated by this treatment; so that in five days it is prepared to spin its web; and the bees inclose it by building up a wall at the mouth of its cell. The web is completed in twenty-four hours; two days and a half are consumed in a state of inaction, and then the larva transforms itself into a pupa. It remains between four and five days in this state; and thus, on the sixteenth day after the egg has been laid, it has produced the perfect insect. When this change is about to take place, the bees gnaw away part of the wax covering of the cell, till at last it becomes pellucid from its extreme thinness. This must not only facilitate the exit of the fly, but may possibly be useful in permitting the evaporation of the superabundant fluids.

Process of rearing the queen-bee.

But the queen-bee, although perfectly formed, is not always at liberty to come out of her prison; for if the queen-mother be still in the hive, waiting a favourable state of the weather to conduct another swarm, the bees do not suffer the young queens to stir out; they even strengthen the covering of the cell by an additional coating of wax, perforating it with a small hole, through which the prisoner can thrust out its trunk in order to be fed by those who guard it. The royal prisoners continually utter a kind of plaintive song, the modulations of which are said to vary. One consequence of their detention is, that they are capable of flying as soon as they are set at liberty. But the motive of this proceeding on the part of the bees who guard them, is to be found in the implacable hatred which the old queen bears against all those of her own sex, and which impels her to destroy without mercy all the young queens that come within her reach. The working bees are, on this account, very solicitous to prevent her even approaching the royal cells while there is any prospect of a swarm being about to take place. They establish themselves as a guard around these cells, and, forgetting their allegiance on this occasion, actually beat her off as often as she endeavours to come near them. If, on the other hand, the swarming season is over, or circumstances prevent any further swarms from being sent off, the bees do not interpose any obstacle to the fury of the old queen, who immediately begins the work of destruction, transfixing with her sting, one after the other, the whole of the royal brood while they are yet confined

Rivalship of the queens.

Bee.

in their cells. It is observed by Huber, that the royal larvæ construct only imperfect cocoons, open behind, and enveloping only the head, thorax, and first ring of the abdomen; and he conceives that the intention of nature in this apparent imperfection is, that they may be exposed to the mortal sting of the queen, to whom they may be given up as a sacrifice.

When the old queen has taken her departure along with the first swarm, the young queens are liberated in succession, at intervals of a few days, in order to prevent their attacking and destroying one another, which would be the infallible consequence of their meeting. This exterminating warfare is prevented by the vigilance of the bees who guard them, so long as new swarms are expected to take place. When a young queen is liberated, she is, like others of her sex, anxious to get rid of her rivals, and even at that early age seeks to destroy her sisters, who are still confined in the other royal cells; but as often as she approaches them she is bit, pulled, and chased without ceremony by the sentinels. But when the season is too far advanced for swarming, or when the hive is too much exhausted in its population by the swarms that have already been sent off, they no longer interfere in preserving peace, and the first that acquires her liberty proceeds to massacre all her rivals. If two or more queens should happen to issue out at the same moment, they mutually seek each other, and fight till one is killed, and the survivor is immediately received as the sovereign of the hive. The bees, far from seeking to prevent these battles, appear to excite the combatants against each other, surrounding and bringing them back to the charge when they are disposed to recede from each other; but when either of the queens shows a disposition to approach her antagonist, all the bees forming the clusters instantly give way to allow her full liberty for the attack. The first use which the conquering queen makes of her victory is to secure herself against fresh dangers by destroying all her future rivals in the royal cells; while the other bees, who are spectators of the carnage, share in the spoil, greedily devouring any food which may be found at the bottom of the cells, and even sucking the fluid from the abdomen of the pupæ before they toss out the carcasses.

Impregnation.

The impregnation of the queen-bee was formerly involved in the deepest obscurity, and has given rise to a multitude of very fanciful opinions. Some have denied that any intercourse with the male was necessary for the fecundation of the eggs. Swammerdam supposed that the mere effluvia proceeding from the males, where they were collected in clusters, was sufficiently active to produce this effect, by penetrating the body of the female. Huber proved, by a decisive experiment, that no such consequence resulted from these effluvia. Maraldi imagined that the eggs were fecundated by the drones, after being deposited in the cells, in the same way that the spawn of fishes is rendered prolific by the milters. Mr Debraw of Cambridge, in a paper published in the *Philosophical Transactions*, fancied that he had seen the milt-like fluid in the cells. But this appearance has been shown by Huber to be a mere optical illusion, arising from the reflection of light at the bottom of the cell. When the males are excluded from the hive, the queen is as fertile, and the eggs as prolific, as when they are present. Hattorff supposed that the queen is capable of impregnating herself; an opinion which was supported by Schirach and Wilhelmi, and was even favourably received by Bonnet, as it in some measure accorded with his discoveries respecting the aphis, of which our readers will find an account in the article Aphis. (See Entomology, *Index*.) Linnæus was of opinion that an actual union between the sexes took place, and Reaumur fancied that he had seen this happen within the hive. There is, however, great reason to think that he was mistaken. Huber has clearly proved that the queen is never impregnated as long as she remains in the interior of the hive; and, if confined within it, continues barren, though surrounded by males. It is only during her flight, at a considerable height in the air, that the male has complete access to her so as to effect the impregnation. In half an hour the queen-bee returns to the hive with unequivocal proofs of the intercourse that has taken place, for she has in fact robbed the drone of the organs concerned in this operation; and the drone, thus mutilated, is left to perish on the ground. From its being necessary that the queen should fly to a distance in order to be impregnated, Huber infers the necessity of a great number of drones being attached to the hive, that there may be a sufficient chance of her meeting one of them during her aërial excursion.

Bee.

Preparation for swarming.

We are now to direct our attention to the migrations of bees, by which new colonies, similar to that which had originally peopled the parent hive, are founded. The final causes of this phenomenon are sufficiently obvious; but it does not so clearly appear to what circumstances it is immediately owing. The increasing population of a hive probably occasions inconvenience from the want of room, the increase of heat, and the greater vitiation of the air; inconveniences which become still more serious as the summer advances. The spring is accordingly the commencement of the swarming season; no swarm, indeed, will ever take place while the weather is cold, nor until the hive is well stocked with eggs of every kind. The queen-bee, in consequence of the great number of eggs she has been laying, is now reduced to a more slender shape, and is well fitted for flight. Her aversion for the royal brood, which she seems to foresee will in no long time become able to dispute the throne with her, and the vain attempts she makes to destroy them in the cradle, in which she is invariably repelled by the bees who guard them, produce in her a constant restlessness and agitation, which, as Huber represents it, rises to a degree of delirium. This frenzy, from whatever cause it may originate, is communicated to the workers; they may be seen hurrying to and fro in the combs, with evident marks of impatience; the heat of the hive is increased by their tumultuous movements; it sometimes rises suddenly, on these occasions, from 92° to above 104°. A general buzz is heard throughout the hive. This state recurs from time to time, for some days before the swarm is actually on the wing; and the interval is occupied in making preparations for the approaching expedition. Provisions are collected in greater quantity by the working bees. Mr Hunter killed several of those that came away, and found their crops full, while those that remained in the hive had their crops not near so full. Scouts are sent out to look for a proper habitation. Mr Knight, in the *Philosophical Transactions*, gives us a curious account of his observations on their manœuvres in this respect. In the cavity of a hollow tree, which, by the application of a board, had been fitted up for the reception of the swarms, he constantly observed, "that, about fourteen days previous to their arrival, a small number of bees, varying from twenty to fifty, were every day employed in examining, and apparently in keeping possession of, the cavity; for if molested, they showed evident signs of displeasure, though they never employed their stings in defending their proposed habitation. Their examination was not confined to the cavity, but extended to the external parts of the tree above; every dead knot particularly arrested their attention, as if they had been apprehensive of being injured by moisture, which this might admit into the cavity below; and they apparently did not leave any part of the bark near the ca-

Bee.

vity unexamined. A part of the colony which purposed to emigrate appeared in this case to have been delegated to search for a proper habitation; and the individual who succeeded must have apparently had some means of conveying information of his success to others; for it cannot be supposed that fifty bees should each accidentally meet at and fix upon the same cavity, at a mile distant from their hive, which Mr Knight has frequently observed them to do, in a wood where several trees were adapted for their reception; and indeed he observed that they almost uniformly selected that cavity which he himself thought was the best adapted to their use. It not unfrequently happened that swarms of his own bees took possession of these cavities, and such swarms were in several instances followed from his garden to the trees; and they were observed to deviate very little from the direct line between the one point and the other, which seems to indicate that those bees who had formerly acted as purveyors now became guides."

Departure of the swarm.

On the day on which the swarm quits the hive, few of the workers roam to any distance, but several are seen performing circles in the air round the hive. The noise is on a sudden hushed, and all the bees enter the hive; this silence announces their immediate departure. A few workers appear at the door, turn towards the hive, and striking with their wings, give, as it were, the signal for flight. All those who are to accompany the expedition rush towards the door, and issue forth with wonderful rapidity, rising in the air and hovering for some time, as if in order to wait for the assemblage of the whole troop; then, following the motions of the queen, they settle wherever she alights, forming a dense cluster around her. Sometimes, from weakness, or some other cause, she returns back to the hive, and is immediately attended thither by the rest. But if the weather be fine, the expedition is only deferred for one or two days, and they again take their departure. If their return be owing to the loss of their queen, they remain a fortnight or longer before the attempt to migrate is renewed, and then the swarm is much larger than before, which renders it probable that they have waited for the queen that was to go off with the next swarm. Sometimes, when every thing indicates an approaching emigration, the passage of a cloud across the sun will suspend all their operations, and the previous bustle gives place to a state of perfect calm. But, if the day be not far advanced, the breaking out of sunshine will renew the commotion, and determine the moment of actual flight.

Succession of swarms.

The swarm having rested for some time on the first landing-place, and collected the whole of its numbers, soars again in the air, keeping in a close phalanx, and directing its course with great velocity to the spot which their guides had selected; giving out, at the same time, a loud and acute-toned hum by the action of their wings.

The parent hive, thus deserted by its queen and a large proportion of its inhabitants, is busily occupied in repairing its loss. The bees which remain quietly pursue their labours; the young brood, soon arriving at maturity, quickly fill up every deficiency; and young queens, being allowed their liberty, one after the other, conduct in their turns new swarms, in the same manner as the first. The second swarm is not sent off till after the space of from five to ten days after the first. The following swarms succeed quicker to each other, but consist of smaller numbers than the earlier ones. If it happen that two queens are found in a swarm, either the swarm divides itself into two, and have separate destinations, or a single combat between the queens decides on which of them the empire is to devolve. Sometimes, indeed, they appear not to perceive each other, and the parties belonging to each construct separate combs within the same hive; but no sooner do these combs come in contact, and thus give occasion to the queens meeting each other, than the contest begins, and it does not terminate but by the death of one of the rival queens. Successive swarms are sent off as long as the increase of population admits of it, and the number thus produced in a season depends on a variety of circumstances, such as the abundance of flowers, and the warmth of the climate, and the capacity of the hive. Bosc, while he was French consul in Carolina, found a hive in the woods which had been robbed of its wax and honey by the negroes: he contrived to convey the bees in his hat to a hive in his garden; he obtained from this hive eleven swarms before the end of autumn; and these again afforded him the same number of secondary swarms, so that, by the end of the year, he had twenty-two hives stocked from the one he had thus saved from destruction. In this country a hive commonly sends off only two, and sometimes three swarms in the course of the summer.

Bee.

Massacre of the drones.

Very few drones accompany the new colonies, so that almost all those produced in the spring remain in the hive. But when the queens are impregnated, and no new swarms are about to take place, the workers, who had till then suffered them to live unmolested in the hive, are on a sudden seized with a deadly fury towards them, and a scene of carnage ensues. This usually happens in July or August. They chase their unhappy victims in every quarter, till they seek a refuge at the bottom of the hive, where they collect in crowds, and are indiscriminately, and without a single exception, massacred by the working bees, who, with implacable fury, transfix them with their stings, and throw the dead bodies out of the hive. So great is their antipathy to all the race of drones, that they destroy, at the same time, the male eggs and larvæ, and tear open the cocoons of their pupæ, in order to devote them to one common destruction. This sacrifice of the males is not, however, the effect of a blind and indiscriminating instinct; for if a hive be deprived of its queen, the massacre does not take place, while the hottest persecution rages in all the surrounding hives. In this case the males are allowed to survive one winter.

Provision for the winter.

Having thus got rid of the useless mouths, which consumed, without any advantage to the public, a large portion of their provisions, the bees spend the remainder of the summer in collecting stores of honey and of pollen for the ensuing winter. Their gleanings are now less abundant than in the spring, and require more labour in the search and collection. But at this season the leaves of many kinds of trees, which are covered in the morning with a saccharine fluid that transudes through them, furnish them with a species of nourishment, which, though of very inferior quality to the fluid of the nectarea, still contributes to their support. Fruit is also attacked by bees, after the cuticular covering has been broken through by birds or snails. They also find nutriment in the *honey-dew*, which, as already stated, is an excrementitious fluid from the aphis. Often, however, these resources fail, and the hive is threatened with famine. On these occasions the distressed bees frequently betake themselves to plunder. Spies are sent out to examine the neighbouring hives; allured by the smell of honey, they examine the appearance and strength of its possessors; and, selecting the weakest hive as the object of attack, they begin a furious onset, which costs great numbers their lives. If the invaders should fail in their attempt to force the entrance, they retreat, and are not pursued by those whom they have assailed; but if they succeed in making good the assault, the war continues to rage in the interior of the hive, till one party is utterly exterminated; reinforcements are sent for by the invading army, and the bees

Mutual depredations.

from the neighbouring hives often join the assailants and share in the plunder. In a short time the whole of the enemy's magazines are completely emptied. If, on the other hand, the invaders should be defeated, the successful party is by no means safe from the attacks of the bees from other hives, if any of them should chance to have mingled in the fray, and especially if they have once penetrated as far as the magazines, for in that case they are sure to return, accompanied with a large reinforcement, and the unfortunate hive that has once been attacked ultimately falls a sacrifice to these repeated invasions.

The close of autumn puts a period to their labours abroad. They then live on the provisions they have amassed, till the cold of winter reduces them to a torpid state; from which they awake on the return of vernal warmth, and renew the same circle of labours. Sometimes the strong light reflected from the snow during a clear sunshine deceives them with the appearance of warmth, and some bees are tempted to issue forth in order to collect provisions. All who thus venture out perish by the cold in a few minutes.

Duration of life.

Bees seldom die a natural death. They are at all times exposed to a variety of accidents, which thin their numbers; so that the average duration of their lives does not exceed one year. We may conclude that the whole generation is renewed in that space of time, from the results of experiments which have been tried of marking all the individuals of a hive in the spring, when it was found that none were in existence the next season. They are the natural prey of a number of quadrupeds, birds, and insects; many are overtaken by stormy weather, or fly to too great a distance, and never find their way back again to the hive; others are benumbed by cold; and numbers perish in battle with others of their own species, or lose their lives by being unable to withdraw the stings which they have employed against their enemies. The fecundity of the queen-bee is, however, adequate not only to repair these losses, but to multiply the population in a very high progression. It is computed that in France a single queen will lay from 30,000 to 60,000 eggs. This however varies according to the climate; for in Carolina and the West Indies they are known to produce at least three times this number. A single intercourse with the male is sufficient for the fecundation of all the eggs which the queen lays for at least two years, as has been proved by Huber; but its influence probably extends to all the eggs which the queen may lay during the rest of her life. The same queen has been observed to conduct swarms for two successive years; but the natural period of their lives is not known with any certainty. The ancients supposed it to be seven years; but Féburier suspects that, like the males, they are destroyed by the labourers when they have fulfilled their destination; for he was witness to an attack made by six labourers on a queen, whom he rescued with difficulty. Mr Hunter observes, that, judging from analogy, a bee's natural life is limited to a certain number of seasons; for he conceives that no individual insect of any species lives one month longer than the others of the same species. In the bee, one might suppose the period of life to be equal to the time that a hive can last; but this is not a necessary consequence, since they keep up a succession of generations. The comb of the hive may be said to be the furniture and storehouse of the bees, which by use must wear out; but, independently of this, it will in time become unfit for use, by the accumulation of cocoons, together with the excrements of the maggots, which are never removed. The former, indeed, lines the whole cell, top, sides, and bottom; and may be distinguished from the cocoons of former maggots that have been hatched in the same cell, by a portion of dried excrement, which is interposed between them at the bottom of the cell. Mr Hunter counted above twenty different linings in one cell, and found the cell about one quarter or one third filled up. A piece of comb so circumstanced, when boiled for the wax, will keep its form, and the small quantity of wax is squeezed out at different parts, as if squeezed out of a sponge, and runs together in the crevices; while a piece of comb that never has been bred in, even of the same hive, melts almost wholly down. Hence the combs can only last a certain number of years. However, to make them last longer, the bees often add a little to the mouth of the cell, which is seldom done with wax alone, but with some sort of mixture; and they sometimes cover the silk lining of the last chrysalis; but all this, observes Mr Hunter, makes such cells clumsy, in comparison of the original ones.

Fecundity of the queen-bee.

Durability of the combs.

We have thus given an account of the principal facts in the history of bees, as far as they relate to the usual or natural condition of these insects. We shall conclude with the relation of several curious phenomena which they exhibit under particular and unusual circumstances, in which accident, or the designs of the experimenter, may have placed them.

What happens when they lose their queen.

The loss of the queen is an event which has the most marked influence on their conduct. Although the queen is constantly an object of attention and of strong affection to the whole community, they are not immediately sensible of her absence when she is removed from the hive. The ordinary labours are continued without interruption, and it is not till a whole hour has elapsed that symptoms of uneasiness are manifested, and it is even then only partially displayed. The inquietude begins in one part of the hive, the workers become restless, abandon the young which they were feeding, run to and fro, and, by striking each other with their antennæ, communicate the alarming intelligence very quickly to their companions. The ferment soon extends to the whole community; the bees rush precipitately out of the hive, and seek for their lost queen in every direction. This state of confusion continues for two or three, and sometimes for five hours, but never longer. Tranquillity is again re-established; they return to their labours; and selecting one of the larvæ that is not more than three days old, they break down two of the contiguous cells, sacrificing the larvæ contained in them, and proceed to build up one royal cell from their ruins. They then supply the worm with the food necessary to promote its quick growth, and, leaving untouched the rhomboidal bottom, they raise around it a cylindrical inclosure. In three days the larva has grown to such a size as to require an extension of its lodging, and must inhabit a cell nearly of a pyramidal figure, and hanging perpendicularly. A new pyramidal tube is therefore constructed with the wax of the surrounding cells, which is soldered at right angles to the first, and the bees, working downwards, gradually contract its diameter from the base, which is very wide, to the point. In proportion as the worm grows the bees labour in extending the cell, and bring food, which they place before its mouth and round its body, forming a kind of coiled zone around it. The worm, which can move only in a spiral direction, turns incessantly to take its food before its head; it insensibly descends, and at length arrives at the orifice of the cell. It then transforms itself into a pupa, is inclosed with a covering of wax, as before described, and, in the space of ten days, the original loss is thus repaired by the birth of a new queen. Schirach found, that if a number of bees be confined with even a single larva, which, in the natural course would have become a working bee, they immediately set about giving it the royal education above related, and thus raise it to the dignity of queen.

Bee. This discovery, which has since been amply confirmed by recent experiment and observation, was at first chiefly admired for its singularity in a physiological point of view. But it is evidently capable of being very advantageously applied towards the formation of artificial swarms, or new colonies of bees, by which the produce in honey and wax may be proportionally augmented. In the early months of spring, and even during the succeeding months, so late as November, M. Schirach cut off from an old hive a piece of that part of the comb which contained the eggs of the working bees, taking care, however, that it likewise included some worms hatched within the three preceding days. He fixed this in an empty hive, or box, together with a portion of honey-comb, &c.; or, in other words, with a sufficiency of food and building materials, or wax, for the use of the intended colony. He then put into, and confined within the box, a sufficient number of common working bees, taken from the same or any other hive. As soon as the members of this small community found themselves deprived of their liberty, and without a queen, a dreadful uproar ensued, which continued generally, with some short intervals of silence, for the space of about 24 hours; during which time it is to be supposed they were alternately meditating and holding counsel on the future support of the new republic. On the final cessation of this tumult, the general and almost constant result was, that they betook themselves to work, first proceeding to the construction of royal cells, and then taking the proper measures for hatching and feeding such of the brood as were placed within them. Sometimes even on the second day the foundations of one or more royal cells were perceptible. This operation has been hitherto conducted within doors. The new colony may now be safely trusted in the garden, if the weather be warm, and have the liberty allowed them of passing out of the box; of which they instantly avail themselves, and are seen in a short time almost totally to desert their new habitation. In about two hours, however, they begin to re-enter it. We should not neglect to observe, that if they should be placed near the old hive from which they were taken, they will very often attempt to enter it, but are as constantly repulsed by their former companions and brethren. It is prudent, therefore, to place them at a distance from the mother state, in order to avoid the inconveniences of a civil war. The final result of the experiment is, that the colony of working bees thus shut up, with a morsel of common brood, not only hatch it, but are found, at the end of eighteen or twenty days, to have produced from thence one or two queens, which have apparently proceeded from worms of the common sort, pitched upon by them for that purpose; and which, under other circumstances, that is, if they had remained in the old hive, would, in the course of their metamorphosis, have attained only to the condition of working bees. In the present instance, the common worm appears to be converted by them into a queen-bee merely because the hive was in want of one. Hence we may justly infer that the kingdom of the bees is not, if the expression may be used, a *jure divino*, or hereditary monarchy, but an elective kingdom; in which the choice of their future ruler is made by the body of the people.

While the hive remains without a queen, swarming can never take place, however crowded the hive may be. The young queens are suffered to come out of their cells without impediment, and, after a number of deadly combats, the empire remains with the survivor. Huber has made the singular observation, that two queens, however inveterate may be their mutual hostility, never actually both destroy each other; and that when, in the course of their contest, they are placed in such a relative position as that each has it in her power to strike a mortal blow on the other with its sting, they suddenly separate, and fly from each other with every appearance of being panic-struck. The final cause of the instinct that prompts this conduct is sufficiently obvious, as, without it, the hive would be altogether deprived of a queen. Bee.

The bees recognise the individual person of their own queen. If another be palmed upon them, they seize and surround her, so that she is either suffocated or perishes with hunger; for it is very remarkable that the workers are never seen to attack a queen-bee with their stings. If, however, more than eighteen hours have elapsed before the stranger queen be introduced, she has some chance of escape. The bees do, indeed, at first seize and confine her, but less rigidly; and they soon begin to disperse, and at length leave her to reign over a hive, in which she was at first treated as a prisoner. If twenty-four hours have elapsed, the stranger will be well received from the first, and at once admitted to the sovereignty of the hive. If a supernumerary queen be introduced into the hive, she is laid hold of by the bees, and presented to the reigning queen, while a ring is formed by the bees, who continue to be spectators, and even promoters of the combat, in which one or other of the queens is destined to perish. Schirach and Reims had imagined that, in these circumstances, the stranger met her death from the hands of the working bees; but this mistake has been rectified by Huber, who gives the account above stated.

Retarded fecundation. If the impregnation of the queen be delayed beyond the twenty-first day of her life, she begins soon after to lay the eggs of drones, and produces no other kind of eggs during the remainder of her life. This very curious and unexpected fact was discovered by Huber, and has been satisfactorily established by his very numerous and varied experiments, although its explanation is perhaps attended with insuperable difficulties. The body of a queen whose impregnation has thus been retarded is shorter than common, and the extremities remain slender, while the first two rings of the abdomen, or those next the thorax, are uncommonly swollen. On dissecting the double ovary, both branches were found to be equally expanded and equally sound, but the eggs were apparently not placed so closely together as in common queens. It was not correctly ascertained whether the queens whose impregnation was retarded laid a number of drone eggs corresponding to the whole number of eggs, both of workers and drones, which they ought to have deposited; but it is certain that they laid a greater number of drone eggs than they ought naturally to have done. On these occasions the instinct of the queen-bee appears to suffer, for she then lays her eggs indiscriminately in large and in small cells, those laid in large cells producing large drones, those in small cells small drones; and she has been known to lay the eggs of drones even in royal cells, some of which are always constructed when the queen begins to lay male eggs. It is curious that the workers were, on these last occasions, deceived, and treated the embryo drones as if they had been truly of the royal brood.

Prolific working bees. One of the most remarkable facts concerning the generation of bees, is the existence occasionally of prolific workers, the discovery of which we owe to Reims. Although it was doubted by Bonnet, its reality has been fully confirmed by the researches of Huber; and it explains what was before unaccountable, the production of eggs in hives absolutely destitute of a queen. It is also remarkable, that the eggs thus produced are always those of drones. The origin of these supplementary queens is accounted for from their having passed the vermicular state in cells contiguous to the royal ones, and from their having, at an early period, devoured some portion of the

stimulating jelly which was destined for the nourishment of the royal brood; and from their ovaria thus receiving a partial development, which renders them susceptible of being impregnated. It is curious that these imperfect queens are still objects of jealousy and animosity to the queen-bee. How they become impregnated has not been ascertained; but the fact of their being productive was a strong confirmation of the truth of Schirach's theory concerning the sexes of bees. Needham, to whom the fact was known, had eluded the force of the argument by pretending that these bees did not belong to the working class, but were real queens of an unusually small size. The supposed absence of ovaria in the working bee was still, indeed, a difficulty which tended to throw some degree of doubt on the correctness of Schirach's doctrine. No person, as Bonnet repeatedly alleges, could suppose that these organs, however minute they might be, had escaped the penetration of Swammerdam, who was unrivalled in his anatomical skill in all that related to insects, and who had bestowed great labour in the examination of the structure of the bee. What had eluded his scalpel and microscope was reserved for the still finer hand and more dexterous dissection of a lady. Miss Jurine, the daughter of the celebrated naturalist of Geneva, has discovered, by adopting a particular method of preparing the object to be viewed, the rudiments of ovaria in the common working bee; she examined a great number, and never failed to find them. Cuvier, in his *Leçons d'Anatomie Comparée*, mentions a suspicion that he had seen some very small oviducts in the working bees, a suspicion which we now find to be completely verified.

Effects of mutilations.

We have next to relate the results of experiments of a more cruel kind, but which illustrate several points in the physiology of these insects. The amputation of the four wings of the queen did not interfere with her laying of the eggs, and the workers did not show her the less attention on account of her being thus mutilated. Of course, if the operation be performed before she is impregnated, she remains barren, since it is necessary for the sexual congress that she should fly out of the hive. The amputation of a single antenna appeared to be productive of no bad consequence of any kind; but the removal of both the antennæ was followed by singular effects. The queen who had suffered this operation ran about in apparent disorder, dropping her eggs at random, and was incapable of directing her trunk with precision to the food that was offered her. At times she appeared desirous of escaping from the hive, and when this was prevented, she returned in a state of delirium, was indifferent to the caresses of the workers, and received another similarly mutilated queen, that was presented to her, without the least symptom of dislike. The workers, on the other hand, received the stranger queen with great respect, although the first still remained in the hive. A third queen, not mutilated, was next introduced; she was very ill received, and immediately detained and kept close prisoner. When the queen, deprived of her antennæ, was allowed to quit the hive, she was followed by none of the workers, and was abandoned to her fate.

Variations in their mode of building.

Bees naturally build from above downwards, but may, by a particular artifice, devised by Huber, be induced to reverse this process. For this purpose a glass hive, with slender laths fixed at the bottom of it, must be provided, and the bees confined in it. They are unable to fasten themselves to the smooth surfaces, and, therefore, establish the foundations of the combs on the wood, and are forced to proceed in a direction opposite to the usual one; in this way Huber was enabled to observe their proceedings. But the readiest mode of inducing them to build in any particular direction is to supply them with portions of ready-made combs, which should be fixed with wires in the proper position; and they will always continue to complete them upon the model presented to them. The hive which Huber recommends is constructed on this principle, consisting of upright frames of a square form, fitted to each other, and of such a size as just to contain each of them a single comb; by separating these, every part of the hive can be laid open and examined with the utmost ease. Féburier has improved upon this construction by changing the shape of the frames from a square to a trapezium, having an acute angle at the summit; a form which allows the moisture that collects at the top to run down the sides more easily than it would do from a flat roof. In this way, any portion of the honey or wax may be removed at pleasure, without hurting or incommoding any one of the bees; and artificial swarms may, at the proper season, be readily procured, by dividing the hive into two portions, and adapting empty frames to each portion.

Enemies of bees.

The wasp and the hornet have long been known as the determined enemies of the bee, committing great ravages among these weaker insects: they attack them individually, but oftener commit their aggressions in large armies, on which occasions numbers perish on both sides. In some parts of America, wasps have multiplied to so great a degree, as to render it impossible to rear bees. Among quadrupeds, the ant-eater occasionally devours them. The bear and the badger overturn the hives, and plunder their contents. Rats and mice are very formidable enemies, as they invade them at all seasons, and especially during their torpid state, when they are incapable of revenging the aggression. The woodpecker may succeed in breaking through the hive, and then speedily destroys all its inhabitants; the swallow, the sparrow, the titmouse, the cuckoo, and the *Merops apiaster*, or bee-eater, and poultry of every kind, prey upon them separately. According to Bosc, they are also food for the shrikes, and for the *Falco apivorus*. Lizards watch for them, and seize them as they alight near the hive. Toads occasionally devour them. They are in some danger from the larger kinds of spiders, and of *Libellulæ*, as also from the *Philanthus apivorus* of Fabricius. But the most insidious and destructive enemy of these insects is the moth; various species of which, particularly the *Phalena mellolcna*, insinuate themselves into the hive, and deposit their eggs unperceived between the cells in such numbers, that the hive is soon overrun with the larvæ, where they are hatched, and the bees are forced to abandon the hive. A new enemy of the same tribe has been lately discovered by Huber, in the *Sphinx atropos*, well known by the name of death's head. Towards the end of autumn, when the bees have filled their magazines, a loud hum is sometimes heard near their habitation, and a multitude of bees come out during the night, and fly about in the utmost confusion. The tumult continues for several hours, and the next morning a number of dead bees are strewed before the hive. On examining the hive, it is found to have been robbed of all its honey, and the bees do not return to it.[1] These effects result from the incursions of the sphinx, which watches its opportunity to introduce itself into the hive during the night, when the bees are depriv-

[1] There appears to be some exaggeration or misconception in this statement of the Genevese observer. The death's head moth is one of the largest of the lepidopterous insects of Europe, and could not possibly effect an entrance into any hive constructed with ordinary care. Nor is it probable that it could consume more than a very small portion of honey, even if it were to obtain admission.

Bee. ed of the advantages of vision, which the sphinx enjoys in greater perfection at this period. By rendering the door-way extremely narrow, so as only to admit a single bee at a time, this accident may be prevented; and it is curious that the bees themselves frequently anticipate this danger, and provide against it by employing, of their own accord, the very same mode of defence. They construct a thick wall, which barricades the entrance, and resembles a regular fortification, with bastions, casemates, and massive gateways. They often, indeed, have recourse to a similar contrivance for protection against the pillaging bees, enabling them to repel the assault with greater effect. At other times, when the danger is less pressing, the inconveniences of so narrow a gateway being strongly felt, they enlarge it by removing the fortification they had built, and do not again construct it unless the appearance of the enemy in the ensuing season should inspire them with fresh alarms. If, on the other hand, the precaution of narrowing the gateway should already have been taken by the cultivator, the bees, feeling themselves secure, spare themselves the unnecessary labour of erecting these walls. This single trait in their history is a sufficient refutation of those theories which ascribe all their actions to the operation of a blind indiscriminating instinct, and would exclude every species of foresight and reflection. (P. M. R.)

In the article APIARY of this work we have already described the leaf and book hives of M. Huber, with the proposed improvements of several other apiarians. The chief objection to some of these is the expense and difficulty of their construction, and the greater degree of attention which they exact on the part of the cultivator. Those made of straw are generally preferred, as being less liable to be overheated by the rays of the sun: they are likewise of easy purchase, from their cheapness; and in winter they exclude the cold better than hives made of other materials. The following is Mr Wildman's account of the structure and general management of his hives:—"My hives are seven inches in height and ten in width. The sides are upright, so that the top and bottom are of the same diameter. A hive holds nearly a peck. In the upper row of straw there is a hoop of about half an inch in breadth, to which are nailed five bars of deal, full a quarter of an inch in thickness and an inch and quarter wide, and half an inch asunder from one another; a narrow short bar is nailed at each side, half an inch distant from the bars next them, in order to fill up the remaining parts of the circle; so that there are in all seven bars of deal, to which the bees fix their combs. The space of half an inch between the bars allows a sufficient and easy passage for the bees from one comb to another. In order to give great steadiness to the combs, so that, upon moving the hive, the combs may not fall off, or incline out of their direction, a stick should be run through the middle of the hive, in a direction directly across the bars, or at right angles with them. When the hives are made, a piece of wood should be worked into the lower row of straw, long enough to allow a door for the bees, of four inches in length, and half an inch in height.

"The proprietor of the bees should provide himself with several flat covers of straw, worked of the same thickness as the hives, and a foot in diameter, that so it may be of the same width as the outside of the hives. Before the cover is applied to the hive, a piece of clean paper, of the size of the top of the hive, should be laid over it; and a coat of cow-dung, which is the least apt to crack of any cement easily to be obtained, should be laid all round the circumference of the hive. Let the cover be laid upon this, and made fast to the hive with a packing-needle and pack-thread, so that neither cold nor vermin may enter.

"Each hive should stand single on a piece of deal or other wood, somewhat larger than the bottom of the hive. That part of the stand which is at the mouth of the hive should project some inches for the bees to rest on when they return from the field. This stand should be supported upon a single post, two and a half feet high, to which it should be screwed very securely, that high winds or other accidents may not blow down both stand and hive. A quantity of soot mixed with barley chaff should be strewed on the ground round the post, which will effectually prevent ants, slugs, and other vermin, from rising up to the hive. The soot and chaff should from time to time be renewed as it is blown or washed away, though, as it is sheltered by the stand, it remains a considerable time, especially if care be taken that no weeds rise through it. Weeds, indeed, should not be permitted to rise near the hive, for they may give shelter to vermin which may be hurtful to the bees. Bee.

"The stands for bees should be four yards asunder, or, if the apiary will not admit of so much, as far asunder as may be, that the bees of one hive may not interfere with those of another hive, as is sometimes the case when the hives are near one another, or on the same stand; for the bees, mistaking their own hives, light sometimes at the wrong door, and a fray ensues, in which one or more may lose their lives."

He further directs, that whoever intends to construct an apiary should purchase a proper number of hives at the latter part of the year, when they are cheapest. These should be full of combs, and well stored with bees. The purchaser should also examine the combs, with a view to ascertain the age of the hives. The combs of the season are white; those of the former year are of a darkish yellow; and where the combs are black, the hive should be rejected, because when old they are more subject to the attacks of vermin and other accidents. If the requisite number of hives have not been purchased in the autumn, it will be necessary to remedy this neglect as soon as the severity of the cold has passed in spring. At this season, according to Mr Wildman, bees which are in good condition will go into the fields early in the morning, return well laden, enter boldly, and will seldom leave their home in bad weather. They are alert on the least disturbance; and we may judge of their strength by the loudness of their humming. The summer is not an advisable season for purchasing bees, because the heat of the weather softens the wax, and renders the combs liable to break and give way, if they are not well secured in the interior. The honey, too, being thinner than at other times, is more apt to run from the cells, which not only occasions a loss of the material, but daubs, and possibly destroys, the bees.

Mr Wildman's feats in the handling of these irritable and pugnacious creatures have been the frequent subject of surprise. As it is often of consequence to be able to regulate the settling of a swarm, we shall here subjoin his method in his own words. "Long experience has taught me, that as soon as I turn up a hive, and give it some taps on the sides and bottom, the queen immediately appears to know the cause of this alarm, but soon retires again among her people. Being accustomed to see her so often, I readily perceive her at first glance; and long practice has enabled me to seize her instantly with a tenderness that does not in the least endanger her person. This is of the utmost importance, for the least injury done to her brings immediate destruction to the hive, if you have not a spare queen to put in her place, as I have too often experienced in my first attempts. When possessed of her, I can without injury to her, or exciting that degree of resentment that may tempt her to sting me, slip her into my other

Bee. hand, and, returning the hive to its place, hold her there, till the bees, missing her, are all on wing, and in the utmost confusion. When the bees are thus distressed, I place the queen wherever I would have the bees to settle. The moment a few of them discover her, they give notice to those near them, and those to the rest, the knowledge of which soon becomes so general, that in a few minutes they all collect themselves round her, and are so happy in having recovered this sole support of their state, that they will long remain quiet in their situation. Nay, the scent of her body is so attractive of them, that the slightest touch of her along any place or substance will attach the bees to it, and induce them to pursue any path she takes." This was the only witchcraft used by Mr Wildman, and is that alone which is practised by others who have since made similar exhibitions.

In the management of bees a great deal must of course depend on supplying them with an abundant pasture. A rich corn country is well known to be to them as a barren desert during a great portion of the year. Hence the judicious practice of shifting them from place to place according to the circumstances of the season. It was the advice of Celsus, that after the vernal pastures were consumed, bees should be transported to places abounding with autumnal flowers; and it was in accordance with such advice that they were annually carried in ancient times from Achaia to Attica, and from Eubœa and the islands of the Cyclades to Scyrus. In Sicily, also, they were brought to Hybla from other parts of the island. So also in our own country the people of the lowlands, as soon as the "bright consummate flowers" of summer are on the wane, dispatch their hives in cart loads to the blooming heather of the mountain pastures, where a never-ending wilderness of sweets is spread before them. It is indeed to be regretted that our moorlands, in this respect, are so much more neglected than they ought to be. The very air of the highland hills is often redolent with the rich perfume, while here and there a solitary bee is seen or heard labouring with wearied wing among the inexhaustible stores of nature, and scarcely able to regain its lonely shieling in the distant vale. When we consider the poverty of our mountaineers, and their frequent want of occupation, it is the more to be lamented that so easy a source of emolument should lie open to them in vain. It has been calculated that the pastures of Scotland could maintain as many bees as would produce 4,000,000 pints of honey and 1,000,000 pounds of wax; and were these quantities tripled for England and Ireland, the produce of the British empire would be 12,000,000 pints of honey, and 3,000,000 pounds of wax per annum. If we allow five shillings per pint for the honey and one shilling and sixpence per pound for the wax, we have an annual produce in money of L.3,225,000. But, in consequence of the present neglect of this branch of rural economy, we pay every year a large sum to foreign nations for articles which we could raise ourselves, with scarcely any outlay either of capital or time.

We learn from Pliny that the practice of removing bees from place to place was frequent in the Roman territories. "As soon," says he, "as the spring food for bees has failed in the valleys near our towns, the hives of bees are put into boats, and carried up against the stream of the river in the night, in search of better pasture. The bees go out in the morning in quest of provisions, and return regularly to their hives in the boats, with the stores they have collected. This method is continued till the sinking of the boats to a certain depth in the water shows that the hives are sufficiently full; and they are then carried back to their former homes, where their honey is taken out of them." And this is still the practice of the Italians who live near the banks of the Po, the river which Pliny instanced particularly in the passage above quoted. Bee.

M. Maillet relates, in his description of Egypt, that, in "spite of the ignorance and rusticity which have got possession of that country, there yet remain in it several footsteps of the industry and skill of the ancient Egyptians. One of their most admirable contrivances is, their sending their bees annually into distant countries, in order to procure them sustenance there, at a time when they could not find any at home; and their afterwards bringing them back, like shepherds who should travel with their flock, and make them feed as they go. It was observed by the ancient inhabitants of Lower Egypt, that all plants blossomed, and the fruits of the earth ripened, above six weeks earlier in Upper Egypt than with them. They applied this remark to their bees; and the means then made use of by them to enable these usefully industrious insects to reap advantage from the more forward state of nature there, were exactly the same as are now practised for the like purpose in that country. About the end of October, all such inhabitants of Lower Egypt as have hives of bees, embark them on the Nile, and convey them up that river quite into Upper Egypt; observing to time it so that they arrive there just when the inundation is withdrawn, the lands have been sown, and the flowers begin to bud. The hives thus sent are marked and numbered by their respective owners, and placed pyramidically in boats prepared for the purpose. After they have remained some days at their farthest station, and are supposed to have gathered all the wax and honey they could find in the fields within two or three leagues around, their conductors convey them in the same boats two or three leagues lower down, and there leave the laborious insects as long time as is necessary for them to collect all the riches of this spot. Thus the nearer they come to the place of their more permanent abode, they find the productions of the earth, and the plants which afford them food, forward in proportion. In fine, about the beginning of February, after having travelled through the whole length of Egypt, gathering all the rich produce of the delightful banks of the Nile, they arrive at the mouth of that river, towards the ocean, from whence they set out, and from whence they are now returned to their several homes; for care is taken to keep an exact register of every district from whence the hives were sent in the beginning of the season, of their numbers, of the names of the persons who sent them, and likewise of the mark or number of the boat in which they were placed."

In many parts of France floating bee-houses are very common. They have on board one barge three score or a hundred bee-hives, well defended from the inclemency of an accidental storm. With these the owners suffer themselves to float gently down the river, the bees continually choosing their flowery pasture along the banks of the stream; and thus a single floating bee-house yields the proprietor a considerable income.

They have also a method of transporting their bees by land, well worth our imitation in many parts of this kingdom. Their first care is to examine those hives, some of whose honeycombs might be broken or separated by the jolting of the vehicle; they are then made fast one to the other, and against the sides of the hive, by means of small sticks, which may be disposed differently as occasion points out. This being done, every hive is set upon a packing-cloth, or something like it, the threads of which are very wide; the sides of this cloth are then turned up and laid on the outside of each hive, in which state they are tied together with a piece of small packthread wound several times round the hive. As many hives as a cart built for the purpose will hold are after-

Bee || Beech Oil.

wards placed in the vehicle. The hives are set two and two, the whole length of the cart. Over these are placed others, which make as it were a second story or bed of hives. Care is taken in this stowage not to let one hive stop up another, it being essentially necessary for the bees to have air; and it is for this reason they are wrapped up in a coarse cloth, the threads of which have been wove very wide, in order that the air may have a free passage, and lessen the heat which these insects raise in their hives, especially when they move about very tumultuously, as often happens in these carts. Those used for this purpose in Yevre hold from thirty to forty-eight hives. As soon as all are thus stowed, the caravan sets out. If the season is sultry, they travel only in the night; but a proper advantage is taken of cool days. These caravans do not travel fast. The horses must not be permitted even to trot: they are led slowly, and along the smoothest roads. When there are not combs in the hives sufficient to support the bees during their journey, the owner takes the earliest opportunity of resting them wherever they can collect the materials for wax. The hives are taken out of the cart, then set upon the ground, and after removing the cloth from over them, the bees go forth in search of food. The first field they come to serves them as an inn. In the evening, as soon as they are all returned, the hives are shut up; and being placed again in the cart, they proceed on their journey. When the caravan has arrived at the journey's end, the hives are distributed in the gardens, or in the fields adjacent to the houses of different peasants, who, for a very small reward, undertake to look after them. Thus it is that, in such spots as do not abound in flowers at all seasons, means are found to supply the bees with food during the whole year.

These instances of the great advantages which attend the shifting of bees in search of pasture afford an excellent lesson to many places in this kingdom: they direct particularly the inhabitants of the rich vales, where the harvest for bees ends early, to remove their stocks to places which abound in heath; this plant continuing in bloom during a considerable part of autumn, and yielding great abundance of food to bees. Persons in the neighbourhood of hills and mountains will save the bees a great deal of labour, by also taking the advantage of shifting their places of abode.

The degree of cold which bees can endure has not been ascertained, though it is no doubt considerable. They survive the winter in many cold parts of Russia, in hollow trees, without any attention being paid to them; and their hives are frequently made of the bark of trees, which does not afford a very complete protection from the effects of frost. Many hives which are thought to die of cold in winter die in reality of famine, when a rainy summer and cold autumn have prevented their laying in a sufficient store of provisions. The hives should therefore be carefully examined in the after-part of the season, and the amount of food ascertained. Mr White judiciously observes, that bees which stand on the north side of a building whose height intercepts the sun's beams all the winter will waste less of their provisions than others which stand in the sun; for, coming forth seldom, they eat little, and yet are as forward in the spring to work and swarm as those which had twice as much honey left with them the preceding autumn. The owner ought, however, to examine their condition in the course of the winter, and if he finds that, instead of being clustered between the combs, numbers have fallen to the bottom of the hive, it should immediately be shifted to a warmer place.

Bee || Beechey.

In regard to the destruction of bees, it has been observed that no true lover of these industrious insects ever lighted the fatal match without concern. A simple method of obtaining possession of a portion of their store is the following: Uncover the hole in the upper centre of a flat-topped straw hive or box, and place a glass vessel over it in such a way that no bee can get either in or out except by the ordinary opening of the lower hive. The glass hive must be covered with an empty hive or with a cloth, that too much light may not prevent the bees from working. As soon as they have filled the straw hive or box, they will begin to work up into the glass hive. Mr Thorley junior informs us, that he himself has had one of these glass hives filled by the bees in thirty days in a fine season; and that it contained 38 pounds of fine honey. When the glass is completely filled, slide a tin plate between it and the hive or box, so as to cover the passage, and in half an hour the glass may be taken off with safety. What few bees remain in it will readily go to their companions. He has added a glass window to his straw hives, in order to see what progress bees make; which is of some importance, especially if one hive is to be taken away whilst the season still continues favourable for their collecting honey; for when the combs are filled with honey, the cells are sealed up, and the bees forsake them and reside mostly in the hive in which their works are chiefly carried on. Observing also that the bees were apt to extend their combs through the passage of communication in the upper hive, whether glass or other, which rendered it necessary to divide the comb when the upper hive was taken away, he now puts in that passage a wire screen or netting, the meshes of which are large enough for a loaded bee to go easily through them. This prevents the joining of the combs from one box to the other, and consequently obviates the necessity of cutting them, and of spilling some of the honey, which, running down among a crowd of bees, used before to incommode them much, it being difficult for them to disencumber their wings.

Chloroform has been employed with success in uniting swarms and artificial swarming, as well as for the purpose of extracting the honey from the hive. A quarter of an ounce of chloroform, in a saucer covered with a perforated card or with wire-gauze, is to be placed on the board of the hive, and all apertures to be carefully closed. In about half a minute the bees will be completely under its influence; and on the admission of air, after a lapse of fifteen or twenty minutes they will revive and soon recover the use of their wings.

We shall conclude by observing, that the honey-bee (*apis mellifica*) is supposed to be of Asiatic origin. They were imported from Europe to America, where they are now found wild in great numbers, and at a vast distance from human habitations. An excellent treatise on the "Honey Bee," its natural history, physiology, and management, was published in 1827 by Dr Edward Bevan. It contains some of the best practical remarks on this subject with which we are acquainted; and gives a fair account of the labours of his predecessors, Reaumur, Hunter, Huber, Keys, Vicat, and Dunbar, with a few remarks of the more noted authors who have treated of bees. (J. W.)

BEE-EATER (*Merops*). See ORNITHOLOGY, *Index*.

BEECH, see PLANTING; TIMBER; STRENGTH OF MATERIALS; and *Index*.

BEECH-MAST, the fruit or nuts of the beech-tree, used for fattening hogs, deer, and other animals. It has sometimes proved a useful substitute for bread, as experienced at Chios during a memorable siege.

BEECH OIL, an oil expressed from the mast of the beech-tree. It is in common use in Picardy, and in other parts of France, instead of butter; but it is said to be unwholesome.

BEECHEY, SIR WILLIAM, R.A., an eminent portrait-painter, born at Burford in December 1753, was originally bred as a conveyancer; but a strong love for painting induced him to become a pupil at the Royal Academy in 1772. He soon became noted for the spirit of his attitudes and the clearness of his colouring. His finest production is a review

of cavalry, a large composition in the foreground of which he introduced portraits of George III., the Prince of Wales, and the Duke of York, surrounded with a brilliant staff on horseback. It was painted in 1793, and obtained for the artist the honour of knighthood, and the rank of R.A. The earlier portraits of Beechey were carefully drawn and well finished, but in his later days the extent of his employment rendered him less careful in his design. But a series of his cartoon sketches in the Royal Institution of Liverpool shows that his skill in drawing was very considerable. He died in January 1839, at the advanced age of eighty-six. (T. S. T.)

BEEDER, in Southern India, a town of Hyderabad, or the dominions of the Nizam, is situate on an elevated tableland 2359 feet above the level of the sea. This place is fortified with a stone wall about six miles in circumference, a dry ditch, and many round towers. The town is much decayed, but the remains of many old buildings are still visible. Before the Mahometan invasion it was the seat of a Hindu sovereignty; but upon the revolt of the Deccan in 1347 against the supremacy of Delhi, Beeder was selected as the seat of government of the newly-founded Mahometan kingdom of Bahmani. Towards the close of the following century, upon the dismemberment of the territories of which it had formed the capital, Beeder, with an adjacent district, rose to the dignity of a separate state, and though of inconsiderable dimensions contrived to maintain its independence until the commencement of the seventeenth century, when it merged into the neighbouring kingdom of Ahmednuggur. In 1636 Shah Jehan, Emperor of Delhi, invaded the Deccan, and subjected Ahmednuggur to tribute; but in the anarchy and confusion which prevailed during the decay of the Mogul empire, the town and territory composing the former principality of Beeder fell to the Nizam, and were by him incorporated with the present dominions of Hyderabad. Distant N.W. from Hyderabad 75 miles. Lat. 17. 53. Long. 77. 36. (E. T.)

BEEF, the flesh of an ox, bull, or cow. According to Dr Cullen, beef, though of a more firm texture and less soluble than mutton, is equally alkalescent, perspirable, and nutritious.

BEEF-EATER (from the French *beauffetier*), a yeoman of the royal guard. See APPELLATION.

BEEF-EATER, *Buphaga*. See ORNITHOLOGY.

BEELE, a kind of pick-axe used by miners.

BEELZEBUL, (Βεελζεβουλ, *dominus stercoris, i.e.* metaphorically *Lord of idolatry*), the name given by the Jews to the prince of the demons. It is incorrectly written *Beelzebub* in the New Testament. See BAALZEBUB, and PHILISTINES.

BEEMAH, a river of Hindustan which rises in the mountains to the north of Poonah, and flowing S.E., passes within thirty miles of that city. It is one of the principal tributaries of the Krishna, which it joins near the town of Kadloor in the dominions of the Nizam. The Hindus regard it as a sacred river. The length of its course is about 510 miles.

BEER, a town of Asiatic Turkey. See BIR.

BEER. See BREWING.

BEERALSTON, a borough-town in the county of Devon, hundred of Roborough, and parish of Beerferris, near the confluence of the Tavy with the Tamar, 215 miles from London. It formerly returned two members to parliament, who were chosen by the holders of ancient burgages; and as there were few houses, the elections of members were held under a large tree. Near it are four lead mines, which occasionally yield a small quantity of silver. Pop. of parish in 1851, 3401.

BEER REGIS, a market-town of Dorset, 112 miles from London. Near it is a hill which was formerly a Roman encampment, where a great fair is annually held on 18th September and five following days. The church is a handsome edifice. Pop. in 1851, 1242.

BEERSHEBA, or BERSABE, a place in the southernmost part of Canaan, celebrated for the sojourn of the patriarchs. This name, signifying the *well of the oath*, was bestowed in allusion to the covenant there made between Abraham and Abimelech. It is mentioned by Eusebius and Jerome, in the fourth century, as a large village. The well of Abraham, or rather two wells, lie 27 miles S.E. from Gaza, and still afford an abundant supply of pure water.

BEES, ST, a parish of England, county of Cumberland, on the sea-coast, comprising the town of Whitehaven and the village of St Bees. Pop. (1851) 23,486. St Bees is a place of great antiquity. The parish church, a cruciform building with a massive tower, was once a part of the monastery of St Bega, founded about A.D. 650. The chancel is occupied by the theological college, established in 1817 by Bishop Law. The grammar-school, founded in the sixteenth century by Archbishop Grindall, has several exhibitions and fellowships both at Oxford and Cambridge. Pop. of township (1851) 971.

BEESTINGS, or BIESTINGS (German, *biestmilch*), the first milk taken from a cow after calving. It seems to be intended by nature to cleanse the young animal from the recrements gathered in its intestines during uterogestation. The first milk of women possesses a similar quality; and hence the natural inference that a mother should suckle her own child, rather than commit it to a nurse whose first milk is gone.

BEET or BETA, a well-known genus of plants. The common beet, *Beta vulgaris*, a variety of the red beet, has long been cultivated as a food for cattle, and is also used for the table as a pickle. It was introduced for this purpose in the latter part of the last century from Germany, where it is known by the name of *mangel-wurzel*. See AGRICULTURE. The variety termed *white beet* is smaller than the former, and has chiefly been cultivated on a large scale for the formation of sugar from its root. The chemical elements of beet-root sugar are expressed *atomically* thus:—C_{12}, H_9, O_9 + 2 HO, or twelve atoms of carbon, nine of hydrogen, nine of oxygen, and two of water. The largest extract of pure sugar from beet-root in Belgium was formerly three per cent., but is now six per cent., and is capable of further increase by improvement in the process of manufacture. The cultivation of beet-root was especially fostered in France by Napoleon, whose policy it was to encourage everything that tended to render the Continent independent of Britain, then in possession of the chief sugar colonies. It is only within a comparatively recent period, however, that the manufacture of beet-root sugar in Europe has assumed any degree of importance, the total quantity produced in 1828 not exceeding 7000 tons, while in 1851 it was estimated at not less than 180,000 tons. We subjoin a few statistics relative to the increasing importance of this manufacture from *The Economist* (Nos. 431 and 432, Nov. 29th, and Dec. 26th 1851). The quantity of beet-root sugar annually produced in France is 60,000 tons, or fully one-half of the entire consumption. Though now subject to a higher duty than colonial cane sugar, it is considered probable that very shortly it will exclude foreign sugar from the French market altogether. The production of beet-root sugar in Belgium also is rapidly on the increase, the quantity produced in 1850 being 7000 tons, or half the entire consumption of that kingdom. This had increased in 1851 to 10,000 tons, while of foreign cane sugar only 4000 tons were imported. In Germany it has made similar progress. In 1848 the quantity produced was 26,000 tons, which had risen in 1851 to 43,000, with a corresponding decrease in the imports of foreign sugar. Of 85,000 tons of sugar estimated to have been consumed in Russia, 35,000 tons were beet-root sugar. In Austria also the production of this article increased from 8000 tons in 1848, to 15,000 tons in 1851, while the consumption of cane sugar had sunk from 32,000 to 25,000 tons. This subject, in all its bearings, will be found fully discussed under the head SUGAR.

Beethoven.

BEETHOVEN, LUDWIG VAN, one of the greatest pianists and musical composers of modern times, was born on the 17th December 1770, at Bonn, on the Rhine. Beethoven's father, Theodore van Beethoven, a native of Maestricht, was a tenor in the Elector of Cologne's chapel, and had four sons and one daughter. The subject of this article was the second son. His musical genius showed itself very early. When five years old he began the study of music under Vander Eden, the court organist. In 1782 he was placed under C. G. Neefe, the successor of Eden, who set his pupil to study the works of J. S. Bach and Handel. Beethoven's early powers of execution and of improvisation on the piano astonished every hearer. In 1793 he began his serious studies of composition under Albrechtsberger at Vienna. His exercises in harmony and counterpoint written under that master were published at Paris in 1833, in 2 vols. small folio, with protrait, &c.; and are very curious as exhibiting the perpetual conflict between Beethoven's imagination and his perseverance in the hard and dry studies prescribed to him. He began these too late in life to be able to render their forms quite subject to his will when he employed them in his compositions. Some of his instruction in vocal composition was derived from the celebrated Italian composer Salieri.

It appears that during a great part of his life he suffered from deafness, which had become almost total in his twenty-eighth year. In his will, dated 1802, his expressions of wretchedness under this infliction are very strong. He says that his deafness occasioned him such anguish of mind that he was often tempted to commit suicide, but that his art restrained him. There is something very affecting in all this, which reminds one of Milton's frequent and touching allusions to the miseries of blindness.

Beethoven tells us that his unhappy deafness, occasioned by the ignorance and mismanagement of a surgeon, was the cause of his withdrawing himself from society, and leading a solitary and miserable life. He speaks in terms of the deepest grief of the many privations to which the loss of his hearing subjected him;—his incapacity of enjoying audible music, and his inability to maintain social intercourse by means of speech. The feeling of his irreparable loss seems to have haunted him perpetually like some hideous phantom. Doubtless he often felt most deeply what Dante has so well expressed in the bitterness of his recollections:—

> ———"Nessun maggior dolore
> Che ricordarsi del tempo felice
> Nella miseria."

The spirited sketch given by Mr Russell,[1] from his own observation, of Beethoven's appearance, and manners, and musical performance, is quite consistent with what the writer of this article has heard from other persons. Mr Russell tells us (*Tour in Germany*, vol. i. p. 277), "though not an old man, he (Beethoven) is lost to society, in consequence of his extreme deafness, which has rendered him almost unsocial. The neglect of his person which he exhibits gives him a somewhat wild appearance. His features are strong and prominent; his eye is full of rude energy; his hair, which neither comb nor scissors seem to have visited for years, overshadows his broad brow in a quantity and confusion to which only the snakes round a Gorgon's head offer a parallel. His general behaviour does not ill accord with this unpromising exterior. Except when he is among his chosen friends, kindliness or affability are not his characteristics. The total loss of hearing has deprived him of all the pleasure which society can give, and perhaps soured his temper."

"He has always a small paper book with him, and what conversation takes place is carried on in writing. In this too although it is not lined, he instantly jots down any musical idea which strikes him." Mr Russell heard him play, and says that, from his deafness, "when playing very *piano*, he often does not bring out a single note, yet he hears it himself in the 'mind's ear.' While his eye and the almost imperceptible motion of his fingers show that he is following out the strain in his own soul through all its dying gradations, the instrument itself is actually as dumb as the musician is deaf."[2]

Beethoven died at Vienna on the 26th March 1827, in the fifty-seventh year of his age. His funeral took place on the 29th, and was attended by a great number of poets, literary men, and musicians, who attended as mourners, besides a vast concourse of the people of Vienna. His body was interred in the churchyard of Friedhofe, a village about two English miles from Vienna, a favourite resort of his, where he is said to have passed many solitary hours in meditation and composition. The churchyard rises gradually from the road, and Beethoven's grave is situated about half-way up, close to the wall, on the left-hand side. Against the wall was placed a marble slab, of which a print has been published, having merely the word "Beethoven" in carved gilt letters, but surmounted by the image of a lyre and a head crowned with rays, and at the top a butterfly with expanded wings, the symbol of resurrection and immortality. Twenty years afterwards a statue of this illustrious composer was erected in Bonn, his native place.

With regard to Beethoven's abilities as a pianoforte player, the opinion of Mr J. B. Cramer, one of the greatest masters of that instrument, may be sufficient. Mr Cramer described him as "by no means a *finished* or very *delicate* player, but a giant in respect of command of ideas and energy of style." "His extemporaneous playing," Mr Cramer adds, "is the most magnificent I ever heard." Signor Dragonetti concurred in this opinion.

As a composer Beethoven stands in the foremost rank. He possessed a powerful, inventive, and original mind. In respect of regularity of design, purity of harmonic combination, and skilful management of all his materials, he is, generally speaking, inferior to Haydn and Mozart. But still, all his best compositions are pervaded by an enthusiastic spirit of inspiration, a wild and masculine energy, relieved by frequent touches of tender beauty and melancholy, which stamp the superior genius of the man, and may, perhaps, be said to render his music analogous in character to the poetry of Dante. His earlier works and those of the second period of his artistic development are his best. His deafness may in a great measure account for the dry, crude, and unmelodious style of many of his later works. In vocal composition he was not in general greatly successful. Still, in his "Fidelio" there are fine things; and his *scena ed aria*, "Ah perfido! spergiuoro!" and his canzonet, "Adelaide," are truly exquisite. The latter is modelled upon Haydn's fine canzonet, "O tuneful voice!"

In 1840 A. Schindler published in Germany a life of Beethoven, containing much silly gossip and some misstatements. A true life of the great musician has yet to be written. (G. F. G.)

BEETLE, a term applied to most insects belonging to the order *Coleoptera*. See ENTOMOLOGY.

BEETLE also denotes a wooden instrument for driving piles, &c.: likewise called a *stamper*, and by pavers a *rammer*.

BEEVES (old plural of *beef*), a general name for oxen.

BEFORT, or BELFORT, a second-class fortified town of France, in the department of Upper Rhine, and capital of an arrondissement of the same name, is situated on the Savoureuse, 38 miles S.S.W. of Colmar. It contains a handsome church, a college, and a public library of 20,000 volumes; and has several iron foundries and iron-wire factories. Pop. (1851) 5274. The arrondissement of the same name

[1] Russell's *Tour in Germany*, &c. in 1820-21-22. 2 vols. 8vo. Edinb. 1824.

[2] *Ibid.* vol. i. pp. 277, 278, 299.

Bega || Behaban.

contains 9 cantons, and 192 communes. Pop. (1851) 132,591.

BEGA, CORNELIUS, a painter of landscapes, cattle, and conversazioni, was born at Haerlem in 1620, and studied painting under Adrian Ostade. Falling into a dissipated way of life, he was disinherited by his father, for which reason he changed his paternal name, which was Begeyn, and took that of Bega; hence his early pictures are marked with the former name, his subsequent works with the latter. Bega, at the age of forty-four, died of the plague, having taken the infection from his mistress, whom he attended with unceasing devotion till the last hour of her life.

BEGARELLI, ANTONIO, an eminent modeller in clay, was a native of Modena. He was born A.D. 1498, and died in 1565. Begarelli is praised by Vasari for the fine air of his heads, his beautiful drapery, exquisite proportions, and his imitations of marble. It is said that Michael Angelo on seeing the works of this artist exclaimed, "If this clay were to become marble, alas for the ancient statues!" His works at Modena and elsewhere are very numerous. (Lanzi, *Stor. Pitt.* iv. 29.)

BEGGAR. See POOR-LAWS.

BEGLERBEG, or BEGLIERBEY, (*i.e. Lord of lords,*) in the Turkish dominions is the title of a high officer, the governor of a province, and next in dignity to the grand vizier. He has under him several beys, agas, &c., and his province is called a beglerbeglik.

BEGUARDS, or BEGHARDS, religionists of the third order of St Francis in Flanders. They were established at Antwerp in the year 1228, and took St Begghe for their patroness, from whom they derived their name. On their first institution they employed themselves in making linen cloth, each supporting himself by his own labour, and were united only by the bonds of charity, without having any particular rule. But when Pope Nicholas IV. had confirmed that of the third order of St Francis in 1289, they embraced it the year following, and were greatly favoured by the dukes of Brabant, particularly John II. and John III., who exempted them from all contributions and taxes. In the year 1425 they began to live in common, and in 1467 made solemn vows, after having taken the habit of the Terciaries of Liège, religionists of the third order of St Francis; and in 1472 they became subject to the general of the congregation of Zepperen in the diocese of Liège, to which they were united by Pope Sixtus IV. But Innocent X. having, in 1650, suppressed the general of the congregation of Zepperen, all the convents of the third order of St Francis, in the dioceses of Liège, Malines, and Antwerp, were submitted to the visitation, jurisdiction, and correction of the general of Italy, and erected into a province under the title of "the province of Flanders." (See Mosheim, *De Beghardis et Beguinabus Commentatio*, Leipz. 1790.)

BEGUINES, a congregation of female religionists or nuns, founded either by St Begghe or by Lambert le Begue, who died about the end of the twelfth century. They were originally established at Liège, and afterwards at Neville. From this last settlement sprang the great number of Beguines, which spread over all Flanders, and thence passed into Germany, where some of these religionists fell into extravagant errors; persuading themselves that it was possible, in the present life, to arrive at impeccability and a clear view of God. The council of Vienna condemned these errors, and abolished the order of Beguines, permitting such of them, however, as continued in the true faith to live in chastity, either with or without vows; under cover of which permission the decree of the council was evaded, and communities of Beguines spread throughout all Flanders.

BEHABAN, a town of Persia, and capital of a mountainous district. It is pleasantly situated in the middle of a valley which is of considerable extent, highly cultivated, and watered by the rivers Zab and Jerahi. The walls are about three miles in circumference. It is said to contain about 10,000 inhabitants, and is the seat of a governor, whose palace is at the north-west corner of the town. It is 153 miles from Shiraz, from which it is separated by a mountainous country, entirely uninhabited, and infested by banditti.

Beheading || Behemoth.

BEHEADING, a capital punishment in which the head is severed from the body by the stroke of an axe, a sword, or some other instrument.

Beheading, called *decollatio*, was a military punishment among the Romans. The head of the culprit was laid on a *cippus* or block placed in a pit dug for the purpose beyond the *vallum*, and near the *porta decumana;* and preparatory to the stroke, he was tied to a stake and whipped with cords. In the early ages the blow was given with an axe, but in after times with a sword, which was thought the more reputable manner of execution. In England decapitation is a punishment reserved for the nobility, as was formerly the case in France, being reputed less derogatory to their rank than hanging, which is the punishment inflicted on ordinary criminals.

In Scotland, beheading was anciently performed by an edged instrument called the *maiden*, consisting of a vertical frame with a sharp and heavily loaded axe or knife-edged iron, which in descending chopped off the head. It was introduced into this country by the Regent Morton, who, as in several similar instances, was himself the first that suffered by it. This instrument has been preserved, and may still be seen in the museum of the Society of Scottish Antiquaries. The *guillotine*, so called from the name of its inventor M. Guillotin, a physician, who is also said to have lost his head by his own contrivance, is an instrument somewhat analogous to the *maiden*, with this exception, that the edge of the knife descends obliquely, and thus the head is severed more instantaneously. In France, beheading is an ordinary capital punishment for great crimes, and the guillotine, notwithstanding all the revolutionary horrors associated with it, is still the instrument by which decollation is performed.

BEHEM, MARTIN, a celebrated geographer and navigator, born at Nurnberg about 1436. He entered into the service of Portugal in 1479, and in 1484 sailed in the fleet of the great captain Diego Cam, which was sent to explore the western coast of Africa. In 1485 he returned to Lisbon, where, on account of his scientific services and charts, the honour of knighthood was bestowed on him by the king, with splendid ceremony. He married the daughter of Job Huester, at Fayal, in 1486. For several years after he was employed in the construction of maps and charts at Lisbon, where he is said to have met Columbus. In the year in which that celebrated navigator sailed to discover the New World, Behem visited his native city, where he resided a year, and constructed a terrestrial globe, some fortunate conjectures in which have been made the foundation of an erroneous theory as to his share in transatlantic discovery, He afterwards resided chiefly at Fayal; but died at Lisbon in 1506, leaving no monuments of his science except this globe, and various maps and charts. The utter silence of the Portuguese government as to his supposed share in the discoveries of Columbus, is sufficient evidence that Behem had no claim to that honour. (T. S. T.)

BEHEMOTH (בהמות, Job xl. 15; in Coptic, according to Jablonski, *Pehemont*) is regarded as the plural of behemah, בהמה, but commentators are by no means agreed as to its true meaning. A number of learned men, with Bochart and Calmet at their head, understand the word in the singular number as a specific name denoting the hippopotamus, seeking to prove, by somewhat forced interpretations of the beautiful poetical allusions in Job xl. 15–24, the exactness of the description when compared with the species, which, however, in some respects is more applicable to the

Behmen ‖ Behring's Strait.

elephant, while in others it is equally so to both animals. Hence the term behemoth, taken intensely (for in some places it is admitted to designate cattle in general), may be assumed to be a poetical personification of the great Pachydermata, or even Herbivora, wherein the idea of hippopotamus is predominant. This view accounts for the ascription to it of characters not truly applicable to one species.

BEHMEN, JACOB. See BOEHM.

BEHN, APHRA, an authoress of some celebrity, born of a good family in the city of Canterbury in the reign of Charles I. Her father, whose name was Johnson, having received the appointment of lieutenant-general of Surinam, proceeded to the West Indies, taking with him his whole family. Mr Johnson died on the voyage; but his family reached Surinam, and resided there for some years. Here Aphra learned the history, and acquired a personal knowledge, of the American prince Oroonoco and his beloved Imoinda, whose adventures she has related in her novel of that name, and which Southerne afterwards made use of in one of his tragedies.

On her return to London she became the wife of Mr Behn, a merchant of Dutch extraction residing in that city. The wit and abilities of Mrs Behn having brought her into high estimation at court, Charles II. employed her to transact some affairs of importance abroad during the Dutch war. For this purpose she went to Antwerp, where by her intrigues and gallantries she so far penetrated into the secrets of state as to accomplish the objects of her mission; and in the latter end of 1666, by means of the influence she had gained over one Vander Albert, she wormed out of him the design formed by De Ruyter, in conjunction with the family of the De Wits, of sailing up the Thames and burning the English ships in their harbours. This she communicated to the English court; but although the event proved her intelligence to have been well founded, it was at the time disregarded;—which circumstance, together with the disinclination shown to reward her for her services, determined the lady to drop all further thoughts of political affairs; and during the remainder of her stay at Antwerp she gave herself up entirely to the gaiety and gallantries of the place. In her voyage home to England she narrowly escaped death, the vessel in which she sailed having foundered, but fortunately within reach of aid.

From this period she devoted her life entirely to pleasure and the muses. Her works are numerous, and all of them are of a lively and amatory character. In her dramatic pieces the plots are full of action and ingenuity, and the dialogue sparkles with wit; but, in common with the licentious taste of the time, they are interlarded with the most indecent scenes and expressions. This singular woman died on the 16th of April 1689, and was interred in the cloisters of Westminster Abbey.

BEHRING'S ISLAND, the most westerly of the Aleutian group, in the North Pacific. Lat. 55. 22. N. Long. 166. E. It is rocky, desolate, and uninhabited, and is only remarkable as being the place where the navigator Behring was wrecked, and died in 1741.

BEHRING'S STRAIT, the narrow sea between the N.E. part of Asia and the N.W. part of North America, connecting the North Pacific with the Arctic Ocean. At the narrowest part, East Cape in Asia approaches within about 36 miles of Cape Prince of Wales on the American shore. The former is in N. Lat. 66. 6. W. Long. 169. 38.; and the latter in N. Lat. 65. 46. W. Long. 168. 15. North and south of these points, the coasts on either side rapidly diverge. They are steep and rocky, and considerably indented. The Asiatic coast, extending from Cape Serdtzy to Cape Tchoukotzky, a distance of about 400 miles, presents several large and commodious bays. The strait is in general from 23 to 30 fathoms in depth, and contains a few small islands. Haze and fogs greatly prevail, and the temperature is low. This strait derives its name from Vitus Behring, a German in the Russian service, who sailed from Kamtschatka and discovered it in the year 1728. It was subsequently explored and described with great accuracy by Captain Cook, in 1788. An account of this strait, in connection with the discovery of the North-west Passage by Captain M'Clure, will be found under the head POLAR SEAS.

Beilan ‖ Bejapour.

BEILAN, a town and pass of Syria, on the east of Iskanderoon, nine miles from the coast of the Mediterranean. The pass, between mounts Rhosus and Amanus, is supposed to be the *Amanides Pylæ* of Strabo. The town is picturesquely situated near the top of the pass. Pop. about 5000.

BEINASCHI, GIOVANNI BATTISTA, an eminent historical painter, born in Piedmont in 1634. He studied at Rome under Pietro del Po; and some authors affirm that he was afterwards a disciple of Lanfranc. He was a good designer; and in acknowledgment of his merit, the honour of knighthood was conferred upon him. He died in 1688.

BEIT EL FAKIH (*i.e. house of the saint*), an unwalled town situated in Arabia Yemen, on a barren sandy plain, protected against the predatory incursions of the Arabs by a castle, in which the governor resides. It carries on an extensive trade in coffee, which grows on the hills 16 miles distant, and is carried to Mocha, the shipping port, and thence exported to Egypt, the East Indies, and to Europe. The trade of Beit el Fakih is carried on solely by the caravans; and the coffee is either sold for specie or for such goods as are required for the use of the inhabitants, who number about 8000. It is 24 miles E.S.E. of Loheia, and 60 leagues N. by E. from Mocha. Long. 43. 23. E. Lat. 14. 32. N.

BEITH, a town and parish of Scotland, in the county of Ayr, and partly also in Renfrewshire. The town is in Ayrshire, on the Renfrew and Ayr Railway, and nine miles S.W. of Paisley. It carries on to a considerable extent the manufacture of bleached and coloured thread, and has several cotton manufactories. Pop. of the town in 1851, 2016.

BEJA, a city of the province of Alentejo, in Portugal, 36 miles south of Evora. It is surrounded with walls, is the see of a bishop, and contains about 5500 inhabitants, who are for the most part occupied in cultivation, and especially in breeding cattle.

BEJAPOUR, in Southern India, the ancient capital of an independent sovereignty of the same name, and once an extensive, splendid, and opulent city, but now retaining only the vestiges of its former grandeur. It is situate in a fertile plain, and is a place of great extent, consisting of three distinct localities—the citadel, the fort, and the remains of the city. The citadel, a mile in circuit, is a place of great strength, well built, of the most massy materials, and encompassed by a ditch 100 yards wide, formerly well supplied with water, but now nearly filled up with rubbish, so that its original depth cannot be discovered. It was built in 1489, by Eusof Adil Shah, the founder of the dynasty of Bejapour. The fort consists of a rampart flanked by numerous towers, a ditch, and covered way. Its defences, which are not less than six miles in circumference, were completed by Ali Adil Shah in 1566. The interior formerly contained the king's palace, the houses of the nobility, large magazines, and extensive gardens. At present, though considerable portions of the area are covered with buildings or ruins, there is room for corn-fields and extensive inclosures. Outside the fort are the remains of a vast city, now for the most part in ruins, but the innumerable tombs, mosques, caravanseras, and other edifices which have resisted the havoc of time, afford abundant evidence of the ancient splendour of the place. It is asserted by the natives that Bejapour contained, according to authentic records, 1600 mosques and nearly 1,000,000 houses. The number of houses is certainly overrated; that of the mosques, in the opinion of recent travellers, is no exaggeration. The outer wall of the city on the western side runs nearly south

and north, and is of great extent. It is built of stone, is of prodigious thickness, and about twenty feet in height, with a ditch and rampart; and at intervals of 100 yards are capacious towers, built of large hewn stones. The whole is now in a ruinous condition; the wall and the towers having in many places fallen into the ditch, and in other parts being covered with rubbish. Several mosques and mausoleums, adorned with all the embellishments of Eastern architecture, are still to be seen in Bejapour. The fort in the interior is adorned with many of these edifices, in rather better preservation than the works. Amongst these is the great mosque, which is 97 yards long by 55 broad. The wings, which are 15 yards broad, project 73 yards from the north and south ends, inclosing on three sides, with the body of the mosque, a large reservoir of water and a fountain. The mausoleum of Sultan Mahmood Shah is a plain building, 153 feet square, over which is reared a dome 117 feet in diameter at its greatest concavity, and called by the natives the grand cupola. The mosque and mausoleum of Ibrahim Adil Shah, king of Bejapour—which was probably completed about the year 1620—is said to have cost L.700,000, and to have occupied thirty-six years in its completion. It is built on a basement 130 yards in length by 52 in breadth, and raised 15 feet. On it is a plain building, 115 feet by 76, covered by an immense dome raised on arches. The mausoleum is a room 57 feet square, inclosed by two verandahs 13 feet in breadth and 22 feet in height. There are, besides, many other public buildings more or less injured by time and the violence of the Mahrattas. Almost all the buildings, the palaces in the fort excepted, are of massive stone, and in the most durable style; and at the same time the workmanship is minutely elegant. Among the curiosities of the capital is the celebrated monster gun, stated to be the largest piece of cast brass ordnance in the world. It was captured from the king of Ahmednuggur by the king of Bejapour about the middle of the seventeenth century. An inscription on the gun recording the fact was erased by Aurungzebe, who substituted the present inscription, stating that he conquered Bejapour in 1685. The city is well watered, having, besides numerous wells, several rivulets running through it.

After the dissolution of the great Bahmani dynasty of the Deccan in 1489, a race of independent sovereigns arose, who ruled over the new kingdom of Bejapour, extending from the confluence of the Beema and the Krishna on the east to the sea-coast, on the west from Goa to Bombay. Their rule endured through several generations, until at length, in 1650, Shah Jehan compelled them to become tributary to the empire; and shortly after, their monarchy was totally subverted by his successor Aurungzebe. The city and territory of Bejapour remained annexed to Delhi till 1724, when the Nizam established his independence in the Deccan, and included Bejapour within his dominions. His sway over this portion of his acquisitions was, however, of brief duration, for, being defeated by the Peishwa in 1760, he was constrained to purchase peace by its cession to the Mahrattas. Upon the fall of the Peishwa in 1818, Bejapour passed into the hands of the British, and was by them included in the territory assigned to the rajah of Sattara.

The place, as already intimated, is rich in monuments of the bygone period when Bejapour was the capital of a powerful and flourishing Mahometan kingdom. Such traces of the past it is always desirable to preserve to the greatest possible extent, as they furnish the best commentary upon the history of the times in which they were raised, and indeed constitute their history, so far as manners are concerned. It is fortunate that their value was duly appreciated by the late rajah of Sattara, who took great pains to preserve them; and that the British government, participating in the same feeling, has, since the country passed into its possession, manifested great zeal in rescuing from the ravages of time the magnificent relics which have come into their possession.

Bejapour is distant from Sattara S.E. 130 miles; from Bombay S.E. 245. Lat 16. 50. Long 75. 48. (D. B–N.) (E. T.)

BEKES, a town of Hungary, capital of a county of the same name, situated at the confluence of the White and Black Koros, 14 miles N.N.W. of Gyula. The inhabitants, principally Calvinists, amount to about 17,000, and are chiefly engaged in agriculture and the rearing of cattle. Long. 20. 41. 37. E. Lat. 46. 46. 16. N.

BEKKER, Balthazar, a distinguished Dutch divine, born in Friesland in 1634, was the author of a work entitled *Die Betooverde Wereld*, or *The World Bewitched*, in which he exposed with irresistible force of reason the errors, absurdities, and impostures which had been propagated respecting spiritual agency; and which occasioned his deposition from the office of the ministry. He died in 1698. For an account of this remarkable man, who so far outstripped the age, see Apparitions. (Vol. III. p. 313.)

BEL, or Belius, *Matthias*, an Hungarian divine and historiographer to the Emperor Charles VI. His *History of Hungary* was so greatly admired that the emperor gave him letters of nobility; and notwithstanding his being a Lutheran, the pope, in 1736, sent him his picture and several gold medals. He was a member of the Royal Society of London, and of the academies of Berlin and Petersburg. He died in 1749, aged sixty-five.

Bel, or *Belus*, the supreme god of the ancient Chaldæans or Babylonians. He was the reputed founder of the Babylonian empire, and is supposed to be the Nimrod of Scripture, as well as identical with the Phœnician Baal. The term signifies Lord, and was applied by those nations to the sun. A temple was erected to Belus in the city of Babylon, on the uppermost range of the famous tower of Babel, in which there were many statues of the god, including one of massive gold forty feet in height. This temple, with its riches, was in existence till the time of Xerxes; but the Persian monarch, on his return from his unfortunate expedition into Greece, demolished it, and carried off the immense wealth which it contained. It was the statue of this god which Nebuchadnezzar set up and dedicated in the plain of Dura, on his return from the Jewish war.

Bel and the Dragon, an apocryphal book of Scripture. This book has always been rejected by the Jewish church: it is not extant either in the Hebrew or in the Chaldaic language, nor is there any proof that it ever was; hence St Jerome calls it the Fable of Bel and the Dragon.

BELAY, in *Seamanship*, to fasten by winding a rope round a kevel, cleat, or belaying-pin.

BELBEIS, or Belbeys, a town of Egypt, on the eastern arm of the Nile. It was formerly considered the bulwark of the kingdom on that side, and was defended by strong fortifications; but these were suffered to fall into decay till 1798, when Buonaparte ordered them to be put in repair. The present population is not supposed to exceed 5000. Belbeis is 28 miles N.N.E. of Cairo.

BELEMNITE (from *βέλεμνον*, a *dart*), vulgarly called *thunder-stone*, a marine fossil, common in the chalk and lime formations. The fossil shells of this genus are of a long conical shape, the interior cone being divided into partitions connected by a siphon (as in the Nautilus), and surrounded by numerous concentric layers composed of fibres radiating from the axis. This genus, of which there are many species, belongs to the order Cephalopoda. See Mollusca.

BELENYES, a town of Hungary, in the province of Farther Theiss, on the Körös, thirty miles S.S.E. of Grosswardein. It is the chief place of a small circle of the same name, and contains two Greek churches, one Roman Catholic, and one Calvinistic. Pop. 3250. Long. 22. 13. 25. E. Lat. 46. 40. 11. N

Belerium ‖ Belfast.

BELERIUM, in *Ancient Geography*, a promontory of the Dumnonii or Damnonii, the West Britons; now called the *Land's End.* (Diodorus Siculus, v. 21.)

BELESIS, a Chaldean priest at Babylon, who, according to Ctesias, conspired against Sardanapalus, and, in conjunction with Arbaces the Mede, overthrew the Assyrian empire, B.C. 876. He afterwards obtained from Arbaces the satrapy of Babylon. (Diodorus, ii.)

BELFAST, a maritime town, a municipal and parliamentary borough, the capital of Ulster, the chief manufacturing and commercial town in Ireland, and since 1850 the county town of Antrim. It is mainly comprised in the county of Antrim; but the large suburb of Ballymacarret, separated from the town by the river Lagan, is in the county of Down. Belfast is situated in Lat. 54. 36. 8·5. N., and Long. 5. 55. 53·7. W., at the mouth of the river Lagan, which flows immediately into Belfast Lough (Carrickfergus Bay), an estuary about 12 miles in length, and 5 miles broad. The town is built upon an alluvial deposit and land reclaimed from the sea, the greater portion being not more than six feet above high-water mark. In common with all places so situate, it is exposed to occasional inundations, and somewhat to the visitations of epidemics; but independently of the lowness of its site, Belfast is in other respects advantageously placed, and generally by no means unhealthful. The environs of the town are highly agreeable and picturesque.

The etymology of the name is uncertain, and its origin so obscure, that Belfast contains not one single memorial of past times deserving the notice of an antiquary. For a lengthened period the town consisted of a few houses, a church, and the castle, which latter edifice, used as a residence by the Chichester family, remained as a solitary relic of semi-barbarous times until the year 1708, when it was carelessly destroyed by fire, three daughters of the Earl of Donegal perishing in the flames.

The original charter constituting Belfast a corporation, consisting of a sovereign, twelve burgesses, and commonalty, with the privilege of sending two members to the Irish parliament, was granted in the tenth year of James I., although it was at that time a very inconsiderable place. This charter was renewed by James II. The municipal government of the borough was altered after the passing of the Act of Union, by the addition of police and life commissioners to the former corporation; and under this arrangement the borough was governed until the passing of the Municipal Reform Act in 1841, when the present corporation, consisting of a mayor, ten aldermen, and thirty town councillors, was instituted. At the Union, and until the passing of the Reform Act, Belfast returned one member to the imperial parliament; but that act granted two members to the borough, the constituency under the 13th and 14th Vict. cap. 69, numbering in 1853, 3282.

In the early part of the seventeenth century, and in connection with the project of James I. for the plantation of Ulster, many Scotch and English settled in the town and neighbourhood, and at that era commence the first signs of the future progress of Belfast. The great influence exerted by this infusion of new blood into the district is attested at the present time by the persistency of the lowland Scotch dialect and accent, the prevalence of the Presbyterian religion, and the physical characteristics of the people, no less than by their commercial activity, industry, and enterprise. For some time, however, the growth of the town was comparatively slow, and Milton, in his reply to the *Representation of the Presbytery of Belfast*, in 1649, describes it as a "small town in Ulster," and "a barbarous nook in Ireland." At the commencement of the eighteenth century, it had become known as a place of considerable trade, and what was then considered a handsome, thriving, and well-peopled town, with many new houses and good shops. Partly from good fortune, and more, perhaps, on account of the prudence of its inhabitants, Belfast suffered less during the civil commotions which so long afflicted the country than most towns in Ireland; its history is therefore fortunately barren of those exciting scenes so plentiful in the records of other important towns. Belford.

With regard to population, Belfast has been steadily progressive from an early period. In 1758 the number of inhabitants was 8549; in 1782, 13,105; in 1798, 18,320; in 1821, 45,177; in 1831, 48,224; in 1841, 75,308; and in 1851, 100,300. The custom duties collected at the port in 1784 amounted to L.104,376, and, after various fluctuations, reached L.288,756 in 1834, L.339,989 in 1843, and L.377,329 in 1852. The great increase of shipping frequenting the port appears in the following account of the number and tonnage of vessels entered inwards at various periods:—

Years.	No. of Vessels.	Tonnage.	Years.	No. of Vessels.	Tonnage.
1786	772	34,287	1825	2,060	183,441
1795	801	52,576	1835	2,730	290,769
1805	840	69,585	1845	3,655	445,537
1815	1,134	91,371	1851	5,016	650,938

The chief export trade is carried on by the cross-channel navigation; but a considerable direct trade also exists with the United States and Canada, the West Indies, the Mediterranean, and the Baltic.

Belfast is the centre of the Irish linen manufacture, to the cultivation of which it is mainly indebted for its prosperity. In 1841 about 240,000 spindles were employed, and the increase during the last ten years has been so rapid, that about 510,000 spindles are now in operation. The total value of all products of the linen manufacture exported abroad in the ten months ended 5th November 1852 was L.4,357,874, against L.4,150,157 in 1851; and the export of linens and yarns, especially of the latter, continues on the increase. In 1851, 5,060,160 lb. of linen yarns were exported from Belfast; and in 1852, 6,779,680 lb.

Externally, Belfast is pre-eminent among manufacturing towns for its cleanliness, elegance, and agreeable environs; the main streets are wide, and regularly built, chiefly of brick; and although inferior to Dublin in its public buildings, it possesses many of no mean architectural pretensions, and presents an appearance of bustling activity not to be found elsewhere in Ireland.

The river Lagan is crossed by three bridges of modern construction, the chief of which is the Queen's Bridge, erected on the site of the "Long Bridge of Belfast," and opened for traffic in 1844. There are 11 places of worship belonging to the Established Church, 21 Presbyterian, 8 Methodist, 3 Unitarian, and 4 Roman Catholic chapels, besides those belonging to other denominations. The chief educational establishments are the Belfast academy, the Royal Academical Institution, the new Queen's College, built of brick, in the Tudor style of architecture, and opened in 1849, the government school of design, &c.; and, proportionately to its extent, no town in the kingdom is better supplied with educational appliances than Belfast. The public buildings most worthy of notice are the white and brown linen halls, the corn exchange, the commercial buildings, the Museum, the Northern Joint-Stock and Belfast Banks, the theatre, the town-hall, the range of buildings containing the offices for the customs, inland revenue, and post-office departments, and the county lunatic asylum, about a mile distant from the town. The botanic garden, adjoining the Queen's College, is extensive, well kept, and beautiful.

The harbour of Belfast, originally a creek of the river Lagan, has been much improved of late years, and now allows vessels drawing eighteen feet of water to reach the quays at spring-tides. (H. S—R.)

BELFORD, a market-town of England, in the county of Northumberland, and northern division of Bamborough

Belfort || Belgium.

ward, 14 miles S.S.E. of Berwick. It is pleasantly situated on a gradual slope, about two miles from the sea, and on the Berwick and Newcastle railway. Pop. (1851) 1226.

BELFORT. See BEFORT.

BELFRY, BELFREDUS, is used by military writers of the middle ages to denote a tower erected by besiegers to overlook the place besieged. Sentinels were placed on the belfry to watch the avenues and prevent surprise, or to give notice of fires by ringing a bell. The word belfry is compounded of the Teutonic *bell*, and *freid*, "peace." Belfry also denotes that part of a steeple in which the bells are hung; sometimes called by old writers *campanile*, *clocaria*, and *tristegum*.

Belgica Gallia || Belgium.

BELGICA GALLIA, one of the three divisions of Gaul mentioned by Cæsar, and bounded by the ocean on the north, and east by the Rhine, on the west by the ocean, and on the south by the Seine and the Marne. The *Belgæ* are described by Cæsar as the bravest of the Gauls, because untainted by the importation of foreign luxuries. The collective forces of the whole nation exceeded a million.

BELGINUM, a town of the Treviri, in Gallia Belgica; now called *Baldenau*.

BELGIUM,

As a united state, did not exist in the middle ages. The country of which that kingdom has been formed was divided into a number of fiefs, independent of and frequently at war with each other. Amongst these fiefs may be mentioned the duchies of Brabant, Limbourg, and Luxembourg; the counties of Flanders, Hainault, and Namur; the bishopric of Liège; the lordship of Malines; and the principality of Stavelot. The Belgians took part in all the expeditions of those chivalrous times, and were seen fighting in the plains of the East. But in spite of the frequent wars in which they engaged, they enriched themselves by commerce and industry. Philip the Good, Duke of Burgundy, united them under his vast power, the bishopric of Liège and the principality of Stavelot alone maintaining a separate existence for more than four centuries. Under the Burgundian dominion, the Belgians became more and more prosperous; the brilliancy of their fêtes attracted numbers of cavaliers from all parts; whilst industry and commerce grew and prospered.

But the proper history of this country does not commence till the period when it came into possession of the house of Austria, by the marriage of the Archduke Maximilian, son of the Emperor Frederick III., in 1477, with Mary of Burgundy, only daughter and heiress of Charles the Bold.

Maximilian, when his son Philip had attained his twentieth year, resigned to him the government of the states; and at his death the inheritance of the Low Countries devolved upon the Archduke Charles of Austria, afterwards Charles V. The religious movement which then agitated Europe convulsed this country, which suffered fearfully under the cruel persecutions and oppression of Charles and his more bigoted son Philip II. The attempt to establish the inquisition at length roused the people to resistance, under the leadership of Count Brederode, a descendant of the ancient counts Holland. The insurgents presented to Margaret, Duchess of Parma, to whom Philip had intrusted the administration of Belgium, a demand for a redress of their grievances and the restoration of their rights. To this document they gave the name of the *compromise*, which was signed by above five hundred of the nobles and principal men in the state. On the rejection of this, they drove back the inquisitors to Spain, and religious liberty was proclaimed. This drew down upon them the wrath of Philip, who sent the Duke of Alva, at the head of the Spanish troops, to reduce them to subjection. He devastated the country, erected scaffolds in every city, and perpetrated the most cruel atrocities upon the inhabitants. At length the confederates formed an alliance with the Prince of Orange. For many years the conflict was carried on between the states of the Netherlands, under the house of Nassau, and the house of Austria, with varying success.

The death of Charles II. of Spain in 1700 gave rise to a general war, which extended to almost every part of the world. The dying king bequeathed his dominions to the Duke of Anjou, the grandson of Louis XIV., whose ambition had roused the jealousy of the other European states. This gave rise to the Grand Alliance. The Netherlands formed a part of the territory contended for, and again became the theatre of bloody battles and protracted sieges. The peace of Utrecht, concluded in April 1713, terminated the hostilities. By this treaty the ten provinces of Belgium, which now assumed the name of the Austrian Netherlands, were assigned to the emperor of Germany.

For a considerable time after this, in consequence of the weakness of the successors of Philip II., Belgium was in such a state of exhaustion, that Holland, to guard itself, occupied the greater part of her fortresses. The emperor had to treat with the states-general, and to accord to the Dutch advantages over the Belgians which excited the murmurs and threats of the inhabitants both against the emperor and the states-general; and it was only by extreme severity and the greatest precautions that a general revolt was prevented. But the prosperity which accompanied the subsequent peace reconciled the Belgian people to the Austrian rule.

The tranquillity of the Netherlands was interrupted by the war which broke out in 1743; but the treaty of Aix-la-Chapelle in 1748 re-established Maria Theresa in her Belgian possessions. Her good sense and good feelings preserved her from overstepping the bounds of the ancient laws; and her government, which was mild and prudent, remained popular with the people. She died in 1780, and was succeeded by her son Joseph II.

Joseph was inaugurated with the ancient formalities, and commenced his reign under favourable auspices. Anxious to promote the prosperity of the country, he resolved to deliver it from the yoke of Holland, to open up the navigation of the Scheldt, and, by the introduction of liberal commercial regulations, to restore it to its ancient importance. By various edicts he announced his determination to curb the power of the priests and to resist the papal encroachments; and even ordered the suppression of some of the monasteries. These reforms, too abruptly proposed, roused the opposition of the priesthood and the superstitious inhabitants, but they were not excited to revolt till Joseph began to overturn the civil departments by a complete change of system. The assembly of the states of Brabant then offered a determined opposition to his measures. They refused to vote the supplies, and in 1789 published a manifesto declaring Joseph II. deposed from the sovereignty. During the contests that followed, which were strongly marked by religious bigotry and fanaticism, Joseph died on the 20th January 1791, and was succeeded by his brother Leopold.

Leopold manifested much sagacity and moderation in his measures for the recovery of the revolted provinces. The states-general, on the other hand, occupied themselves almost exclusively in attempts to re-establish the monkish institutions; and having dismissed their able general Van der Mersch on account of his alleged heresy, their army became disorganized, and they had the temerity to reject with scorn the moderate overtures of the new emperor. The army of the imperialists advanced into the provinces; town after town

Belgium. opened its gates, and a short campaign gave the emperor quiet possession of the whole of the provinces. He revoked the ordonnances of his predecessor which had given such offence to the clergy and bigoted inhabitants, and re-established the form of government on the footing on which it had existed under Maria Theresa. These arrangements were scarcely completed when he died, on the 1st of March 1792. His son Francis II. succeeded to the throne, and under his reign the final separation of the Belgian provinces from the imperial family took place.

The new emperor, soon after his accession, found himself involved in the war with revolutionary France, which ended in the conquest of the Netherlands by the French. See FRANCE. The Netherlands were formed by the French first into the Batavian republic, afterwards into the kingdom of Holland for Louis Buonaparte; and in 1811, on his abdication, they were annexed to the French empire.

In 1813, after the battle of Leipzig and Napoleon's evacuation of Germany, the Dutch threw off the French yoke, and recalled the Prince of Orange, who assumed the reins of government under the title of king. The Belgian provinces were soon after abandoned by the French and fell by the right of conquest into the power of the allied sovereigns.

From its position Belgium had been the battlefield of Europe in former periods; and the possession of that country by France would be of vast importance as an advanced post, from which she might easily proceed to other conquests. The house of Austria, having always found the Belgian provinces a source of trouble and annoyance, was ready to abandon its claims; trusting thereby to secure some advantages nearer the centre of its power. The Netherlands, if united under one power, might be sufficiently strengthened to become a strong barrier against France, and the means of securing the continuance of that general peace which was then so much desired, and indeed wanted. Belgium, and the other territories near it, the bishopric of Liège, and the duchy of Luxembourg, were considered merely as European objects, which were so to be disposed of as would best suit the purposes of the combined powers, particularly that of securing the tranquillity of the great community of nations. It was not, then, from any peculiar favour to Holland, or from any personal regard to King William, though his minister formed one of the assembly, that, in less than two months after the seizure of Paris, it was adopted as a principle by the representatives of all Europe, and promulgated to the world, "that Holland, placed under the sovereignty of the house of Orange, should receive an increase of territory." This declaration was made on the 30th of May, and at the time received with general approbation, although at a subsequent period it was one of the principal grievances set forth by the Belgians in their declaration of independence. The principle thus announced received its final sanction by a treaty dated the 21st of July, in virtue of which Baron Vincent was to deliver over to King William the provisional power he exercised in Belgium, upon the following conditions, viz. 1. That the two countries should form one state, governed by the constitution already established in Holland, to be modified by common consent: 2. That there should be no alteration in that part which assured to all religious sects an equal admissibility to public offices: 3. That the states should assemble in alternate years in a city of Holland and in one of Belgium: 4. That all the inhabitants of both parts should be alike in all commercial matters, without any restriction being imposed on one for the benefit of the other: 5. That the provinces and cities of Belgium should be admitted to the full enjoyment of commerce with the colonies: 6. That all expenses should be in common, and the debts of the two parts should be assumed by the treasury of the kingdom: 7. That the expense of maintaining and strengthening the fortresses Belgium. should be defrayed from the common treasury: and, 8. That the cost of supporting the dikes should be furnished by the districts more immediately interested in them; but in case of any great disaster, succours were to be supplied by the general government, in the same manner as had formerly been practised in Holland. The king of England, by a separate treaty, on the 13th of August, agreed to give up to the newly-created king of the Netherlands all the conquests made from the Dutch during the war, with the exception of the Cape of Good Hope, and the settlements of Demerara, Essequibo, and Berbice, on the continent of South America.

By the treaty of the 21st of July, the government of the Netherlands accepted, on the conditions therein stated, that sovereignty over the Belgian provinces which the allied powers had offered, not from any peculiar feeling of regard to the interests of King William or of Holland, but as a European benefit, "de pourvoir à l'établissement d'un état d'équilibre en Europe, et en vertu de leur droit de conquête sur la Belgique." The duchy of Luxembourg was not a portion of Belgium, but a part of Germany; and that division was given up to the king of the Low Countries, by the German confederation, of which he was a member, not in his regal capacity, but in consequence of his transferring to Prussia the sovereignties, hereditary in his family, of Nassau-Dittenburg, Siegen, Hademar, and Dietz.

After the union of the two countries had been settled by treaty, and the whole delivered up to the government of William, it was thought necessary to submit, not the union itself, but the fundamental law or constitution, to the acceptance of the people. That constitution had already been accepted by an almost unanimous vote in the northern division, but it was deemed necessary to submit it also to the southern division. An assembly of Notables was accordingly convened in Belgium, on the same plan as had before been pursued in Holland. The number of the members of this assembly was 1600, but not more than 1325 attended. Upon the vote being taken, there appeared to be 529 in favour of accepting the constitution, and 796 against it; and thus, as far as that assembly was concerned, the acceptance of the proposed constitution was negatived. The government, however, took a different view of the subject, founded upon the assumption, that the union being adopted must be considered as a fact not to be questioned; and that this was a question for the united kingdom, which must be determined by a majority of the whole. For this purpose, the statistical view given of the kingdom was thus represented.

The inhabitants of the northern division, or what was before Holland, were	2,071,181
Those of the south part, or Belgium	3,411,082
In all	5,482,263
The votes in favour of the acceptance were stated to be the whole of the northern part	2,071,181
Two fifths of the southern part, who voted by their 529 delegates	1,364,432
	3,435,613
The majority of the Belgian representatives, who voted for three fifths of that part, amounted to	2,046,650
Thus giving in favour of the constitution, or fundamental law, a majority of	1,388,963

We have given an account of this proceeding, because it was subsequently made one of the grievances complained of. The assembly had been chosen fairly, and consequently under clerical influence, which was decidedly op-

Belgium. posed to the toleration of any other party than the Catholic religion. This was proved by a kind of protest, issued under the title of "Jugement Doctrinal des Evêques du Royaume des Pays-Bas, sur le serment préscrit par la Nouvelle Constitution." In an authoritative style it condemns the liberty given to appoint persons of any religious creed to offices of power and trust; and it reprobates the enactment that the Catholic church was to be submissive to the law of the state, that the other religious sects were to be protected in their worship, that the government was to have the power to regulate all the seminaries of the kingdom, and that the liberty of the press was recognised. It concluded with these words: "Mais dès qu'une loi humaine est intrinsèquement mauvaise, et opposée à la loi divine et aux lois de l'église, on ne peut, sous aucun prétexte, s'engager d'y obéir." This declaration was signed by all the prelates, viz. the Archbishop of Malines, and the Bishops of Ghent and of Tournay, and the vicar-general of the chapter of Liège. It is natural to suppose that such a declaration must have had great influence with people so ignorant and superstitious as the lower classes of the Belgian population are universally allowed to be, and averse as they had ever been to a connection with the Dutch, who were represented to them as a combination of heretics. The nobles are also said to have been more attached to the ancient Austrian government; but the middle classes were supposed to have more sympathy with the French than with the German nation, and to be peculiarly jealous of the Dutch.

Whatever may have been the common sentiment, of which it is always difficult to judge, not the least appearance of discontent was displayed at the promulgation of the constitution, or the public entry made by the king and his family into Brussels. His first efforts there, as they had been in Holland, were directed to the means of defence; and all due exertions were employed for the purpose of raising an effective and numerous army. In this much progress had been made when the intelligence arrived that Bonaparte had escaped from Elba, advanced in a sort of triumphal procession through France, and again assumed the imperial title, and all the power connected with it.

The alarm and terror created by this event had the effect of, in a great measure, disarming the power of the ecclesiastical fulminations, and uniting all classes with the new government in preparing for the contest which was evidently about to take place on the frontiers of the kingdom. The time spent by Bonaparte in Paris in organizing his recovered army, and in conciliating the several parties in his capital, was most actively employed by the king in strengthening his means of defence; and a great advance had been made in his military affairs, when it became evident that the first inroad of the French would be on the side of Belgium.

An army composed of Dutchmen and Belgians, but chiefly officered by the former, was collected and led towards the frontiers by the Prince of Orange. When the French entered Belgium, these troops formed the advance of the allied army. It encountered the French at Quatre-Bras, and, aided by the British, resisted during the whole day (the 16th of June) the attacks of the left division of the French army, commanded by Marshal Ney. The loss of lives on both sides was great; but that action had a powerful influence on the issue of the battle of the 18th, as it gave time to bring up the whole of the allied forces, and place them on the field of Waterloo, where the decisive conflict took place which decided the fate of the French empire, and gave a long peace to Europe. During the whole of that day the troops of the Netherlands sustained the character for courage which past centuries had established. There were probably a few instances of overpowering terror, and some solitary examples of disaffection, arising from past associations with the French; but the great principle of public duty pervaded the Netherlands army, as was proved by the loss which they sustained in the battle. The victory was cemented by the blood of the Prince of Orange, who stood at the head of his troops throughout the whole of that arduous day, encouraging them by his cool and determined conduct. On one occasion he made a desperate charge on the enemy, and advanced so far that he was actually in the midst of the French, and in the greatest danger, when a Belgian battalion rushed forward, repulsed the enemy, [illegible] a desperate struggle, disengaged the prince. From the [illegible] his gratitude, and his admiration of the bravery displayed, he tore from his breast one of the decorations gained by his conduct in some preceding action, and flung it amongst the battalion, calling out, "Take it, my lads; you have all earned it." This decoration was eagerly grappled for, and tied to the regimental standard amidst loud shouts of "Long live the Prince," and vows to defend the trophy, in the utterance of which many a brave man received the stroke of death. A short time afterwards, towards the close of the battle, the prince was hit by a musket-ball on the left shoulder. He was carried from the field, and conveyed to Brussels the same evening in a cart, accompanied by two of his aides-de-camp, one of whom, like himself, was badly wounded; displaying to those near him as much indifference to pain as he had previously shown contempt of danger. Belgium.

The battle of Waterloo appeared at the moment to have consolidated the establishment of the kingdom of the Netherlands. It seemed to have attached the military part of the Belgians to the prince who had been wounded at their head, and who had led them to that victory which they so mainly ascribed to their own exertions, as almost to forget that the troops of any other nation had contributed to it. Advantage was taken of this feeling to commence the working of the new constitution, which had been accepted, as before noticed, by a majority of the whole kingdom, though rejected by a majority of the Belgian portion. The solemn inauguration was held a few weeks after the battle, and much interest was excited by the appearance of the Prince of Orange, on the occasion, still wearing his wounded arm in a scarf, and with the pallid countenance of an invalid.

The constitution was then declared to have been accepted by the people, and no allusion was made to the irregularity of the decision, as the objections once urged had arisen from repugnance to religious toleration; those who had urged them being sensible that any allusions to the subject would have been unavailing amidst the prevailing military enthusiasm. None was made, but such were certainly nourished, to be brought forward at some moment more favourable for making the desired impression. No murmurs were heard, and Belgium became, or appeared to have become, reconciled to the arrangement which had been made by the allied powers.

The speedy concentration of the two divisions was a spectacle viewed with astonishment, whilst a thousand channels were opened for the egress of national industry, capital, and enterprise. Every obstacle seemed to have vanished, asperities were softened down or concealed, faction seemed dead or paralysed, and a quiet enjoyment of the present formed the only public manifestation. The people of Belgium appropriated to themselves the glorious victory of which their country had been the theatre. The king, by his love of peace, and by his activity in whatever could improve the institutions and the condition of the country, at first gained a high opinion amongst those Belgians who were able to endure the religious toleration he established; and amongst others his personal virtues, his

Belgium. domestic habits, and his unwearied industry, as favourable a view was taken of his character as could be formed of one who had the misfortune to be a heretic. This last party was soothed, if not reconciled, by the exertions which he made to recover and restore to their churches those pictures and other objects of value which had been pillaged by the French and carried to Paris.

The naval transaction of the following year, when a squadron of Netherlands ships joined the fleet under Lord Exmouth in the attack on Algiers, was another circumstance favourable to the consolidation of the new kingdom; for although the battle was gallantly fought by Dutchmen, yet the Belgians took care, in the exercise of their vanity, not to allude to the Hollanders; and as they had forgotten the English at Waterloo, so they now gladly assumed to themselves the glory of the united victory. The prosperity of Belgium made it the chosen residence of many respectable foreigners, as well as the place of refuge of others of the most opposite descriptions. The king busied himself less in projects to secure popularity, than in efforts to benefit the country; and it may here be proper to notice the institutions which were either established or ameliorated, and the beneficial consequences they produced.

Under the rule of France, Belgium, like the other parts of the Continent, had suffered severely from the operation of the conscription laws, which had deprived the country of those active labourers who were necessary to cultivate the fields. Although peace could not restore the great numbers who had perished, yet it stopped the farther progress of the evil in the Netherlands, by the establishment of a voluntary enrolment for a small regular army, and of a militia, whose service was required only for one month in the year. The mines felt the benefit of this regulation. The minerals of Belgium consist of coal, iron, and calamine. As soon as the union had been formed, and labourers became less scarce, a great impetus was communicated to this branch of industry; and companies were formed, who were most liberally repaid by the profit of their investments in this branch of industry, which was augmented from year to year as long as Belgium and Holland constituted one kingdom. By the excitement communicated to mining, the provinces of Liège and Hainault, and a part of Namur, were greatly enriched; and a company formed to explore the mines of Luxembourg were amply rewarded in their labours and their profits, till interrupted by internal commotions. The various branches of manufacturing industry received a similar impulse, though at first they were checked by the peace. The continental system of Bonaparte had given a factitious encouragement to some articles of manufacture, which ceased with the return of peace; and, till the formation of the kingdom of the Netherlands, many branches were depressed by the rivalry of foreign goods in the markets to which they had access. But as soon as the junction was completed, a stimulus was given to the manufacturers, by opening to their goods the markets of the East and West Indies, and those of all countries with which the Hollanders had traded. The iron manufactures of Liège advanced rapidly in prosperity; the woollen manufactures of Verviers felt most powerfully a similar impulsion; and many large establishments were formed at Ghent and other places, where cotton goods were fabricated which rivalled those of England, and so far surpassed those of France, that much of the goods were sold by the contraband trade in that kingdom. The opening of the Scheldt was the necessary effect of the formation of the united kingdom. Merchants from various countries formed establishments with large capitals at Antwerp; its docks became crowded with ships from all countries; its warehouses were loaded with colonial and other produce; and it advanced rapidly to a rivalry with Amsterdam, Rotterdam, and Hamburg, in the transit trade to the interior of Germany. The king directed his best efforts to the state of the roads, the greater part of which had suffered dilapidation, whilst the cross roads, so important in a country chiefly agricultural, were in many places scarcely passable. The management of the former was under the general government, whilst that of the latter was superintended by the local authorities; but in the first few years of the union the whole were repaired and placed in the most excellent state. The interests of internal navigation were sedulously watched over by the king. The old canals were repaired, the shallow parts of the rivers were deepened, and new and important water communications were formed. The chief of these, the Canal Guillaume, which extends from Maestricht to Bois-le-Duc, was an expensive but highly beneficial work; whilst that of Antoing in Hainault, that of Charleroy in the province of Namur, and that of Ternuse in Flanders, have been found in a very high degree beneficial. Though no longer of any importance to Belgium, it may not be quite out of place to remark, that the spirit of improvement which spread throughout the whole kingdom was to be seen in Holland in the Grand Canal of North Holland, which opens to Amsterdam a way for ships of the largest size to the ocean by way of the Helder, without incurring the risks arising from the shoals of the Zuyder Zee. Belgium.

Some other plans of this kind had been decided on, when the disturbances broke out which ended in this disjunction of Belgium from Holland. One of these was to make the river Sambre navigable; the other was to form a canal from the Meuse to the Moselle, by means of which the prosperity of the duchy of Luxembourg would have been greatly advanced.

The state of education, from the schools for primary instruction up to the universities, was in a wretched state when the king ascended the throne. In Holland it had ever been an object of the greatest consideration; and it had received from Louis Bonaparte, during his short reign, a degree of perfection which fitted it for reception in Belgium. Normal schools for the instruction of teachers were early founded; and as soon as any were found qualified, they were fixed with moderate stipends in the rural districts where they could be most beneficially placed. To such an extent was this plan of organizing primary schools carried during the first ten years of the reign of William, that their number in 1826 was 3329, in which the pupils were taught reading, writing, arithmetic, and the system of weights and measures. The numbers of pupils in the several schools of Belgium were 156,075 boys and 116,761 girls; in Luxembourg the numbers were 19,925 boys and 14,819 girls.

The schools for higher instruction were improved, and the number of students in them yearly increased. In ten years they had risen from 3400 to 7048. These were in general the institutions in which the youth were prepared for the universities. The king founded a new university at Liège, in addition to the two previously existing at Louvain and at Ghent. Great care was taken to procure the most able men in every branch of science; and as the country was rather deficient in such as possessed eminent qualifications, it was found necessary to repair to foreign lands for help. Several were invited from Germany, and others from France and Italy. No one establishment for education in Europe could boast of more distinguished names than those of the individuals who filled some of the professors' chairs, both in Liège and Ghent.

Whilst in the united kingdom the surface appeared smooth, and the vessel of the state seemed to be making a rapid progress, an under-current was perceived to be making its way in a direction not favourable to permanent tranquillity. At first William gained the highest applause from his Belgian subjects. The whole kingdom exhibited a show of bustling activity, if not of prosperity. Amongst the re-

Belgium.

fugees from other countries, the king and people were spoken of as models of public and domestic happiness; the diplomatists joined in the flattery, and prided themselves on the skill with which they had accomplished the tranquillity of Europe, by founding the kingdom of the Netherlands; and all united in the assertion that the king was much too good for his Belgian subjects.

For several years this favourable or flattering state of affairs continued, though thoughtful people soon discerned, from events unnoticed by superficial observers, the prognostics of future disunion. At the earliest meeting of the representative house, the different languages spoken by the members caused some difficulties; a Belgian in the discussions speaking in French, and a Hollander replying in Dutch. Too many of the questions brought forward might be of a local nature; and in these, as the whole of the Hollanders voted on one side, and the whole of the Belgians on the other, the decision was often dependent on the accidental absence of an individual on the one side or the other. The equality of numbers between the Dutch and Belgians made it difficult to come to a settlement on such subjects as affected the interests of the two countries in a different or opposite way. This was first exhibited on the subject of a free trade in corn. The Dutch provinces had never produced sufficient corn for their consumption, but a free trade in it had always furnished them with a sufficient supply. The Belgian provinces grew more corn than they consumed. As in the other parts of Europe during the last years of the war, the prices of corn had risen to an enormous rate, and the Belgian proprietors of land had increased their rents in due proportion. With the return of tranquillity the prices of grain and the rents of land were much reduced; and the Belgian members of the assembly desired to impose restrictions on the importation of grain. This was naturally opposed by the Dutch members, whose interest was engaged in favour of low prices, both as regarded the subsistence of the inhabitants, and the trade of the distilleries. The question was finally decided in favour of the freedom of the trade; but the contest gave rise to the formation of two parties, so equally balanced as to make the decision of many legislative questions dependent on accident.

As the royal authority had been established in Holland the greater part of a year before the union with Belgium, it had been organized without reference to that event. Holland had been a shorter period under French power; and during the prevalence of that influence when King Louis filled the throne, its government had been carried on upon the principle of nationality; the fittest men filled the offices in the different departments, and many of them remained unchanged when Holland became a French department. It was natural that King William should continue such men in their offices, and that in selecting officers for the new branches which were to be created, a preference should be given to natives, of whom there were numbers whose education, habits, and patriotism had well fitted them for the public service. At the union of Belgium and Holland the whole administration was in the hands of French functionaries, who speedily disappeared. Few men in Belgium had been brought up in such a way as to form them for official duties, and those who had sufficient information and capacity had been nominated to employments in the distant provinces of France. Under these circumstances, the greater number of officers was necessarily appointed from the northern division of the kingdom. Another cause of many offices in Belgium being filled by Dutchmen was, that some of those Belgians to whom offers were made declined to serve, on account of the influence of the priests, which prevented them from taking the oath to a constitution, one of the first stipulations of which was an equal freedom to all religions.

A complaint was brought forward, that in the appointment of officers in the army an undue preference had been shown in favour of the natives of Holland; and as Mr Northomb, an opponent of the house of Orange, in his work entitled *Essai Historique et Politique sur la Révolution Belge*, has placed the numbers in a statistical point of view, this matter is entitled to examination. According to his statement, in 1830 the officers of the army of the kingdom of the Netherlands is thus shown:

Belgium.

Rank.	Whole Number of Officers.	Belgians.	Belgians settled in Holland.
Generals	5	0	0
Lieutenant-generals.	21	2	1
Major-generals.	50	5	2
Colonels	48	8	1
Lieutenant-colonels.	48	9	1
Majors	137	19	0
Captains	211	38	3
Lieutenants	808	115	2
Sub-lieutenants	639	82	0
	1967	278	10

This great disproportion is in some measure lessened, from the circumstance that many of the officers were Germans, some were Swiss, and some were natives of other countries. With this allowance, the exact number of which is unascertained, the contrast between the whole and the Belgians is very striking. Baron de Keverburg, a partisan of King William, gives a different account, making the whole number of Belgians in the army to be 536 instead of 278. In his work entitled *Du Royaume des Pays Bas*, he asserts of his catalogue that it is " d'après des renseignemens puisés à des sources authentiques;" but, even on this showing, the more numerous population supplied but one fourth of the officers. This is accounted for, if not justified, by the baron, on various grounds.

When Louis Bonaparte became king of Holland, he sedulously attended to the formation of his army; and when he abandoned the throne the armed force was so well trained, equipped, and officered, that, on the annexation of Holland to France in 1810, it formed a military body equal to any other of the empire in its adaptation to the purposes of war. When that army was transferred to France, the different grades of officers retained their Dutch rank, and their former course of promotion. But when the people of Holland rose against France, and raised William to the throne, the Dutch resigned their posts in the French service, and repaired to their own country, where they were gladly received, and reinstated in the rank which they had attained during their service in France. It will be seen by the list of Mr Northomb that all the generals were Dutchmen; but that rank had been acquired in the French service, where, by their military talents, they had gained high reputation, and had been honoured and trusted by the French emperor. The names of the Dutch officers thus appointed generals by William are well known. Tindal had been raised by Bonaparte to the rank of general, and commanded a regiment of his body guard. Jansens had been distinguished as governor of Batavia, and in the army of the French emperor on the Ardennes frontier. Daendels was one of those Dutchmen who had been always placed in posts of the greatest danger, and had displayed the highest skill and valour. Dumonceau, though a Belgian by birth, had by his long service in the northern provinces become a Dutchman, and was highly esteemed in the French army. Chassé, an old officer of

Belgium. Holland when he was transferred to the French service, became known by the familiar title of *Général Baionnette*, and afterwards distinguished himself by his gallant defence of the citadel of Antwerp.

When men like these returned to their liberated country, and at a moment when their services were wanted, there were no rivals to compete with them in Holland, and they were necessarily placed at the head of their profession. Those of the successive ranks who also returned, as almost the whole did, were retained in those ranks in the army, formed first in Holland, and afterwards strengthened by the addition of Belgians. The Belgian officers serving in the French army had not been kept apart, but mixed up with the Frenchmen. They had formed a part of the general conscription; few had raised themselves to the rank of officers; and of these only three had attained the grade of colonel, no one having risen higher. Being thus insulated, they had nourished little or no national feeling; some few tardily returned to their native country after the occupation of Paris; but many of them remained in the service, and fought against their country at Waterloo.

The king, in the hasty organization of an army, naturally availed himself of the materials within his reach, and adapted them to the emergency. When after the battle of Waterloo peace was established, it would have been highly unjust to the brave men who had assisted there not to have confirmed them in their ranks, or to have placed others over them merely because they were born in Belgium. But for these, and even for such as had fought against their country, and repaired to it after the victory, the provision made was the best that could be effected at the time; and they were subsequently placed in new corps, retaining their former rank and seniority.

The utmost economy was practised respecting the army; and from the number of good officers in the highest classes, and their seniority, there was no prospect of rapid promotion. Thus the gentry of Belgium had but little inducement to enter the military service, so that, without attributing to the king any great partiality, the facts here stated sufficiently account for the greater number of officers belonging to one division of the kingdom.

The other charge of partiality on the part of the king, which ultimately became one of the grievances, was, that, in the legislative body, the number of deputies was as great from the northern as from the southern division of the kingdom, although the number of inhabitants in the latter was so much greater. The foundation of this settlement of the relative numbers was based upon the principle of giving legislative power according to the rate of revenue to be extracted from each division, rather than according to the number of the population. The proportion of revenue raised in Holland was nearly equal to that raised in Belgium; indeed it was shown, at a subsequent period, to be as fifteen to sixteen. The rate of revenue per head in Holland was sixteen florins, and in Belgium ten florins. Whether the rate of revenue or the number of inhabitants be the proper scale for regulating the proportion of legislators, is not a subject to be discussed in this place.

In the distribution of the higher civil offices of the government, complaints were urged and magnified into weighty grievances by the Belgians. On this subject the statements of Baron de Keverburg, when confirmed by the official part of *L'Almanach Royal*, are as follow:

The cabinet consisted of six members. It was formed before the union of the two countries, and was composed wholly of Hollanders; but after the junction of Belgium, two of the members withdrew, and two Belgians were admitted in their stead. The first chamber of the states-general, similar to our House of Peers, but nominated by the king for life, contained fifty-six members, of whom thirty were Belgians, and twenty-six Hollanders. The Belgium. *Conseil d'Etat*, or privy council, was composed of twelve Dutch and eleven Belgian members. The Prince of Orange and his brother Prince Frederick presided over the two divisions into which it was formed; one for the direction of the army, the other for that of the naval force. The *Chambre des Comptes*, or treasury, consisted of sixteen persons, taken equally from the two divisions of the kingdom. The judicial authority of the provinces and communes was in general intrusted to persons chosen in the division in which they were to execute their duties. There were a few exceptions to this rule, for two Dutchmen exercised these functions in Belgium; but two also, natives of Belgium, filled the same offices in Holland. Thus far there was an equality; but in North Brabant the judicial office was filled by a Belgian, which gave a trifling superiority to the southern division.

It may fairly be presumed, that in the appointment of officers in the several civil departments, the king had been mainly influenced by his view of the capacity of the persons selected to discharge the necessary duties; for at a subsequent period, when the most scrutinizing activity was exercised to discover grounds of complaint, no accusations were made of any other fault in the appointments than that which related to the portion of the kingdom to which the functionaries belonged. The king himself was active and regular; and being in a great degree his own prime minister, he must have been peculiarly anxious that the persons under him should be adapted to their several stations, and certainly under no government was more industry exercised or more regularity preserved.

Many of the important institutions of the country had, by the constitution, been left to the will of the king as to their local establishment. The seat of the states general had been fixed by that law to be alternately in Belgium and in Holland, but not the place for the king's residence or the council of state; yet these also, though with some personal and political inconvenience, were made changeable, business being transacted six months of each year at Brussels and six months at the Hague. But the supreme court of justice, the court of appeal from all the inferior tribunals of the kingdom, was permanently fixed at the Hague, to the great disadvantage of the more numerous suitors in the southern part of the kingdom. This formed a material, and apparently a just cause of complaint; and nothing has been stated by the Dutch which has disproved the inconvenience, though attempts have been made to represent the practical injury arising from it as very trifling and insignificant. Several other establishments were also made permanent in Holland, such as the state archives, the diplomatic offices, the council of the nobles, the coinage of money, the military and naval boards, the academies for the instruction of naval, artillery, and engineering officers, and the principal naval and military arsenals. This arrangement was justified upon public grounds by the partisans of the king. The kingdom, they affirmed, had been established as an European object, and to form a barrier for the defence of all the powers against the ambition of France. In any display of that ambition, Belgium would, as heretofore, become the first theatre of war, and, in spite of the range of fortresses about to be erected, might be occupied by an invading army. If the means of carrying on the war fell into the enemy's power, the effect might be fatal; but by having the establishments farther from the frontiers, and where they could be guarded by natural defences, the war might be kept up effectively behind the rivers and canals of Holland, so as to render the advance of the enemy a dangerous or a ruinous step.

There are in Belgium a variety of languages spoken, and the attempt of King William to introduce one uniform tongue created much discontent, and was by a great and

Belgium. influential part of the inhabitants considered as a serious grievance. The far greater portion of both the northern and southern inhabitants are of German origin, and their vernacular language is chiefly composed of Teutonic words. It is divided into several idioms, namely, the Dutch, the Flemish, and the Brabant. These three are so nearly similar, that those who use them understand each other better than the English and Scotch peasantry do. The Dutch language has been more polished than either of the others, having been the tongue of some of the most learned men that Europe has produced. It contains books of art, science, literature, law, theology, and history of the greatest merit, and which have been the means of spreading knowledge of all kinds to a great extent. The care bestowed on education has produced a greater number of readers and writers than are to be found in any other country of the same limited population. The Flemish and Brabant dialects have been little cultivated; few books have been written in it, except those of devotion, the lives of saints of the Catholic church, almanacs, and spelling-books. The numbers who read them are very small in comparison of the whole population, but with the rural inhabitants this dialect is the general medium of intercourse.

During the French dominion great pains were taken to extend the use of their language, and with much success as far as regarded those who had enjoyed the advantage of even the commonest education. This has extended the use of that language amongst those above the lowest classes; and it is said that even in Holland there are more persons acquainted with the French tongue than in those parts of Belgium where the other dialects of Teutonic origin are used. The Walloon language, a corrupted dialect of the French, is commonly used in the provinces of Hainault, Liège, and Namur; and the German language is most prevalent in Luxembourg.

Baron de Keverburg, assuming the population of 1829, gives the statistics of languages as follows.

The divisions in which the German is used, and their population:—

In Holland	2,329,974
In Belgium, the provinces of Antwerp, Limbourg, and the two Flanders	1,971,056
The largest part of Brabant	380,177
One half of Luxembourg	151,317
	4,832,524

The divisions in which the French and Walloon are used, with their population:—

The provinces of Hainault, Liège, and Namur	1,124,595
The arrondissement of Nivelles, in the province of South Brabant	126,733
One half of Luxembourg	151,317
	1,402,645

In this view the Dutch language is used by two fifths of the population, the other languages of German origin by two fifths, and the French and Walloon by one fifth. From the most remote periods all public affairs in Belgium were transacted in one or other of the Teutonic idioms. The *Joyeuse Entrée*, he Magna Charta of the country, was originally drawn up in the Teutonic dialect, and was only translated into French at a recent period, when the princes, no longer residing in the provinces, began to give a decided preference to that language; but all the proceedings of the states of Brabant were conducted in it till the conquest of the country by France. From that moment all public deeds were written in French, and the subdued people supported with pain the loss of their native tongue; but they dared not utter a complaint. This attachment of the Belgians to their native language was shown to have been little weakened by their subjugation to France; for when the allies had freed them from that yoke, and Baron Vincent was appointed governor *ad interim* by the house of Austria, a petition was presented to him by the ancient representatives of the city of Brussels, who resumed their former titles under the name of *Syndics des neuf nations, et des cent quarante-trois doyens*, complaining of the compulsory use of the French tongue. The petitions were favourably received, and an arrêt issued on the 18th of July, authorizing the use of the Flemish language, not, indeed, in all public writings, but in all notarial writings. Belgium.

When this provisional government ceased by the accession of King William to the throne of the Netherlands, he proposed to redress what was then deemed one of the grievances of the country, by a decree of the 1st October 1814, which stated as a fact. "that, in consequence of the union with France, the national languages of the provinces had been almost suppressed, to give place to the French tongue;" and then added, "that if it was necessary on one side still to tolerate the use of the latter language in some parts where the Flemish is not used, it is but just, on the other side, that the Flemish, which is the natural language of the country, should be re-established in all the parts in which it is used and understood." The king was certainly desirous of restoring the national language, and of restraining the use of the French; and for a time, whilst it was gratifying to the great body of the people, it occasioned very little complaint upon the part of those who alone spoke or understood French. Gradual enactments were made to induce practitioners to study the national languages; and three years were allowed to acquire them, at the end of which time those who did not understand them were to be removed to other stations, where they could practise their official duties in the tongue they were most familiar with. At the expiration of the prescribed time, 1st of January 1823, a decree fixed the following arrangement on the subject of languages:—1. The use of the French language shall be preserved in the Walloon provinces of Liège, Hainault, and Namur. 2. The use of the Dutch language shall continue to be maintained in Holland. 3. The use of the Flemish language, in its several idioms, shall be re-established in the Flemish provinces. 4. The German language shall be used in the German part of the grand duchy of Luxembourg. In short, it was provided that the official language in each of the provinces should be that which was used and understood by the mass of the people who inhabited them.

The profession of the law in Belgium forms a body which, next to the clergy, is the most formidable body of any. They had been trained by the study of French eloquence, and the young advocates, when called upon to plead in the language of the country, were often mortified by the ridicule of the audience. They did not wish to incur the displeasure of the Belgians by degrading their language, and therefore directed their attacks on the Dutch language, which, for that purpose, they confounded with the Flemish. In these attacks they were joined by the writers of many pamphlets, and also those of the public journals. The attacks were very violent. From those on the Dutch language they passed on to attacks on their literature, on their manners, and their morals. The Dutch writers, irritated by these attacks, replied and defended themselves; and thus arose, from mere literary disputes, a powerful and enduring animosity between the two countries.

The subject of religion was one which, above all others, served to produce discontent. A set of writers who neither had, nor pretended to have, any religious principles, encouraged the government at first in measures of toleration, according to the fundamental law, and were, or affected to be, vehement against the Jesuits, who opposed it. William was no bigot in religion, but it was his desire to raise the character of the Catholic clergy, by imparting

Belgium. to them a more extensive and better education than had previously been necessary before entering on their office. With this view he framed regulations which offended the clergy and the ignorant party who submitted to them, and who were at length joined by those who distinguished themselves as liberals, as soon as they saw that some advantages could be drawn from that union to forward their own republican views.

The Catholic clergy in Belgium had submitted to the regulation of their affairs which French subjugation had imposed. The vicar of the diocese of Ghent has indeed been unwilling to allow this; but Baron de Keverburg, himself a Catholic, and under the French regime governor of West Flanders, asserts most positively that the imperial institutions were observed in Belgium as elsewhere; that the catechism of the empire was taught to almost every one; and that the four articles of the clergy of France formed a part of the religious instruction in all the Belgian departments. As soon as the kingdom was established, they brought forward claims to power which they dared not even to whisper under Napoleon, and even carried those claims to an extent beyond what they had been urged for the last three or four centuries, and beyond what are acknowledged in the Catholic kingdoms of Europe.

The vicar-general of Ghent had required, as essential to the establishment of the kingdom of the Netherlands, " le rétablissement de tous les articles des anciens pactes inauguraux, constitutions, chartes, *et cetera*, en ce que concerne, non seulement le libre exercise de religion Catholique, mais aussi les droits, privilèges, exemptions, et prérogatives des évêques, prélats, des maisons-dieu, et des autres institutions religieuses quelconques." A single exception was indeed admitted to this exercise of power. The church would indulge the monarch so far as " accorder au prince et à sa cour des chapelles, bien entendu seulement dans l'enceinte des palais royaux." Thus these old powers, which the French had destroyed twenty years before, were to be restored; and then the prelates would allow, but only to the king and his family, the toleration of his own worship in secret. According to the principle of the prelates, the chief and sole duty of the temporal power was, in its relation to the Catholic church and its clergy, limited to " protéger la religion et ses ministres, à faire exécuter les lois de l'église, à faire punir les actes extérieurs nuisibles à la société religieuse."

This extraordinary claim of the church to a power independent of, and in fact governing the state, would not, on its own account, have deserved the notice here taken of it. It was at least quieted by the prudent conduct of the king, who suffered the Count Mean, one of the prelates, upon his nomination to a seat in the council of state, to swear to the tolerating constitution under a protest, that if the pope should declare the oath to be contrary to the rights of the church, it should thereby cease to be binding. The king, whilst he adhered to the constitutional principle of tolerating other sects, extended his liberality to the Catholic clergy, by increasing the stipends of the inferior orders; by making provision for those who, from age or infirmity, were incapable of performing their duty; and by contributing liberally to the erection or repairs of churches where the communal funds were inadequate to the purpose. The opposition of the clergy was for a time dormant; but it was again roused, when, at a subsequent period, the leaders of the church formed a junction with the leaders of the French party, and thus placed the lower classes, who could not read their effusions, but were under the influence of the priests who spoke to them in Flemish, in a state of hostile excitement towards the government. The hostility of the clergy was much aggravated by the attempts made to improve the education of the priests. The king had determined that no priest should be inducted who had not passed two years in the study of the *literæ humaniores* before his ordination, and appropriated a college at Louvain for that purpose, to which was given the unfortunate name of the *philosophical* college, a name with good Catholics almost equivalent to infidel or heretic. The prelates, to counteract this, established seminaries connected with the cathedrals, in which the pupils were instructed in their humanities. These contravened the design of the king, and were forcibly shut up. It was an objection to the philosophical college that the professors of history were not priests, but laymen, and some Protestants. This may not seem a solid ground of declining to attend lectures on history; but it was so with the Catholics; for, as their doctrines rest quite as much on tradition as on the Holy Scriptures, it was of vast importance that history should be taught by those alone who were orthodox in their opinions. In truth, the critical spirit of some of the German professors would make sad work with many parts of the traditions held sacred by the Catholic church. The prelates, in the discussions on this subject, indulged in language of a violent kind, and were prosecuted. A law enacted by Napoleon was made the instrument of condemning one or two of them to banishment, and excited no small degree of hatred amongst their adherents, who, if not the most enlightened, were the most numerous, portion of the inhabitants. These mortifications were increased by circumstances of inferior importance. Some of the religious festivals were curtailed, certainly with no views inimical to religion, but to benefit the morals of the people, by lessening the number of days that were devoted to idleness and drunkenness. The architecture of the national schools was similar to that of the reformed places of worship, and the youth of the country were forbidden to be educated out of the kingdom. These trifles were magnified into matters of plain evidence of a regular system to proselytise the whole of the Netherlands. Whilst these controversies respecting religion and education were carried on, the conduct of the king was applauded and encouraged by the active party of the liberals, who represented them as proper steps to secure the people from the insidious attempts made by the Jesuits to blind and cajole them. There was no evidence of any plan of the kind on the part of the Jesuits, and it was only affectation in the liberals to insinuate it. It served their turn for the time, but was soon forgotten, when it appeared advantageous for their party purposes to join with the most bigoted of the Catholics against the government of the house of Orange.

Another subject was at times brought forward, and must be added to the causes of the internal disunion between the two parts of the kingdom. The number of members of the representative body had been fixed at the time of the union, and made equal for Holland and for Belgium. The subject was then investigated with the greatest deliberation, and all parties were content. It had been suggested that Belgium brought, to form the kingdom, a more numerous population than Holland, and therefore ought to have a greater proportion of members in the assembly. But, upon the other hand, it was shown that the colonies which Holland brought to the common stock contained, in Asia, Africa, and America, as many persons as rendered them equal in number, and, in regard to common advantage, much superior to Belgium; and, besides this, it was urged, that the Dutch contributed to the common cause a powerful fleet and an army, with the stores belonging to both services. This point was, however, settled with perfect cordiality, and remained at rest during several years. But at length it was thought necessary to extend to Belgium the Dutch system of taxation on the grinding of corn. This was severely felt, and gave rise to renewed agitation as to the inequality of representation in reference to the numbers of inhabitants. It became a more prominent

Belgium. object, because the tax was imposed only by a majority of two votes, all the Hollanders voting for the measure, and all the Belgians but two against it.

During the whole of the period from 1815 to 1829 the popularity of the monarch was very variable. After the uttering of some loud complaints, as alleged grievances arose, they seemed to die away and be forgotten; and, till some new cause supervened, the king was as much respected as his best friends could wish. At no time, indeed, was his personal character assailed; and the general feeling in Belgium was, that he always meant well, but gave too ready an acquiescence to what they tauntingly called the schemes of their *Dutch cousins*.

The king, attacked by two parties, by the priests and their bigoted followers on one side, and by the republicans on the other, avowed his intention to act with indifference to all parties in the pursuit of what he deemed for the general advantage. In conformity with this disposition a *concordat* was in 1827 entered into with the pope, by which the right of nomination to the bishoprics was settled. It was provided that each should be selected by the pope out of three individuals to be nominated by the king, and that the education of the priests should be under the control of the prelates; but that in the seminaries professors should be appointed to teach the sciences, as well as what related to ecclesiastical matters. This arrangement was highly satisfactory to the cool and thinking part of the community, but was far from pleasing to the extravagant partisans. The clergy thought that too little had been granted to them, and the liberals that too much power was conferred on their order. Conciliatory as this measure was intended to be, it thus proved nugatory; and several nominations of Belgians to offices before filled by Dutchmen had no better effect.

Brussels at this time contained a most heterogeneous foreign population, consisting of the intriguing and discontented subjects of almost every country of Europe. There were of Frenchmen, regicide conventionalists, exiled Napoleonists, and proscribed constitutionalists, besides Italian carbonari, expatriated Poles, Spanish liberals, disgraced Russians, English and Irish radicals, and visionary students from the various parts of Germany. As the greater part of these had but insecure means of subsistence, and for the most part understood the French language, the press groaned with libels, not more against the Belgian than against all other governments, and thus contributed towards the production of a high state of political excitement. The press of the capital also furnished cheap editions of such works as, either from their irreligious, immoral, or democratic tendency, were prohibited in France; and thus became a nuisance to the regular governments of Europe. The great mass of the population could not be inflamed by these fire-brands; few of them could read, and fewer still could read French. They were, however, acted upon by other means. The Flemish preachers, schoolmasters, and confessors, in their several spheres, were ready to join in any movement, and were sure to be supported by the idle, the dissolute, and the indigent, with which the cities and large towns abounded. To bring the whole body of discontent to bear upon the same point, it was found advisable to form the two parties into one; and this was achieved by the liberals affecting a zeal for the Catholic faith, which they had before treated with contempt and ribaldry. The union was thus formed, meetings of the parties were held, the junction was openly announced, and threatenings were promulgated tending to give confidence to the confederacy, as well as to excite apprehension in the king and his ministers.

This system of agitation was carried to an extent which no government could behold with indifference, however confident in the rectitude of its measures. It was attempted to oppose the calumniating writers by employing others to counteract their influence; but the attempt was far from successful, as in that kind of warfare the assailants have almost always the advantage on their side. The avowed object of the liberal writers was to urge the clerical party to make such extravagant demands of extensive power as they knew, if granted, would be the ruin of the royal authority, and if refused, would increase the agitation they had already created. Although the whole of the Dutch members of the representative assembly, and several of the most respectable of the Belgian members, gave a majority in favour of the royal party, yet many of the latter adopted most inflammatory language, and, as far as the rules of debate allowed, seconded the views of the united party of the liberals and bigots. Belgium.

As the union openly flung defiance at the government, it appeared necessary to bring before the courts of law the most notorious of the inflammatory writers; and two were selected as subjects for prosecution before the court of assizes of South Brabant. These individuals are thus described by the Baron de Keverburg. Of the first, Louis de Potter, he says, " Il s'était fait remarquer longtemps avant les troubles de la Belgique par dés écrits qui, aux yeux de l'église, étaient reputés fort impies, et, aux yeux des hommes doués, d'un peu de délicatesse, de très-mauvais gout. Ce que j'ai de dire sur le second est moins honorable encore. M. François Tielemans, avant l'époque pre-indiqué, n'était connu que par les bienfaits qu'il avait reçus et qu'il continuait de recevoir du roi, et plus tard il le fut par son ingratitude envers son bienfaiteur."

These men, with two others, likewise editors of journals, were sent to the tribunal in which Van Maanen filled the office of presiding judge. The prosecution terminated in a sentence of banishment from the kingdom for the period of eight years; a sentence which brought on the judge the execrations of the libellous journals, and elevated the prisoners to the rank of martyrs. The sentence was put in force by sending the culprits to the frontiers, where they were detained, as neither of the neighbouring states would admit them. The revolution of July occurred in Paris whilst they were in this state; and the party which prevailed in that city allowed them to enter France, and they were received in the capital with great applause by the propagandists.

The popular mind in Brussels was highly agitated by these trials, which did not operate to restrain the indignant language of the journals, nor the distribution of the most vehement placards, many of them in the Flemish tongue, in which the minister Van Maanen, and the editor of a royalist journal entitled the *National*, were held up to the public indignation, and threatened with vengeance. In this state of the public feeling, the news of the success of the Parisian mob in overturning the throne was received with enthusiasm. Numbers of the young propagandists from Paris reached Brussels. Assuming to themselves the character of heroes of the revolution, and with feelings of disappointment at the tranquil issue at which it had so soon arrived, these young men displayed the three-coloured cockade in the streets and public places; talked loudly in the theatres and coffee-houses; sang the Marseillaise and Parisienne hymns in chorus with impassioned groups; and dwelt with enthusiasm on the glories of the republic and the empire, and the future destinies of their " young France." Some of the more active of the Belgians repaired to Paris, and are said to have sounded the new government on the subject of the re-union of their country to France, in the event of the dissolution of the monarchy of the Netherlands. These last were, however, mere adventurers, who had little or no power over, or intercourse with, those who were destined to influence the fate of Belgium.

Belgium. to them a more extensive and better education than had previously been necessary before entering on their office. With this view he framed regulations which offended the clergy and the ignorant party who submitted to them, and who were at length joined by those who distinguished themselves as liberals, as soon as they saw that some advantages could be drawn from that union to forward their own republican views.

The Catholic clergy in Belgium had submitted to the regulation of their affairs which French subjugation had imposed. The vicar of the diocese of Ghent has indeed been unwilling to allow this; but Baron de Keverburg, himself a Catholic, and under the French regime governor of West Flanders, asserts most positively that the imperial institutions were observed in Belgium as elsewhere; that the catechism of the empire was taught to almost every one; and that the four articles of the clergy of France formed a part of the religious instruction in all the Belgian departments. As soon as the kingdom was established, they brought forward claims to power which they dared not even to whisper under Napoleon, and even carried those claims to an extent beyond what they had been urged for the last three or four centuries, and beyond what are acknowledged in the Catholic kingdoms of Europe.

The vicar-general of Ghent had required, as essential to the establishment of the kingdom of the Netherlands, "le rétablissement de tous les articles des anciens pactes inauguraux, constitutions, chartes, *et cetera*, en ce que concerne, non seulement le libre exercise de religion Catholique, mais aussi les droits, privilèges, exemptions, et prérogatives des évêques, prélats, des maisons-dieu, et des autres institutions religieuses quelconques." A single exception was indeed admitted to this exercise of power. The church would indulge the monarch so far as "accorder au prince et à sa cour des chapelles, bien entendu seulement dans l'enceinte des palais royaux." Thus these old powers, which the French had destroyed twenty years before, were to be restored; and then the prelates would allow, but only to the king and his family, the toleration of his own worship in secret. According to the principle of the prelates, the chief and sole duty of the temporal power was, in its relation to the Catholic church and its clergy, limited to "protéger la religion et ses ministres, à faire exécuter les lois de l'église, à faire punir les actes extérieurs nuisibles à la société religieuse."

This extraordinary claim of the church to a power independent of, and in fact governing the state, would not, on its own account, have deserved the notice here taken of it. It was at least quieted by the prudent conduct of the king, who suffered the Count Mean, one of the prelates, upon his nomination to a seat in the council of state, to swear to the tolerating constitution under a protest, that if the pope should declare the oath to be contrary to the rights of the church, it should thereby cease to be binding. The king, whilst he adhered to the constitutional principle of tolerating other sects, extended his liberality to the Catholic clergy, by increasing the stipends of the inferior orders; by making provision for those who, from age or infirmity, were incapable of performing their duty; and by contributing liberally to the erection or repairs of churches where the communal funds were inadequate to the purpose. The opposition of the clergy was for a time dormant; but it was again roused, when, at a subsequent period, the leaders of the church formed a junction with the leaders of the French party, and thus placed the lower classes, who could not read their effusions, but were under the influence of the priests who spoke to them in Flemish, in a state of hostile excitement towards the government. The hostility of the clergy was much aggravated by the attempts made to improve the education of the priests. The king had determined that no priest should be inducted who had not passed two years in the study of the *literæ humaniores* before his ordination, and appropriated a college at Louvain for that purpose, to which was given the unfortunate name of the *philosophical* college, a name with good Catholics almost equivalent to infidel or heretic. The prelates, to counteract this, established seminaries connected with the cathedrals, in which the pupils were instructed in their humanities. These contravened the design of the king, and were forcibly shut up. It was an objection to the philosophical college that the professors of history were not priests, but laymen, and some Protestants. This may not seem a solid ground of declining to attend lectures on history; but it was so with the Catholics; for, as their doctrines rest quite as much on tradition as on the Holy Scriptures, it was of vast importance that history should be taught by those alone who were orthodox in their opinions. In truth, the critical spirit of some of the German professors would make sad work with many parts of the traditions held sacred by the Catholic church. The prelates, in the discussions on this subject, indulged in language of a violent kind, and were prosecuted. A law enacted by Napoleon was made the instrument of condemning one or two of them to banishment, and excited no small degree of hatred amongst their adherents, who, if not the most enlightened, were the most numerous, portion of the inhabitants. These mortifications were increased by circumstances of inferior importance. Some of the religious festivals were curtailed, certainly with no views inimical to religion, but to benefit the morals of the people, by lessening the number of days that were devoted to idleness and drunkenness. The architecture of the national schools was similar to that of the reformed places of worship, and the youth of the country were forbidden to be educated out of the kingdom. These trifles were magnified into matters of plain evidence of a regular system to proselytise the whole of the Netherlands. Whilst these controversies respecting religion and education were carried on, the conduct of the king was applauded and encouraged by the active party of the liberals, who represented them as proper steps to secure the people from the insidious attempts made by the Jesuits to blind and cajole them. There was no evidence of any plan of the kind on the part of the Jesuits, and it was only affectation in the liberals to insinuate it. It served their turn for the time, but was soon forgotten, when it appeared advantageous for their party purposes to join with the most bigoted of the Catholics against the government of the house of Orange.

Another subject was at times brought forward, and must be added to the causes of the internal disunion between the two parts of the kingdom. The number of members of the representative body had been fixed at the time of the union, and made equal for Holland and for Belgium. The subject was then investigated with the greatest deliberation, and all parties were content. It had been suggested that Belgium brought, to form the kingdom, a more numerous population than Holland, and therefore ought to have a greater proportion of members in the assembly. But, upon the other hand, it was shown that the colonies which Holland brought to the common stock contained, in Asia, Africa, and America, as many persons as rendered them equal in number, and, in regard to common advantage, much superior to Belgium; and, besides this, it was urged, that the Dutch contributed to the common cause a powerful fleet and an army, with the stores belonging to both services. This point was, however, settled with perfect cordiality, and remained at rest during several years. But at length it was thought necessary to extend to Belgium the Dutch system of taxation on the grinding of corn. This was severely felt, and gave rise to renewed agitation as to the inequality of representation in reference to the numbers of inhabitants. It became a more prominent

Belgium. object, because the tax was imposed only by a majority of two votes, all the Hollanders voting for the measure, and all the Belgians but two against it.

During the whole of the period from 1815 to 1829 the popularity of the monarch was very variable. After the uttering of some loud complaints, as alleged grievances arose, they seemed to die away and be forgotten; and, till some new cause supervened, the king was as much respected as his best friends could wish. At no time, indeed, was his personal character assailed; and the general feeling in Belgium was, that he always meant well, but gave too ready an acquiescence to what they tauntingly called the schemes of their *Dutch cousins*.

The king, attacked by two parties, by the priests and their bigoted followers on one side, and by the republicans on the other, avowed his intention to act with indifference to all parties in the pursuit of what he deemed for the general advantage. In conformity with this disposition a *concordat* was in 1827 entered into with the pope, by which the right of nomination to the bishoprics was settled. It was provided that each should be selected by the pope out of three individuals to be nominated by the king, and that the education of the priests should be under the control of the prelates; but that in the seminaries professors should be appointed to teach the sciences, as well as what related to ecclesiastical matters. This arrangement was highly satisfactory to the cool and thinking part of the community, but was far from pleasing to the extravagant partisans. The clergy thought that too little had been granted to them, and the liberals that too much power was conferred on their order. Conciliatory as this measure was intended to be, it thus proved nugatory; and several nominations of Belgians to offices before filled by Dutchmen had no better effect.

Brussels at this time contained a most heterogeneous foreign population, consisting of the intriguing and discontented subjects of almost every country of Europe. There were of Frenchmen, regicide conventionalists, exiled Napoleonists, and proscribed constitutionalists, besides Italian carbonari, expatriated Poles, Spanish liberals, disgraced Russians, English and Irish radicals, and visionary students from the various parts of Germany. As the greater part of these had but insecure means of subsistence, and for the most part understood the French language, the press groaned with libels, not more against the Belgian than against all other governments, and thus contributed towards the production of a high state of political excitement. The press of the capital also furnished cheap editions of such works as, either from their irreligious, immoral, or democratic tendency, were prohibited in France; and thus became a nuisance to the regular governments of Europe. The great mass of the population could not be inflamed by these fire-brands; few of them could read, and fewer still could read French. They were, however, acted upon by other means. The Flemish preachers, schoolmasters, and confessors, in their several spheres, were ready to join in any movement, and were sure to be supported by the idle, the dissolute, and the indigent, with which the cities and large towns abounded. To bring the whole body of discontent to bear upon the same point, it was found advisable to form the two parties into one; and this was achieved by the liberals affecting a zeal for the Catholic faith, which they had before treated with contempt and ribaldry. The union was thus formed, meetings of the parties were held, the junction was openly announced, and threatenings were promulgated tending to give confidence to the confederacy, as well as to excite apprehension in the king and his ministers.

This system of agitation was carried to an extent which no government could behold with indifference, however confident in the rectitude of its measures. It was attempted to oppose the calumniating writers by employing others to counteract their influence; but the attempt was far from successful, as in that kind of warfare the assailants have almost always the advantage on their side. The avowed object of the liberal writers was to urge the clerical party to make such extravagant demands of extensive power as they knew, if granted, would be the ruin of the royal authority, and if refused, would increase the agitation they had already created. Although the whole of the Dutch members of the representative assembly, and several of the most respectable of the Belgian members, gave a majority in favour of the royal party, yet many of the latter adopted most inflammatory language, and, as far as the rules of debate allowed, seconded the views of the united party of the liberals and bigots. Belgium.

As the union openly flung defiance at the government, it appeared necessary to bring before the courts of law the most notorious of the inflammatory writers; and two were selected as subjects for prosecution before the court of assizes of South Brabant. These individuals are thus described by the Baron de Keverburg. Of the first, Louis de Potter, he says, " Il s'était fait remarquer longtemps avant les troubles de la Belgique par dés écrits qui, aux yeux de l'église, étaient reputés fort impies, et, aux yeux des hommes doués, d'un peu de délicatesse, de très-mauvais gout. Ce que j'ai de dire sur le second est moins honorable encore. M. François Tielemans, avant l'époque pre-indiqué, n'était connu que par les bienfaits qu'il avait reçus et qu'il continuait de recevoir du roi, et plus tard il le fut par son ingratitude envers son bienfaiteur."

These men, with two others, likewise editors of journals, were sent to the tribunal in which Van Maanen filled the office of presiding judge. The prosecution terminated in a sentence of banishment from the kingdom for the period of eight years; a sentence which brought on the judge the execrations of the libellous journals, and elevated the prisoners to the rank of martyrs. The sentence was put in force by sending the culprits to the frontiers, where they were detained, as neither of the neighbouring states would admit them. The revolution of July occurred in Paris whilst they were in this state; and the party which prevailed in that city allowed them to enter France, and they were received in the capital with great applause by the propagandists.

The popular mind in Brussels was highly agitated by these trials, which did not operate to restrain the indignant language of the journals, nor the distribution of the most vehement placards, many of them in the Flemish tongue, in which the minister Van Maanen, and the editor of a royalist journal entitled the *National*, were held up to the public indignation, and threatened with vengeance. In this state of the public feeling, the news of the success of the Parisian mob in overturning the throne was received with enthusiasm. Numbers of the young propagandists from Paris reached Brussels. Assuming to themselves the character of heroes of the revolution, and with feelings of disappointment at the tranquil issue at which it had so soon arrived, these young men displayed the three-coloured cockade in the streets and public places; talked loudly in the theatres and coffee-houses; sang the Marseillaise and Parisienne hymns in chorus with impassioned groups; and dwelt with enthusiasm on the glories of the republic and the empire, and the future destinies of their " young France." Some of the more active of the Belgians repaired to Paris, and are said to have sounded the new government on the subject of the re-union of their country to France, in the event of the dissolution of the monarchy of the Netherlands. These last were, however, mere adventurers, who had little or no power over, or intercourse with, those who were destined to influence the fate of Belgium.

Belgium. The disturbances which followed at first may be easily concluded to have been the result of mere popular excitation, such as is often seen in large cities. The first symptom of outrage was presented by the audience of the theatre, on the 25th of August 1830, after the representation of a piece, the *Muette de Portici*, which abounded with passages well calculated to kindle a flame amongst materials well charged with inflammable particles. When the curtain fell, the excited audience rushed into the street, exclaiming, "To the office of the National." They ran thither, soon forced in the doors and windows, and began the work of destruction. They then rushed into the dwelling of the editor, which was speedily demolished, though the obnoxious individual, whose life was threatened, made his escape unhurt. The house of Van Maanen was that next assailed. It was plundered, and then set on fire, and the populace stopped the fire-engine from playing till every thing in it was consumed. The police-office was then attacked; the books, furniture, pictures, and plate of the chief magistrate were brought out and burnt in the street; and the hotel of the provincial governor shared the same fate; whilst some private houses and several manufactories were pillaged, and otherwise much damaged. Fury, confusion, or terror were visible in every countenance, before the civil and military powers made any attempts to stop these disorders; and those which were made showed a want either of the courage or the coolness necessary to act with decision. "From this conduct," says an eye-witness, "before ten o'clock on the morning of the 26th, the guards and posts in the centre of the city had been overcome, or had tranquilly surrendered; and the troops who had been drawn out either retreated to their barracks, or were withdrawn to the upper part of the city, where they piled their arms in front of the king's palace, and renounced all attempts at suppressing the tumult."

By the operations of these two days, the multitude had in fact gained the mastery of the city, and every one in it felt himself exposed to whatever private malice, political fury, or the love of plunder, might induce the populace to inflict. This moved a few of the more influential inhabitants to take up arms, and to enrol themselves into a burgher guard, for the protection of their lives and property. Within three days, not less than as many thousand persons, chiefly heads of families, had enrolled themselves in this corps, and, under chiefs of their own selection, paraded the streets; so that, if they did not put a stop to plunder and destruction, they at least contributed in some degree to contract the extent of the mischief. In such circumstances, the actual power within the city devolved on those who obtained the direction of these hastily organized and scarcely armed citizens. They determined on resisting the troops, which were advancing; and the general who commanded them having no precise orders from the king to act, readily agreed to suspend the march, and entered into a kind of treaty of neutrality with the burghers, till they could receive directions from the Hague, where the king and his family had that year their residence. The intelligence of these events in the capital soon spread throughout the provinces, and in all the large towns, excepting Antwerp and Ghent, similar scenes were exhibited, commencing with plunder and outrages by mobs, and settling down into an uneasy but rather more secure state by the institution of burgher guards.

The intelligence from Brussels was quickly communicated to the Hague, but the royal councils were divided in opinion. The only positive demand in Brussels was the dismission of the minister Van Maanen; and he offered to resign his post. The king is said to have refused accepting his resignation, whilst the Prince of Orange urged the acceptance of it, and the adoption of some other measures of a conciliatory kind. The result of the decision can only be known by the events which followed: and they show Belgium. that neither the adoption of concessions, nor the positive use of force, was resolved upon, but a course was pursued which, being some undefined medium between the two different paths, ended, as was natural, in converting a mere popular riot into a confirmed revolution. It was determined by the council that the Prince of Orange should proceed to Brussels on a peaceful commission; whilst the command of the army was conferred on his brother, and the troops advanced with alacrity from the various parts of Holland, where they were quartered, and where the most astonishing zeal was displayed in support of the royal authority.

The prince, however, departed for Brussels, but only furnished with such limited powers as, in the actual circumstances, were utterly ineffective. On his arrival at Vilvorde, near the city, he was waited on by a deputation from the city, composed of some of the most respectable inhabitants, who had been nominated at a public meeting of the householders. After some preliminary discussions, the prince courageously resolved on entering the city with no other suite than a few officers of his staff. His passage through the streets, crowded with the irregular burgher guard, and a ferocious mob, was attended with imminent risk; but at length he reached his own palace, and commenced a conference. Discussions were continued for several days between the prince on one side, and respectable citizens on the other, which were conducted with firmness and in a conciliatory spirit by both parties. The substance was not a rejection of the royal authority, or of the reigning dynasty, on the part of the citizens, but a separation of the administration of Belgium from that of Holland. They all declared that no wish prevailed for any union with France, but only for such a kind of independence for both countries as had been fixed between Sweden and Norway, with which both countries were satisfied and benefited. It was more than intimated to the prince that the wishes of all Belgium would be fulfilled if he were elevated to the throne; but in answer to such suggestions he firmly asked of one of the most influential men both at that and the present time, "What opinion would you entertain of me were I to sacrifice the interests of my father to my own? What confidence could you repose in a man who could cast off his allegiance to his king, and that king his father, merely to gratify his own ambition? I also am a father," added the prince with deep emotion, "and am bound to show a proper example to my children. Posterity shall not revert to my name, and revile me as that disloyal Nassau who tore the diadem from his father's brow to place it on his own."

At a final meeting held on the 3d of September, when many members of the states-general attended, it was so fully obvious to the prince that nothing but a separate administration of the two countries would restore tranquillity, that he resolved to use his influence with his father to accomplish that object; and he received the fullest assurance from the persons present, that they would unite in the most efficacious measures to assure the dynasty of the house of Orange, and to protect the territory of Belgium against any attempts to subject it to France, or any other foreign power. The prince expressed his determination to use his most powerful arguments with his father to obtain his assent to this proposal; but expressed his apprehension that he should be unable to succeed in his endeavours. The prince then quitted the city, carrying with him the respect of all those with whom he had communicated, for the courage he had displayed, for the knowledge of public affairs which he discovered, for the cool judgment which he exercised, and, above all, for the sense of parental duty which he had manifested. Whilst these transactions were passing in Brussels, the whole country was in a flame; in every town the populace were triumphant, and indulged unre-

Belgium. strained in plunder, to which, especially in the important city of Liège, was added the conflagration of several valuable manufacturing establishments. The officers of the army, with no definite orders how to act, were paralyzed in some places, in others gave up their arms, and in others engaged to be neutral.

The king, amidst the general disorder in Belgium, and the most fanatical attachment to the royal cause in Holland, had summoned the states-general from both divisions to assemble at the Hague. The members from Belgium, with some slight hesitation, resolved to repair thither, and the assembly was opened on the 13th of September, by a speech from the king, which was firm and temperate, but by no means definite. The proceedings of this body were dilatory; the Belgium members were treated with indignity and insult by the populace; and the language of some of the Dutch members expressed vengeance rather than conciliation. The accounts received at Brussels from the Hague, and the warlike demonstrations made by the troops, rekindled and accelerated the preparations for defence, and induced some approaches to organization. The burgher guards had become tired of military duty, and being mostly tradesmen living on their business, which had now been ruined, they were anxious for the return of the tranquillity upon which their existence depended. The leaders of the opposition, however, drew fresh recruits of a more determined and more reckless description from the rude population of the Walloon provinces, from the men employed in the coal and iron mines, and from the iron forges and other works which had been destroyed or shut up in and around Liège. These were, in a great measure, old and hardy soldiers, who had served in the ranks of Bonaparte's army, and fought in Germany, in Russia, or in Spain. Their arrival in the capital spread terror amongst the peaceable inhabitants, and kindled alarms lest they should be again exposed to the outrages which had marked the first days of the explosion. The defenders were thus divided into two parties; but, as usual, the most violent soon prevailed; and the council of the rabble soon dispersed that of the burghers (for both had their separate assemblies), seized the arms of the latter, and added to them others which had been collected in different parts of the country.

Although the states were still sitting at the Hague, the king's army was gradually drawn around Brussels. It consisted of 14,000 well appointed troops, under the command of Prince Frederick. But the motions of this powerful body were so dilatory, and its whole operations so unmilitary, that they are difficult to be accounted for, unless on the supposition that the conduct of the king was too conciliatory when force should have been applied, and too hostile when conciliation would have been of most advantage to his cause. On the 20th of September the council resolved to take possession of Brussels, and orders were sent to Prince Frederick to that effect. This resolution was taken at the Hague in consequence of the information of numerous emissaries from Brussels, who represented the inhabitants as eager to receive the troops, and to assist in putting an end to the anarchy and oppression which the mob were exercising. The most respectable names in the city were appended to these representations, which were doubtless sincere, but came from such as were more prepared to enjoy the return of peace and good government than to contribute any share of their personal services to secure these blessings.

On the 25th, the troops advanced towards the city, and with little opposition occupied the upper portion or court part of it, which is situated on a hill, by which the whole of the rest of the town is commanded. The opponents in the lower part of the city were dispirited and disunited, and most of the more violent leaders had fled. But the commanders of the army seem to have been seized with a panic, or to have dreaded doing too much mischief to the houses and property of the more wealthy inhabitants. In the square, where the troops had been drawn up, they were exposed to a galling fire from an invisible enemy, who, from the roofs of the houses, and from the cellars, picked off the officers and men without being much exposed to any return from the troops. Instead of destroying the houses and buildings which concealed the assailants, the prince had recourse to unavailing negotiations, and, after three days of most harassing service, determined to withdraw his troops. He had the means of stopping all supplies from entering the city, and thus of effecting a surrender by starvation; or, by a bombardment, he might have easily enforced submission. Why neither of these means were adopted cannot be certainly known; but the friends of the royal party attribute it to humanity alone. The loss of lives was not very great on the side of the king's troops, considering their exposed situation, and the number engaged. It is stated in the returns as 138 killed, and 650 wounded; whilst of the defenders of the city, though far inferior in numbers, the casualties were acknowledged by themselves to be 450 killed, and 1250 wounded. This disparity must be considered as one of the many extraordinary circumstances of the transactions, and renders the result utterly incomprehensible. The incredible intelligence of this repulse was rapidly conveyed to the provinces, with great exaggerations; and disaffection, anarchy, and demoralisation were spread everywhere. The army retreated towards Antwerp, which, in spite of the force near it, soon became involved in confusion. Ghent, Bruges, Ostend, and the other towns in that direction, immediately became a prey to the revolutionary party, and experienced the horrors of anarchy in the destruction of some of their most extensive manufacturing establishments. The universal rejoicing of the Belgians did not prevent some measures from being adopted to restrain outrages. In a few days, some individuals, with the general acquiescence, formed themselves into a provisional government. They were for the most part men of character and property; but amongst them was De Potter, who had returned as soon as the danger was over, and had been placed by the popular feeling at the head of the body. His power was but of short duration, and he soon fell into utter insignificance, if not contempt, as did others of the original leaders of the insurrection. When those of the representatives who had assembled at the Hague returned home, and their conduct was reviewed in a dispassionate manner, the weight of their character gave them an influence which proved favourable to the return of order. Some of them were added to the body forming the provisional government, and they exercised their influence with prudence, firmness, and integrity. Belgium.

In the provisional government the state of parties was singular, from the variety of opinions. De Potter, who looked forward to the dignity of president, advocated a republican form of government; Gendebeer, a decided advocate of democracy, preferred a union with France; whilst Van de Weyer wished for an independent government, on a monarchical basis, with the Prince of Orange at the head, if he would consent to withdraw altogether from his Dutch obligations, and become exclusively the sovereign of Belgium. The plan of Van de Weyer was known to be favoured by all the kings of Europe; and even France, at that moment under the pilotage of Lafayette, was averse to the entire exclusion of the Nassau dynasty, and sent an agent to Brussels to forward his views. Gendebeer had visited Paris, and there found little or no disposition amongst the leading people to agree to a union with the Belgians, which, they were aware, would involve them in a war with all those powers that had founded the kingdom of the

Belgium. Netherlands in 1815, solely as a European object and a barrier against France.

It soon became evident in Belgium itself that republicanism had made little or no progress. The prevailing opinion was strong in favour of the Catholic religion, with all its ancient powers and observances, but stronger still in favour of a nationality independent of all foreign control. This latter spirit contributed to increase the number of those who had taken up arms; and by such persons the repulse of the Dutch at Brussels was vainly considered as an evidence of the military power of the people. Many of the privates, and a few Belgians of distinction, had been in the army of Prince Frederick; but they soon left his colours, and entered the ranks of their countrymen. The Belgian colours waved on every tower in the country, except those of Antwerp and Maestricht; when the Dutch army, greatly reduced in numbers as regarded subalterns and privates, but with the artillery in complete order, withdrew into their own territory.

The council of the king at the Hague resolved on the separation of the two governments into different administrations; but it was then too late to produce reconciliation; and an attempt made by the Prince of Orange to procure for himself the supremacy of Belgium had no other effect than to beget contempt in that country, and to draw upon himself the temporary suspicion of double dealing towards his father and his countrymen in Holland.

The transactions which took place at Antwerp in October had the further effect of rendering the Belgians still more adverse to the Orange dynasty than they had before been. That city was invested by a Belgian force, whilst within, notwithstanding the resistance of the armed burghers, the populace became masters of the place; and the citadel was occupied by a garrison of 8000 good troops, commanded by the bravest of the Dutch officers, General Chassé. A truce had been concluded between the adverse parties, and a white flag hoisted from the fort; but the Belgian officers were unable to maintain it, the populace having begun an attack on the citadel, though with no other arms than muskets. This was not returned, but a cannon was brought forward by the populace, and a fire opened on the gates of the citadel, which, as the Belgian officers assert, was without their approbation or knowledge. On this infraction of the truce, Chassé ordered two or three guns to be fired from the bastion facing the arsenal. This being found ineffectual, the white flag was taken down; a signal was made to the fleet, consisting of eight vessels of war, in the Scheldt, close to the town; and a cannonade and bombardment commenced. It was more terrific than injurious, the fire being chiefly directed against the arsenal and the entrepôt, where all the military and naval stores in the former were destroyed; whilst in the latter large quantities of sugar, coffee, hides, cloths, silks, and spices, were burned and buried in the ruins of the storehouses. The firing had continued some hours when a deputation from the city made their way to the citadel, and proposed a suspension of hostilities, which was instantly agreed to, and the firing ceased. Never, perhaps, was exaggeration or misrepresentation carried farther than on this occasion, in the reports printed and circulated through Belgium; and the effect which they produced destroyed the last hope of those who wished well to the Orange dynasty. Since that event, official accounts made out by the Belgian custom-house show, that the whole loss of goods in the stores amounted to 1,888,000 florins, or L.157,200; whilst the damage done to private buildings, and the furniture in them, amounted to 679,466 florins, or L.59,450. In this the loss of the public buildings was not included. The number of the killed was only sixty-eight, of whom seventeen were military men, and the others those of the populace who had caused the calamity. The Dutch asserted that the fire was confined almost wholly to the spot where the munitions of war were stored, and that the rest Belgium. of the city was designedly spared.

As all hope of conciliation was thus destroyed, the court of the Hague made pressing solicitations to the four powers who by treaty had formed the kingdom of the Netherlands, to fulfil the obligations imposed upon them by the treaty of Vienna of 1815. But it was soon seen by the answer of Lord Aberdeen, the British secretary of state, and by those of the ministers of the other powers in succession, that none of them was disposed to make use of any other than pacific measures. This proceeding gave rise to negotiations between the allied powers, which were chiefly carried on in London, out of which proceeded numerous protocols, which had no decisive influence on the course of events. The public affairs of Europe favoured the independence of Belgium. All the powers were in alarm at the recent events in France, and all feared, not that the scarcely seated king would willingly commence a war of aggression, but that the democratic party might become sufficiently powerful to compel him to associate himself with the Belgians, and to bring that country under the power of France. The obvious interest of the four great powers was tranquillity, and the securing of the Continent against Flanders becoming the base of military operations towards the centre of Europe. If these could be obtained, it mattered little whether they arose from the junction or the separation of the two portions which had formed the kingdom of the Netherlands. The first meeting of the ministers of the great powers showed that they merely considered themselves as arbitrators between the northern and southern divisions of the newly-dissolved kingdom; and their first measures were addressed to the object of a suspension of hostilities, which was to a limited extent acquiesced in by both parties.

To settle the internal government now became the first object of the Belgians, who considered their independence as firmly assured. A national congress was accordingly assembled at Brussels, consisting of two hundred deputies, chosen in the several provinces, from all tax-paying persons above twenty-five years of age, without exception as to religion. The qualification for the electors and the elected was the paying of taxes, which varied in the several provinces according to their estimated wealth. Thus, in Luxembourg, the poorest province, the qualification was the payment of taxes annually to the amount of twenty-one shillings and sixpence; but from this the required rate was gradually raised, till, in Flanders, the richest of the provinces, the tax paid required to be six pounds five shillings. The assembly was a fair representation of the people of Belgium; for scarcely any proprietor was excluded from voting, whilst in the larger towns and cities the mere populace, from the qualification being higher, had not the means of introducing their favourites. As soon as the assembly met, the demagogues, who had contributed to the revolution, became insignificant. De Potter, Thielman, and the others who had been martyrs and heroes with the mob, sunk into insignificance.

The assembly proceeded to business in a regular manner. Three important propositions were presented to the congress. The first was the declaration of independence, which was voted unanimously; the second, proposed on the 22d of November, decided against a republic, and in favour of a constitutional hereditary monarchy, by a majority of 174 against thirteen votes, but it did not fix on the title of the future chief of the state; the third proposition, brought forward on the 23d, was for the perpetual exclusion of the Orange Nassau family. This was debated during two days, and at the close was agreed to by a majority of 161 against twenty-eight. The object of the minority was to delay the proposition till a more cool and distant period, and till it could be known whether the revolution which had taken place would lead to a war against Belgium. Mr Van de Weyer had, however, returned from a mission to London,

Belgium. and it was commonly believed he had ascertained that the sentiments of Lord Grey and the new ministers were as averse to any warlike interference as those which had been previously expressed by the Duke of Wellington and Lord Aberdeen.

It seems probable, that at the period in question the governments of England and France were co-operating in endeavours to place the Prince of Orange on the throne of Belgium; even if it could be accomplished in defiance of the positive declaration of the king his father, who did not scruple to assert, "that he would rather see De Potter placed on the throne than the Prince of Orange." But if such was the desire of the two kingdoms, it was soon discovered to be utterly impracticable, though much time was spent under the impression of its feasibility, and much suspicion excited amongst the Belgians against the sincerity of France.

Whilst the plenipotentiaries were settling the most equitable plan for separating the two countries, and had given their view with respect to the boundaries of each, they also adjusted what portion of the debt of the Netherlands should be assigned to Belgium, and what to Holland, fixing the former at $\frac{16}{31}$ parts, and the latter at $\frac{15}{31}$ parts. These discussions led to others: and it soon became known, that however independent Belgium might become as regarded Holland, it was too dependent on the superior power of the European kingdoms to be permitted the spontaneous nomination of the individual who was to become its sovereign. At that time a large, perhaps a predominant, party in the assembly would have preferred one of the Bonaparte family; but this, it soon appeared, would not be permitted by France. Another party were inclined to select a son of Louis Philip, the king of the French; but intimations had been communicated to that prince, that England would consider an acquiescence in the project as a sufficient cause of war; and he agreed to the exclusion of his son, but so privately that it was only known to a few individuals beyond the diplomatic circles. The partisans of the house of Orange took no open and avowed part in these discussions.

The inefficiency of this representative assembly to the real purposes of a government was speedily shown in the long and bombastical speeches of the members; in the absolute confusion in every department, whether civil, military, or judicial; and in the mobbing and plundering which prevailed in all the provinces. The necessity for an executive power was so strongly felt by the more reflecting members of the assembly, that after several days' preparatory debate, it was resolved, on the 19th of January 1831, to proceed to the election of a chief on the 28th of that month. The election of a sovereign, or rather of a dynasty, was enough to kindle agitation and intrigue; but perhaps less of these than might have been expected was discoverable, from the great number of the candidates whose pretensions were urged. On the day before the election, petitions were presented to the assembly in favour of Lafayette, Fabvier, Chateaubriand, the Prince of Carignan, the Archduke Charles; Surlet de Chokier, Charles Rogier, and Felix de Merode, private Belgians; Prince Otho of Bavaria, John duke of Saxony, a Prince of Salm, the Pope, the Duke of Nemours, second son of Louis Philip, and the Duke of Leuchtenburg. Besides these, the Duke of Lucca, the Duke of Reichstadt, the son of Napoleon, and the Prince of Capua, brother of the king of the Two Sicilies, were suggested. The choice of the last was seriously contemplated by the French, through Talleyrand; but the Belgians showed no predilection for him, although he was not objectionable to any of the four powers. Had the Belgians showed any decided eagerness for Prince Otho of Bavaria, it was known that he would have been recognised by England, France, and Prussia; and that he would then have obtained the hand of the Princess Mary, third daughter of the king of the French. But his age, for he was only fifteen, formed an objection with the Belgians. The popular press, decidedly democratic, was most united in favour of the Duke of Leuchtenburg; but its power had been used till it was exhausted; and, besides, the choice was in better hands than those who are influenced by its inflammatory declamations. It is remarkable, that amongst the long list of candidates the name of Prince Leopold was never once mentioned. It has been suggested that England had not even then abandoned the hope of fixing the Prince of Orange on the throne. This would have been approved of by Russia, Prussia, and Austria, and by the nobles and wealthier part of the Belgians, but not by France, as Louis Philip was disposed to fear that the example of enthroning the son of the deposed monarch might hereafter have been taken as a precedent in favour of the Duke of Bordeaux against his son in France. Belgium.

At the eve of the election, however, by some strange caprice of circumstances, all the names were withdrawn excepting the two, who, all intelligent persons knew, could not be allowed to rule. It was remarked of them by Northomb, one of the most respectable of the democratic members, that "the Duke of Leuchtenburg was essentially anti-French, without being European, whilst the Duke of Nemours was so exclusively French as to be directly anti-European." It is singular that both these personages had been declared inadmissible by the conference of the representatives of the great powers. The name of the Archduke Charles of Austria was then brought forward; but he could only be considered as a cloak for the partisans of the Prince of Orange, and for other members, who knew he would not accept the dignity, for the purpose of reducing that absolute majority of the whole voters which was necessary to the choice. The votes were taken by ballot, and the following result appeared when the names were drawn from the urn:—The total number of voters was 191, and consequently the required absolute majority was ninety-six. Nine members being absent, there appeared for the Duke of Nemours eighty-nine, for the Duke of Leuchtenburg sixty-seven, and for the Archduke Charles thirty-five, so that, in fact, there was no election. A new voting then became necessary, and the second scrutiny gave a definite result. Another member had entered, making 192, and consequently the absolute majority required was ninety seven. The state of the voting then appeared to be, for Nemours ninety-seven, for Leuchtenburg seventy-four, and for the archduke twenty-one. This annunciation was received with acclamation by the populace, and with expressions of joy by the partisans of the successful candidate, who well knew his father would not permit him to accept the offered crown. A deputation was despatched to Paris to announce the choice. But the throne was refused, and the deputies returned after paying and receiving some unmeaning compliments.

The moment was seized by the partisans of the Prince of Orange in order to raise a commotion in his favour. It was a wild project, confined to Ghent, Bruges, and Antwerp, where his adherents were numerous, especially amongst the lower class, who had been thrown out of employment by the cessation of commerce and manufactures. The attack on Ghent was speedily quelled, and the leader fled; but he was seized on his way to France, and on his person were found letters from the Prince of Orange, then in London, encouraging the project. This unsuccessful effort, and the evidence of the prince's participation in it, proved very injurious to his cause; and even sober men who had favoured him, were disgusted with what appeared to them to be an attempt to involve the country in a civil war.

On the refusal of France, the assembly, still feeling the

Belgium. want of an executive power, passed an act that the throne was vacant, thereby establishing the monarchical principle, and then proceeded to the election of a regent as a temporary measure. The choice fell upon Baron Surlet de Chokier, a worthy, well-meaning man, of no great abilities, who showed little solicitude for the dignity; and on the 25th of February he was installed with some parade. Plots and conspiracies were forming around him in every direction, and the demon of civil war was urging on the people to mutual destruction. The feeble government of the regent could produce neither obedience nor tranquillity within the country; and it was threatened by the Dutch, who adhered to their king and his purposes with equal union and ardour. It was reported, during the regency, that schemes for the dismemberment of Belgium were contemplated by some of the continental powers. According to this project, two thirds of Flanders, the province of Antwerp, and the northern half of Limburg and Brabant, including Brussels, would have fallen to Holland; the eastern part of Luxembourg, with Liège and other territories upon the left bank of the Meuse and the Moselle, would have been transferred to Prussia; and Namur, Hainault, and the west part of Flanders, would have been ceded to France. If this project was seriously entertained, it received such discouragement from the British government, that it was speedily abandoned. About the same period, that is, about a month after the instalment of the regent, extensive plans were formed for a general rising amongst the Orange party, in connection with some of the chief officers of the army and the most influential leaders of the burgher guards of Brussels. But this came to nothing, having, it is said, been discountenanced by the British minister at Brussels, who saw no other effect that could arise from it but a general European war. It is said that after some discussion respecting Luxembourg, and checking the petty hostilities on the frontier, the British government in April gave up all hope of establishing the Prince of Orange on the Belgic throne. On the 12th of that month a kind of proposition was made by some of the influential members of the assembly, and privately communicated to Sir Edward Cust, one of the equerries of Prince Leopold, with the design of ascertaining whether the prince, if chosen, would accept the crown. Leopold answered in the affirmative, but strictly abstained from giving any authority to make exertions in his favour. He was however convinced, before the election, that a vast majority of the electors would vote in his favour; and that he should have all the aid of the clergy and the high Catholic nobility, with no opposition but from the French and movement party, and the few Orangeists that had seats in the assembly. A deputation of four members repaired to Claremont, and had an interview with the prince. They explained their object, and the conditions upon which they were authorized to offer the crown, and awaited his reply. It manifested a noble, simple, and frank disposition, and concluded thus: "All my ambition is to contribute to the happiness of my fellow-creatures. When yet young, I found myself in so many difficult and singular situations, that I have learned to consider power only with a philosophic eye. I never coveted it but for the sake of doing good, durable good. Had not certain political differences arisen, which appeared to me essentially opposed to the independence of Greece, I should now be in that country; and yet I never attempted to conceal from myself the difficulties of my position. I am aware how desirable it is that Belgium should have a sovereign as soon as possible. The peace of Europe is deeply interested in it."

The deputation returned, and many stormy discussions ensued. Attempts were made to defer the election till all differences with Holland were settled; but these were overcome by the votes of 137 to 48. The election took place on the 4th of June, when 152 votes out of 196, four only being absent, determined that Prince Leopold should be proclaimed king of the Belgians. under the express condition, that he "would accept the constitution, and swear to maintain the national independence and territorial integrity." Belgium.

This choice, though not expressly unanimous, was such in reality; for of the minority of forty-three, nineteen voted on the ground that the election was premature, fourteen voted for Baron Surlet de Chokier, solely on account of private friendship, and thus the real opposition to Leopold consisted only of ten. Though the voting was by ballot, yet the vote of every man was known; and all who dared, gave reasons for it, except the ten, who were well known as terrorists.

Leopold lost no time in repairing to the post to which he was appointed, and, with only one aide-de-camp and a few domestics, landed at Ostend on the 17th of June, and proceeded directly through Ghent to the palace of Lacken, near Brussels. He made his public entry into that city on the 21st, and was received with cordiality by the higher classes, and by the populace with loud acclamations. The king took the oath to the constitution; the regent delivered up his power; and the congress was dissolved, to make way for the election of the members who were to form the two legislative chambers, as prescribed by the fundamental laws.

The first chamber, or the senate, was to consist of fifty members, chosen for eight years, but one half of them was to be renewed at the end of four years. The qualifications were to be, having attained the age of forty years, and paying direct taxes to the amount of 1000 florins, or L.84 yearly. The second chamber was to consist of 101 members, being at the rate of one for 40,000 inhabitants. They were to be of the age of twenty-five years, to pay annual direct taxes to the amount of L.8, and to be paid at the rate of 200 florins, or L.16, each month during the session. They were to be renewed by one half retiring at the end of two years, but they might be again elected.

After a few formalities, and appointing the ministers to compose the cabinet, on the choice of which much judgment was exercised, the king left the capital to visit Antwerp, Liège, and the other parts of the new kingdom, and was everywhere received with demonstrations of respect and of loyalty. But whilst the proceedings just narrated were passing in Belgium, a storm was gathering on the side of Holland, which had not been anticipated, and to meet which no adequate preparations had been made. The Belgians relied on the armistice which the conference of the ambassadors had established, and the few measures which were taken by them discovered only the confusion and disorder inseparable from all popular movements. In Holland, every thing betokened tranquillity, order, and loyalty. The different orders of the government and the people were more eager for punishing what they denominated the rebellion, than even the king and his family. A powerful army was quickly assembled. It was well disciplined, officered, and appointed, and furnished with an ample train of artillery; and yet all was done with so much secrecy, that till that army was ready to advance beyond the frontiers, no preparation was made to resist it.

Much dispute has arisen relative to the right of Holland to commence hostilities without due notice of the cessation of the armistice; but, on the other hand, Holland maintained that due notice had been given. The whole turned on the precise sense of the words "ses moyens militaires," in a note delivered by the Dutch ministers to the conference of ambassadors. The king was certainly encouraged in the enterprise by the stormy scenes exhibited in the Belgian assembly between the period of Leopold's election and the time of his arrival. By the noxious influence of the press, such angry passions had been kindled in every

Belgium. division of society, as seemed to threaten internal war; but happily a most powerful speech of Mr Lebau in favour of union, and urging the importance of rallying round their new monarch, had the effect of producing feelings of tranquillity; though no language had power to produce order or infuse energy, when the time approached for the exhibition of the one and the exercise of the other.

The Prince of Orange having assumed the command of the Dutch army at Breda, on the 1st of August, the order to advance was instantly given; and the march of the several divisions commenced the next day. This was a complete surprise to the Belgians, who were unprepared at every point to resist a disposable army of more than 40,000 men. It is not necessary here to describe the position and the movements of the various corps on both sides. It was, however, remarked by military men, that the Prince of Orange advanced more deliberately than the occasion required. Leopold collected his forces, such as they were, near Louvain, in order to cover his capital. In this position the Dutch army, having seized the road which led to Brussels on the 9th of August, advanced to attack him. The Belgian troops could not stand for a moment against their opponents, but instantly fled, throwing away their arms, and escaping in disorder; and a neglect of the Dutch, who thoughtlessly left open a road behind Louvain, alone prevented Leopold and his whole staff from becoming prisoners of war. He, however, made good his retreat to the capital, upon which all hostilities ceased. As soon as the movements of the Dutch were known, Leopold appealed to France for assistance. A French army was cantoned on the frontiers, which, by telegraphic communications, was instantly set in motion; and intelligence of their advance was formally announced to the Prince of Orange by Lord William Russell, coupled with an intimation, from the French marshal Gérard, of the determination of the two powers to enforce the abandonment of all military operations. As the French army rapidly entered the country, the Prince of Orange soon saw the necessity of retreating; and a convention was concluded between him and the French general, in consequence of which he returned to Holland, and the French repassed the frontier; so that by the 1st of September both armies had left the Belgian territory.

The cowardly disgraceful conduct of the Belgic troops was of great benefit to the new government. It showed the reflecting part of the community the folly of trusting the defence of their country to a host of popular partisans, too ready to destroy or to plunder, but too much inflated by the flattery they bestowed on themselves to become efficient defenders when steadily opposed. All saw the necessity of confiding in their chief, and became convinced that a regular army must be formed, in which the men should be compelled to obey their officers. The formation of an army was therefore determined on; but Belgium could not furnish officers. Most of those appointed had been placed in stations of which they were unworthy, because they had been what was called distinguished patriots, that is, leaders of the revolutionary movements; but those active disorganizers were found worse than useless when energy against an enemy required order, discipline, and obedience. By the interference to protect Belgium against Holland, this farther advantage was gained, that the protecting powers were placed in a position to obtain more weight in the negotiations carried on in the conferences of the ambassadors, and both parties were more disposed to leave the contested points respecting boundaries to their arbitration.

In forming an army, Leopold was assisted by the French, who, as far as could be done, furnished it with able officers; a want which Belgium could by no means supply from the natives of that country. The partisans of the Orange family, on this occasion, justified the conduct of King William previous to the revolution, in having selected few of his officers from the Belgians. The selection of Frenchmen, they contended, proved that William was right in not trusting to officers taken from that division of his kingdom. Belgium.

After the Dutch irruption, Leopold proceeded with coolness and vigour to restore order and gain confidence. He kept on the best of terms with the most important party, the Catholic clergy and the Catholic nobility, and avoided any nearer contact with the French party than politeness and civility required. He knew who were the real friends of monarchical government, and his best supporters. His marriage with a daughter of the king of the French, who was a Catholic, and the contract that the children of the marriage should be educated in the Catholic faith, were powerful means of attaching to his throne all those of his subjects who were under the influence of the clergy. The Belgian army, under the French officers, soon attained considerable advancement in organization and discipline. The undisciplined free troops were disbanded, and the best of the men incorporated in the regiment of chasseurs. Some superior officers were superseded, and many of the subalterns dismissed. A military school was established, and a corps of sappers and miners with a pontoon brigade raised.

The civil list was arranged with economy and order, and the other branches of the public service reformed, and others newly arranged. The talents and the integrity of Leopold, and his benevolent disposition, made a very favourable impression on all that approached him.

Whilst affairs were thus proceeding within, the great work of general pacification was attended to by the members of the conference in London. A final decision was come to on the 15th of November, expressed in twenty-four articles. These settled the great point of boundaries, and placed the question of Luxembourg in a way the most favourable, as was thought, for future pacific arrangement; but, above all, it expressed a determination "to oppose, by every means in their power, the renewal of hostilities between the two countries." This arrangement was ratified by the Belgian and French sovereigns on the 20th and 24th of November, by the British on the 6th of December, by Austria and Prussia on the 18th of April 1832, and by Russia on the 4th of May.

By these articles, the division of the joint debt was fixed on the scale before arranged, viz. $\frac{1}{31}$ for Belgium, and $\frac{5}{31}$ for Holland; but as the latter had discharged the whole interest as it became due from the first disturbances, she was to be paid the share of the advances, with interest on them at the rate of five per cent. Another point arose out of the settlement of the limits of the two countries Holland was to have Maestricht, and was in actual possession of that place and its citadel; but Antwerp, which was allotted to Belgium, and was in possession of the Belgians, was commanded by the citadel, which was garrisoned by a Dutch army under the command of General Chassé, a distinguished officer, who, after the annexation of Holland to France, had served in the army of the Emperor Napoleon. The Belgians had given only a conditional ratification of the articles of the 15th of November, upon the express stipulation that the whole of them, in which the possession of the citadel of Antwerp was certainly included, should be fulfilled. They were precluded by that instrument from exercising hostilities, and therefore claimed from the parties to it the performance of its conditions.

It was important to the allied powers that the throne which they had established in the person of Leopold should be strengthened in the views of his subjects, who had sometimes manifested dispositions to democracy, and at others strong inclinations for a union with France, neither of which were deemed compatible with the interests of the European commonwealth. But it could not retain respect if the con-

Belgium. ditions framed by the founders were to be impugned by the Dutch holding the citadel of Antwerp, whilst they were still in possession of Maestricht. These considerations had their due effect on the conference, who, on the 1st of October, unanimously resolved that forcible means were necessary. They differed in regard to the means, the northern courts wishing to adopt pecuniary coercion, by deducting from the debt due from Belgium to Holland a sum weekly till the fortress was delivered up; but to this France and England objected, as leading only to future and tedious negotiations, during which Rotterdam and Amsterdam might enjoy those exclusive commercial advantages which Antwerp was entitled to share with them.

Belgium, being wearied with these entangled negotiations, and having now created an army of more than 100,000, gave notice that, unless their territory was evacuated before the 3d of November, they would use force to compel it. But this would have created a war, which all the powers were anxious to prevent. On the 22d of October, a convention was therefore entered into between England and France, which was forthwith communicated to the three other powers, of whose passive adhesion they were assured.

By this convention it was determined, that if the places assigned by the former resolutions to the respective parties were not given up before the 12th of November, France and England would enforce the delivery of these places. This determination was communicated to both nations. Belgium was ready to give up Venloo, which she held; but Holland positively declined surrendering the citadel of Antwerp. The result was, that a combined fleet of English and French proceeded to blockade the ports of Holland, and detain the merchant-ships, whilst France prepared an army to besiege the citadel, without allowing the Belgians in any way to interfere in the military operation. The siege of Antwerp by the French, as a fine practical exemplification of science, became an object of great interest to the military amateurs of all Europe, who repaired thither as spectators. But this is not the place for recording the history of that warlike spectacle. It was vigorously and skilfully attacked; and the defence, which was altogether passive, exhibited a conspicuous example of fortitude and endurance. The first works of the besiegers were opened on the 30th of November, and on the 24th of December the citadel capitulated, when the garrison marched out, and the French took possession of the battered fortress, which, on the 1st of January, they delivered up to the Belgians. The city of Antwerp was not in the least injured, as the approaches were carried on upon the opposite side. The French army shortly afterwards withdrew from Belgium to its own territory. The Dutch garrison was marched into France as prisoners, on the ground that two forts on the river Scheldt, those of Lillo and Liefenschoeck, were still retained by the Dutch. This led to long and complicated diplomatic negotiations, which were at length adjusted, when the captured garrison returned to their own country. On the 16th of May 1833 an indefinite armistice was agreed upon, and on the 21st a provisional convention was signed, which preserved the liberty of the Scheldt, regulated the tolls of the Meuse by the tariffs of Mayence, maintained the existing territorial arrangement, including therein Luxembourg, raised the embargo on the Dutch ships, and set at liberty all the Dutch prisoners kept in France since the siege of Antwerp. Nevertheless, the house of Orange still numbered many partizans among the people, and when the government sequestrated its possessions in Belgium murmurs were heard in many towns, chiefly at Ghent, Liège, Antwerp, and Brussels. The people thus irritated became violent; at Brussels they pillaged the houses of the principal Orangists, and were appeased with difficulty. All the attention of the government of King Leopold was given to the encouragement of Belgian commerce, which the revolution had almost annihilated. In 1838 a financial crisis endangered the bank, which was constrained to suspend its payments. The government, however, came to its aid, and soon restored public confidence. Belgium.

On the 14th of March of the same year, Holland signified readiness to accept the treaty of the twenty-four articles. This announcement produced an extraordinary movement in the kingdom, for since the year 1830 Luxembourg and Limbourg were identified with Belgium, and sent representatives to both chambers; addresses were sent to the government from all parts of the country, the Brabant colours were hoisted, and the people were roused by protestations of the most energetic kind. Leopold was in the meanwhile obliged to yield to the representations of Prussia and Austria, and in 1839 the Belgians had to abandon more than one-third of the provinces of Luxembourg and Limbourg. A subsequent treaty was formed on the 19th of October 1842, which had for its object the settlement of the debts chargeable against Holland and Belgium. By this it was agreed that Belgium should only be liable for an annual payment of five millions of florins, instead of eight millions four hundred thousand florins, which had been imposed upon it by the treaty of November 15. 1831.

In the same year was discovered a conspiracy to place the Prince of Orange upon the throne. The generals Vandermeer and Vandersmissen were at the head of this movement. They were tried before the tribunals, and condemned to death, but the king commuted their punishment to twenty years' imprisonment. Vandersmissen effected his escape, and Vandermeer was afterwards pardoned on condition of retiring to America.

During the revolutions and insurrections of 1848, Belgium was one of the few European kingdoms in which tranquillity was maintained, for which it was mainly indebted to its constitutional government and the wisdom and liberality of its sovereign. On the 11th October 1850 the queen Louise died, leaving two sons and a daughter.

Situation and extent. Belgium extends from Lat. 49. 27. to 51. 30. N. and from Long. 2. 34. to 6. 4. E. On the N. it is bounded by Holland; E. by Dutch Limbourg and Luxembourg, and Rhenish Prussia; S. by France; and on the W. by the North Sea. It is somewhat of a triangular form, of which the longest side is that adjoining France, being 366 miles in length. The eastern boundary is 233 miles, and the northern and western are together 279 miles in length. Its greatest length from N.W. to S.E. (from Ostend to Arlon) is 56 leagues of 5000 metres, or 174 English miles, and its greatest breadth from N. to S. is 105 miles. It has an area of 2,945,593 hectares, equal to 7,278,968 English acres, or 11,373 square miles; being about one-eighth of the area of Great Britain. This country is divided into nine provinces—Antwerp in the N.; West and East Flanders and Hainault in the W.; Namur in the S.; Luxembourg in the S.E.; Liège and Limbourg in the E.; and Brabant in the centre.

Physical description. Belgium is in general a very flat country with few elevations, and these rarely exceeding 2000 feet in height. They are principally to be found in the E. and S.E., while the N. and N.W. parts of the country bear a considerable resemblance to Holland. The elevations of Belgium take their rise in France, and extend generally in a N.E. direction. A chain proceeding from the neighbourhood of the sources of the Saone separates the waters of the Meuse from those of the Moselle, passes Arlon and Neufchateau, then extends in a north-eastern direction towards Bastogne, and finally enters Prussia. A branch of this chain goes off at Neufchateau, proceeds northward towards Liège, passes St Hubert, and separates the Ourthe from the Meuse. A part of the Ardennes also extends into Belgium, and separates the basin of the Meuse from that of the Scheldt. It pro-

Belgium. ceeds in a north-eastern direction, passing Fontaine l'Eveque, Gembloux, Ramillies, and Tongres, then, gradually decreasing in height, it turns northward to Asch, and afterwards N.W. to Hechtal, Lommel, and Turnhout. A series of heights on the frontier of France, near Chimay, extend in a N.W. direction towards Namur, and separate the Meuse from the Sambre.

The provinces of Liège, Luxembourg, and Namur present the greatest irregularities of surface. This part of the country is intersected by numerous ravines and streams with steep and rocky banks, by deep valleys, and by ridges of hills, with frequently precipitous and rocky escarpments. The vegetation here is of a very poor and languid character. The greater part of this region is covered with dense forests, marshy and uncultivated plateaux, or wretched pasture land, and corn is very rarely cultivated. The inhabitants are a primitive and pastoral race, principally engaged in the tending of flocks, which constitute their chief riches. Descending towards the coast the forests become less frequent and extensive, and rye, oats, and potatoes take the place of the pasture land. In the western and north-western provinces are extensive and well-watered plains which, from their great fertility and the high state of their cultivation, are the boast of the Belgians and the admiration of strangers. Even here, however, are to be seen occasional patches of waste land and uncultivated heaths, particularly in the provinces of Antwerp and Limbourg. From the improvements which have been going on lately, it is expected that at no distant period these shall have all disappeared.

Polders. In the provinces bordering on the sea, the land is in some places so low as to require to be protected from inundation by dikes. Those places are called *polders*. Numerous places along the banks of the rivers are also protected by embankments; these are called *interior polders*. About a sixtieth part of the kingdom is thus artificially gained from the sea and rivers, being 50,000 hectares, or 193 square miles.

The coast of Belgium is said to be undergoing a change similar to that of Scandinavia,—in some parts a gradual elevation, and in others a gradual depression. Nieuport is said to be the axis of this change, from which, northward to the mouth of the Scheldt, the sea is continually gaining upon the land, while southward to Pas de Calais it is losing.

Rivers. This country is watered by the rivers Scheldt, Meuse, and Yzer, with their tributaries. The Scheldt is navigable during its entire course through Belgium, and has a general direction from S.W. to N.E., passing through the province of Hainault, along the eastern boundary of West Flanders, traversing East Flanders, and finally forming the boundary between the provinces of East Flanders and Antwerp. Its entire length through Belgium is 108 miles. The Meuse has a course nearly parallel to that of the Scheldt, traversing the provinces of Namur, Liège, and Limbourg. It is 115 miles in length, during the whole of which it is navigable. The small river of Yzer, which enters the sea at Nieuport, is navigable for about 26 miles. The navigable rivers connected with the Scheldt are,—the Dyle, which after receiving the Nethe at the village of Rumpst, takes the name of Ruppel, and joins the Scheldt nearly opposite to Ruppelsmonde; the Great and Little Nethe, which after their junction take the name of Nethe and fall into the Dyle; the Demer, also an affluent of the Dyle; the Dender, which enters the Scheldt at Dendermonde; the Durme, which joins it near Thielrode; and the Lys at Ghent. The entire navigable length of these streams is 230 English miles. The navigable rivers of the Meuse are: the Amblere and the Vesdre, affluents of the Ourthe; the Ourthe, which joins the Meuse at Liège; and the Sambre, which joins it at Namur. The navigable length of these is 142 miles. The small river of Yperlee, which joins the Yzer, is navigable for about nine miles. The principal other rivers are the Senne, Belgium. the Haine, the Semoy, and the Lesse.

Canals. Besides these navigable rivers, Belgium has a number of canals for inland navigation, some of which are used also for irrigation. They are 29 in number, and their entire length is 605,440 metres, or 376 English miles. The principal of these are,—the canal from Bruges to Ostend, that from Brussels to Charleroy, from Bocholt to Herenthal, from Brussels to Willebroeck, from Ghent to Bruges, from Liège to Maestricht, from Maestricht to Bois-le-Duc, from Pommeroeul to Antoing, from Plasschendaele to Nieuport, the Louvain canal, the Lieve, and the Moevaert. Each of these canals is upwards of 12 miles in length, and the longest, that from Brussels to Charleroy, upwards of 46 miles. The entire length of the river and canal navigation of Belgium is therefore 1006 English miles.

Mineral springs. Belgium possesses a number of mineral springs, the principal of which are the hot springs of Chaudfontaine, situated about five miles from Liège, and the mineral spring of Tongres See LIÈGE and TONGRES. But the most celebrated waters are those of Spa, of which an account is given under that head. See SPA. The ferruginous springs of Huy were formerly in considerable repute, but are now little used.

Climate. The climate of Belgium is considered as very similar to that of England, and is more temperate and salubrious than that of Holland. In the south-eastern parts the atmosphere is more pure and bracing than in the lower parts towards the N.W., where it is frequently damp and hazy. Frost rarely appears before the middle of October or after the middle of April. From observations made at Brussels for the eighteen years preceding 1851, the mean annual temperature was found to be 50°·3 Fahr.; the maximum mean being 55°·8, and the minimum 43°·5 Fahr. During that period there were no frosts in the five months from April to October, and only twice snow in May and three times in October. The average number of foggy days annually was 58·1, and with thunder 13·2. The annual average of rainy days was 191·4; the quantity being 27·9 inches. The average annual fall at Greenwich during the last 37 years was 27·1 inches.

Civil state. Since the formation of Belgium into an independent state, the government has taken a laudable interest in all that concerns the happiness and improvement of the people; and not being trammelled by a respect for old laws or useless customs, they have adopted as far as possible the most improved systems of other countries. The whole system of government is based upon the broadest principles of rational freedom and liberality; all power emanates from the people, and can only be exercised according to law. The people are upon a strict equality in the eye of the law, personal liberty is guaranteed to all, as well as entire freedom in opinion and in religious worship. All the religious sects are endowed by the state, and large grants are also given annually for educational and charitable purposes. Home is inviolable, nor can any one be deprived of his property unless for the good of the state and for a suitable indemnity. Justice is open to all, as well as the means of education, and the benefits of the public charities. The press is free, and civil death is abolished. Any one may address petitions to the public authorities, signed by one or more persons. Trial by jury is established for all criminal and political charges, and for offences of the press. The contents of letters are inviolable, and the post-office is responsible for all letters committed to it.

Government. The government is a constitutional representative and hereditary monarchy. The legislative power is vested in the king, the chamber of representatives, and the senate. The judicial power is exercised by fixed tribunals, freed from all authoritative influences, judging publicly and assigning reasons for their decisions. The provincial and communal affairs are managed by local councils chosen by the people.

King. The royal succession is in the direct male line in the order

Belgium. of primogeniture, to the exclusion of females and their descendants. The king's person is declared sacred; and his ministers are held responsible for the acts of the government. No act of the king can have effect unless countersigned by one of his ministers, who thus becomes the responsible party. The king convokes, prorogues, and dissolves the chambers, and makes rules and orders necessary for the execution of the laws; but has no power to suspend or dispense with the execution of the laws themselves. He nominates to civil and military offices, and commands the sea and land forces. He declares war, and concludes treaties of peace, of alliance, and of commerce, communicating the same to the chambers as far as may be consistent with the interest and safety of the state. Those treaties which may be injurious to the state or to the individual interests of the people can only have effect after obtaining the sanction of the chambers. No surrender, exchange, or addition of territory can be made except when authorized by a law passed by the chambers. In no case can the secret articles of a treaty be destructive or contrary to the patent ones. The king sanctions and promulgates the laws. He has the power of remitting or reducing the punishments pronounced by the judges, except in the case of his ministers, to whom he can extend pardon only at the request of one of the chambers. He has the power of coining money according to law, and also of conferring titles of nobility, but without the power of attaching to them any privileges. In default of male heirs the king may nominate his successor with the consent of the chambers. On the death of the king the chambers assemble without convocation at latest on the tenth day after the decease. From the date of the king's death to the administering of the oath to his successor or to the regent, the constitutional powers of the king are exercised in the name of the people, by the ministers assembled in council, and on their own responsibility. The regency can only be conferred upon one person, and no change in the constitution can be made during the regency. The successor to the throne, or the regent, can only enter upon his duties after having taken an oath, in presence of the assembled chambers, to observe the constitution and the laws, to maintain the independence of the nation and the integrity of its territory. If the successor be under eighteen years of age (which is declared to be the age of majority), the two chambers meet together for the purpose of nominating a regent during the minority. In the case of a vacancy of the throne, the two chambers, deliberating together, nominate provisionally to the regency. They are then dissolved, and within two months the new chambers must assemble, which then provide definitively to the vacancy.

Chambers. The people are represented in the legislature by the Chamber of Representatives and the Senate, the members of which are chosen by the people. The sittings are public; but by the decision of the majority either chamber may form itself into a private committee. No one can at the same time be a member of both chambers, and no member can retain his seat after obtaining a salaried office under the government except on being re-elected. No member can be called in question for any votes or opinions he may have given in the performance of his duties. No member can be prosecuted or arrested during the session, without the consent of the chamber of which he is a member, except in the case of flagrant offence. Each chamber determines the manner of exercising its own powers, and every session nominates its president and vice-presidents, and forms its *bureau*. No petition can be presented personally; and every resolution is adopted by the absolute majority, except in some special cases, when two-thirds of the votes of the members are required to be favourable; in the case of an equality of votes the proposition is thrown out. The chambers meet annually in the month of November, and ought to sit for at least forty days; but the king has the power of convoking them on extraordinary occasions, and of dissolving them either simultaneously or separately. In the latter case a new election must take place within forty days, and a meeting of the chambers within two months. An adjournment cannot be made for a period exceeding one month without the consent of the chambers. Belgium.

Chamber of Representatives. The Chamber of Representatives is composed of deputies chosen directly by the people paying a certain amount of direct taxes. The number of deputies is fixed according to the population, and cannot exceed one member for every 40,000 inhabitants; at present they amount to 108. The members represent the nation generally, and not merely the province or division by which they are nominated. To be eligible for a member it is necessary to be a Belgian by birth, or to have received the grand naturalization; to be in the possession of the civil and political rights of the kingdom; to have attained the age of twenty-five years; and to be resident in Belgium. The members not residing in the town where the chamber sits receive during the session an indemnity of 200 florins (L.16, 13s. 4d.) each per month. The members are elected for four years, one-half going out every two years, except in the case of a dissolution, when a general election takes place. This chamber has the parliamentary initiative and the preliminary vote in all cases relating to the receipts and expenses of the state, and to the contingent of the army.

Senate. The electors of the Chamber of Representatives have also the nomination of the members of the Senate. To be eligible as a senator it is necessary to be a Belgian by birth, or to have received the grand naturalization; to be in the enjoyment of civil and political rights; to be domiciled in Belgium; to be forty years of age; and to pay at least 1000 florins (L.84) of direct taxes. In those provinces where the number of those paying 1000 florins of taxes does not amount to one in every 6000 inhabitants, this proportion is made up by those paying the highest amount below that sum. The permanent deputation of the provincial councils annually prepare a list of those who are eligible to the senate. In 1850 the number of these was 726, of whom 405 were paying the prescribed amount of taxes, and 321 were supplementary. At the age of eighteen the heir-presumptive to the throne has a seat in the senate, but has no voice in its deliberations till he attain the age of twenty-five. The senators receive no indemnity. They are elected for eight years, one-half going out every four years, except in the case of a dissolution. The senate is composed of half as many members as the chamber of representatives, the number at present being 54.

Electors. The amount of direct taxes paid in order to qualify one to be an elector is fixed by the electoral law. The standard varies in different localities, but can never be below 20 florins (33s. 4d.), nor above 100 florins. At the last general election which took place in 1848, the number of electors, voters, &c., in each of the provinces was as follows:—

Provinces.	Electors.	Voters.	Representatives.	Senate.	Electors p. 1000 Inhabitants.
Antwerp, ...	8,229	5,298	10	5	20·25
Brabant, ...	15,333	10,067	17	9	22·21
West Flanders,	10,359	7,554	16	8	16·12
East Flanders,	15,088	9,669	20	10	19·06
Hainault, ...	12,412	8,074	18	9	17·34
Liège, ...	8,090	5,200	11	6	17·90
Limbourg, ...	2,918	2,275	5	2	15·70
Luxembourg,	2,722	2,011	5	2	16·62
Namur, ...	3,925	2,797	6	3	14·90
	79,076	52,955	108	54	18·24

A partial election of representatives took place in 1850, viz., for the provinces of Antwerp, Brabant, West Flanders, Luxembourg, and Namur. The number of electors, &c., was:—

Provinces.	Electors.	Voters.	Representatives.
Antwerp, ...	8,525	7,060	10
Brabant,.....	15,030	10,264	17
West Flanders,	10,162	7,746	16
Luxembourg,...	2,711	1,921	5
Namur, ...	4,007	3,159	6
	40,435	30,150	54

Ministers. The king appoints and dismisses his ministers at pleasure. No member of the royal family can be a minister, nor any but a Belgian, or one who has received the grand naturalization. Ministers have a right of admission to the chambers and to demand a hearing; but have no voice in the deliberations unless they are members. The chambers can at any time demand the presence of the ministers. No act or writing by the king can free a minister from responsibility. The chamber of representatives has the power of accusing the ministers, and of bringing them before the court of cassation, which alone has the right of judging them, in all cases of offences committed in the exercise of their functions. There are six ministers, viz., a minister of foreign affairs, of the interior, of justice, of finance, of war, and of public works.

Divisions. For civil purposes the provinces are divided into 26 arrondissements, 203 justice-of-peace cantons, and 2528 communes; and for military purposes, into 4 arrondissements, 268 military cantons, and 2198 communes. The following table gives the civil divisions of each province:—

Provinces.	Arrondissements.	Cantons.	Communes.
Antwerp, ...	Antwerp,	7	57
	Malines,	6	39
	Turnhout,	6	50
Brabant.....	Brussels,	10	120
	Louvain,	7	111
	Nivelles,	5	107
West Flanders	Bruges,	10	77
	Courtray,	11	67
	Turnes,	4	58
	Ypres,	7	47
East Flanders	Oudenarde,	8	113
	Ghent,	14	105
	Termonde,	10	75
Hainault	Charleroy,	9	147
	Mons,	9	140
	Tournay,	11	140
Liège.....	Huy,	7	131
	Liège,	8	144
	Verviers,	6	56
Limbourg	Hasselt,	6	76
	Tongres,	7	127
Luxembourg.....	Arlon,	6	60
	Marche,	7	67
	Neufchateau,	7	68
Namur	Dinaut,	9	222
	Namur,	6	124
	Total	303	2528

In each province is a governor named directly by the king for the purpose of superintending and securing the due execution of the laws, and a provincial council, the members of which are chosen directly by electors having the same qualifications as the electors to the legislative chambers.

Provincial councils. The councils are composed of Belgic citizens at least twenty-five years of age, residing in the province, and in the enjoyment of civil and political rights. Members of the chambers, governors, and persons in the employment of the state or province, are excepted. They have an annual session of not more than four weeks; but the king can convoke them on extraordinary occasions. Those not residing in the provincial capital receive an indemnity during the session.

In 1836 the number of councillors for each province was fixed according to the population, as follows: for the provinces of Brabant, West Flanders, East Flanders, and Hainault, one to each 10,000 inhabitants; for Antwerp, Liège, Limbourg, and Luxembourg, one to each 7500; and for the province of Namur one to each 5000 inhabitants. It was, however, agreed that every canton should have at least one councillor, whatever might be its population, and that the same scale should be applicable to it as to the province in which it was situated. The treaty of 1839 having reduced Luxembourg and Limbourg, the proportion for these was fixed at one to each 5000. The number of councillors in 1850 was 461, as follows: Antwerp 46, Brabant 57, West Flanders 64, East Flanders 73, Hainault 61, Liège 50, Limbourg 33, Luxembourg 34, and Namur 43. The number of electors in each electoral section cannot exceed 600 nor be below 200. The number of ordinary electors was 78,228, and of supplementary 5003.

Belgium.

These councils are of the highest importance to the country. They watch over the interests of their various provinces, prepare the budgets, direct the taxation, and superintend public works. They give a healthy impulse to agriculture, trade, and commerce; direct the construction of roads, canals, and bridges; and extend the benefits of education and religion throughout the country. The communes have the power of appeal to the king if they consider themselves aggrieved by any of the acts of the provincial council, or of the permanent deputation. In the ten years preceding 1851 only two appeals had been made against the provincial council, and thirty against the permanent deputation; and in only two of these had the decisions been altered.

Permanent deputation. Each provincial council appoints a permanent deputation for conducting business in the interval between the sessions, particularly in matters requiring immediate attention. It is composed of six members chosen for four years, one-half going out every two years.

Communal councils. Matters exclusively communal are managed by communal councils. The councillors are Belgic citizens in the full enjoyment of civil and political rights, and, except in some special cases, resident in the commune. They are elected for six years, one-half going out every three years. The number of the councillors varies from 7 to 31, in proportion to the population of the commune, varying from under 1000 to upwards of 70,000 inhabitants. All citizens paying taxes varying from 15 francs (nearly 12s.) to 42 francs 32 cents (L.1, 13s. 6d.), according to the population, have a vote in the election of communal councillors. Of the 4,338,447 inhabitants in 1848, 194,413 were electors, and 20,849 councillors were elected, of whom $\frac{7}{10}$ths had been previously elected. Communes with less than 20,000 inhabitants have two aldermen, and those having more than that number have four. There is also in each commune a burgomaster, who, as well as the aldermen, is chosen by the king from among the members of the communal council.

Judicial system. The judicial system of Belgium consists of courts and tribunals of various kinds, as the court of cassation, the courts of appeal, of assize, tribunals of primary instance, of commerce, &c.

For all criminal and political cases, as well as offences of the press, trial by jury is established. The jury is composed of twelve persons chosen by lot from a leet of thirty, partly by the public minister and partly by the accused.

Justices of the peace and judges of the tribunals are chosen directly by the king. The councillors of each court of appeal, and the presidents and vice-presidents of the tribunals of primary instance in its district, are chosen by the king from two double lists of candidates, the one presented by the court of appeal, and the other by the provincial council. The councillors of the court of cassation are named by the king from two double lists, the one presented by the senate, and the other by the court of cassation. The judges are appointed for life, and cannot be suspended or deposed but by a judgment. They cannot hold any salaried office under the government, or at least must perform the duties of it gratuitously. The duties of public minister at the court

Belgium.

of cassation are exercised by a procurator-general and two advocates-general; and by a royal procurator with substitutes before each of the tribunals of primary instance and courts of assize and appeal.

Court of Cassation.

The Court of Cassation or annulment sits at Brussels, and is divided into two chambers, the one for civil and the other for criminal matters. It is composed of a president-general, a president of each chamber, and fifteen councillors. It decides upon appeals against judgments pronounced in the other courts and tribunals in contravention of legal forms.

Appeal courts.

There are three courts of appeal: one at Brussels, for the provinces of Antwerp, Brabant, and Hainault; another at Ghent, for the two Flanders; and a third at Liège, for Liège, Limbourg, Luxembourg, and Namur. These decide upon appeals from the decisions of the tribunals of primary instance in civil matters, and affairs of commerce and correctional police.

Courts of assize.

In the capital of each province is a court of assize, composed of a councillor deputed from one of the courts of appeal, who presides, and of two judges chosen from among the presidents and judges of the primary tribunal where the court is held. Crimes, graver misdemeanours, political offences, and abuses of the press, are judged by the courts of assize.

Primary tribunals.

In each judiciary arrondissement is a tribunal of primary instance, judging in misdemeanours belonging to the correctional police, in civil matters, and in commercial affairs where there is no commercial tribunal, but in cases above 2000 francs (L.79) its decision may be brought before the courts of appeal. The number of judges varies from three to ten in each tribunal, amounting in all to 148.

Tribunals of commerce.

Tribunals of commerce are established by law in several principal towns. They judge definitively in civil matters of not more than 2000 francs, but above that sum their decisions are subject to appeal, as in the tribunals of primary instance. Each is composed of a president, from two to eight judges, and substitutes. The members of the tribunal are chosen by the leading commercial men, amounting in 1850 to 1759. There are thirteen tribunals of commerce, established in the towns of Antwerp, Brussels, Louvain, Mons, Tournay, Bruges, Ostend, Courtray, Ghent, St Nicolas, Liège, Verniers, and Namur.

Councils of prud' hommes.

In several of the manufacturing towns are councils of *prud'hommes*, composed of master tradesmen and workmen chosen for three years, a part going out annually. The number of members varies from five to nine in each council, except in that of Brussels, which has fifteen members. They decide in all questions and disputes arising between masters and workmen. A special board of two members first attempts to effect a reconciliation between the parties, and if unsuccessful the matter is then brought before the council for decision. Previous to 1843 there were only two of these councils, one at Ghent and the other at Bruges. Since then government has been authorized to establish twenty additional ones, and of these thirteen are now in operation.

Justice of peace.

In each canton is a justice of the peace, with a registrar and two substitutes. These constitute tribunals of simple police for the trial of offences involving a fine of not more than 200 francs (nearly L.8), or imprisonment for not more than eight days. The commissary of police performs the duties of public minister.

Councils of war.

Councils of war are held in the chief place of each province, with the exception of Limbourg, which is joined to Liège, and of Luxembourg, which is united with Namur. They decide in crimes and misdemeanours committed in their provinces by the military of a rank not higher than captain. They are composed of seven members, including the president, who ought all to be of the grade of officers.

Military court.

The military court for the whole of Belgium has its seat at Brussels. It is composed of five members, one of whom is a councillor of the appeal court of Brussels, delegated annually to preside; the rest are general or superior officers chosen by lot every month. It decides on appeals from the courts of war. All officers of a grade superior to that of captain are amenable to this court.

Belgium.

Police.

Besides the several bodies of ordinary police, there are commissaries of police, royal procurators, *juges d'instruction*, &c. The commissaries of police, and, in the communes where these are wanting, the burgomasters or delegated aldermen, are specially charged with searching out and proving all contraventions of the police laws. The royal procurators are charged with discovering and prosecuting for all offences coming within the jurisdiction of the courts of assize or the correctional tribunals of police. There is at least one *juge d'instruction* or examining judge in each arrondissement (in Brussels there are three). They are chosen by the king from among the judges of the tribunal, and continue in office for three years. They are specially charged with the collection of evidence, and with bringing the culprit before the tribunal. There is a council-chamber composed of at least three judges, including the *juge d'instruction*, for the preliminary examination of culprits.

Prisons.

The prisons are of three classes:—1. Houses of municipal police; 2. Houses of arrest and justice; and, 3. Central houses of punishment. Of the first class there are 168, containing, in 1850, 10,373 prisoners. In the capital of each province the seat of a court of assize is a house of justice; and in the capital of each arrondissement the seat of a court of primary instance is a house of arrest. In connection with many of these, schools, workshops, and circulating libraries have been established. There are eight central houses of punishment:—1. At Ghent, for compulsory labour; 2. At Vilvorde, for seclusion; 3. At St Bernard (near Antwerp), for correctional imprisonment: 4. Military house of detention at Alost; 5. Female penitentiary at Namur, for those condemned to imprisonment, seclusion, or compulsory labour; 6. Penitentiary of St Hubert (Luxembourg), for young male delinquents condemned to at least six months' imprisonment, and for children acquitted as having acted without discernment; 7. A penitentiary at Liège for young females, similar to the preceding; 8. The citadel of Huy, for persons convicted of political offences. Each prison is under the direction of a committee of management, whose services are gratuitous. The superior board of control has the general superintendence of the prisons, and an inspector-general and two comptrollers are charged with their inspection and direction. In each central prison are schools, at which attendance is obligatory on all prisoners under forty, and optional for those above that age. The number attending these schools in 1850 was 3578, or about 68 per cent. of the prisoners.

The prisoners are employed in various kinds of work. Those condemned to compulsory labour receive no remuneration, but those condemned to seclusion or correctional imprisonment receive a part of the produce of their labour, and which, in the case of the latter is frequently applied in mitigation of their punishment. Premiums are also given for good conduct, zeal, and progress in their labours. The total expense of the prison establishments for 1849 was 4,133,703 francs.

Population.

The population of Belgium in 1831 was 3,785,814; in 1840, 4,073,162; and in 1850, 4,426,202; distributed as follows:—

	1831.	1840.	1850.
Antwerp	349,942	371,157	420,556
Brabant	561,828	621,072	734,617
West Flanders	608,226	646,054	631,137
East Flanders	742,973	779,466	783,450
Hainault	613,179	661,701	733,740
Liège	375,030	410,171	467,843
Limbourg	160,090	169,960	188,198
Luxembourg	160,762	174,719	192,588
Namur	213,784	238,862	274,073
	3,785,814	4,073,162	4,426,202

Belgium.

The increase for the first period was 7·60 per cent., and for the second 8·67 per cent. At the date of the general census in 1846 Belgium contained 86 towns, 2436 rural communes, and 4,337,196 inhabitants. The first-class towns were—Brussels, 123,874 inhabitants; Ghent, 102,977; Antwerp, 88,487; Liège, 75,961. The second-class were—Bruges, 49,308; Louvain, 30,278; Tournay, 30,125; Malines, 29,693. Those having from 20,000 to 25,000 inhabitants were Mons, Verviers, Namur, Courtray, and St Nicolas; from 15,000 to 20,000, Alost, Ypres, and Lokeren; and from 10,000 to 15,000, Turnhout, Ostend, Lierre, Renaix, Thielt, St Troud, Roulers, Poperinge, and Tirlemont.

According to that census the density of the population averaged 147·24 inhabitants per 100 hectares, or 247 acres. The density, however, varied considerably in the different provinces, as will be seen from the following table:—

	Population.	Extent in Hectares.	Proportion of the Average to the Kingdom.
East Flanders	793,264	299,787	1·797
Brabant	691,357	328,323	1·457
West Flanders	643,004	323,448	1·350
Hainault	714,708	372,205	1·304
Liège	452,828	289,319	1·063
Antwerp	406,354	283,311	0·974
Limbourg	185,913	241,315	0·523
Namur	263,503	366,181	0·489
Luxembourg	186,265	441,704	0·287

The proportion falls below the general average in the provinces of Antwerp, Limbourg, Namur, and Luxembourg, and exceeds it in the other five.

The number of dwelling-houses was 799,848; of which 625,498 were of one story, 146,464 of two stories, and 127,886 of three or more stories; 160,471 were insured, the amount of capital insured being 1,093,030,336 francs. The number of families was 890,566; of which 154,454 inhabited only one apartment, 282,785 two apartments, and 453,327 three or more apartments. The number of married persons in 1846 was 1,322,588; of unmarried, 2,771,975; and of widows, widowers, and divorced, 242,633;—4,242,380 were born in Belgium, 34,600 in France, 12,859 in Germany, 3828 in England, 38,910 in Holland (including Dutch Luxembourg and Limbourg), and 4624 in other countries.

Languages.

The principal languages spoken in Belgium are French, or Walloon (a dialect of the ancient French), and Flemish or Dutch. French is the language of the upper and educated classes, and is generally understood even in the Flemish parts of the kingdom. In 1846 those speaking French or Walloon amounted to 1,827,141; Flemish or Dutch, 2,471,248; German, 34,060; English, 3824; other languages, 923. The French or Walloon is the prevailing language in the provinces of Hainault, Liège, Luxembourg, and Namur; the Flemish or Dutch in Antwerp, Brabant, the two Flanders, and Limbourg.

Registers.

Registers of the movement of the population in each commune are kept by the burgomaster or an alderman. The commissioners of the arrondissement inspect annually the various communal registers within their districts, and give notice of any irregularities or inaccuracies, to the permanent deputation of the provincial council; and the royal procurators are specially intrusted with the verification of the acts and registers. These contain the name, age, profession, and place of birth, of each inhabitant of the commune. The births, deaths, and other changes among families, as well as the names of those who enter or leave the commune, are daily registered. A new entry can be made only on the production of a certificate from the administration of the last domicile, or, in the case of a foreigner, on the production of his passport. Each commune is bound to remit monthly to the governor of the province a list of all persons who have settled in or left the commune during the month. The provincial registers are annually sent to the central committee of statistics. Since 1851 valuable improvements have been introduced, so that the register of deaths now indicates not only the age, sex, profession, &c., of the deceased, but also the disease or accident that occasioned death, whether medical treatment had been received, &c.

Belgium.

Since 1840 the bureau of general statistics has annually published a report of the movement of the population, made up from the yearly communal reports. The total number of births during the ten years preceding 1851 was 1,299,681, the annual average being 129,968; of which 66,648 males and 63,320 females. The annual average of legitimate births during that period was 120,303. In 1850 the number is somewhat, and in 1846–7–8 considerably, below the average; and in the other years exceeds it. The illegitimate births during that period were 96,652, averaging one for every 12·45 legitimate births. In the province of Luxembourg they are only one in 38·52; and in that of Brabant one in 6·83. In comparing the results of these years, the proportion of illegitimate births to legitimate has been annually increasing from 7·16 per cent. in 1841, to 9·11 in 1849, and 9·42 in 1850. The proportion of male to female births is 102·5 males to 100 females. The greatest number of births is in the months of February and March, and in the six months from November to April; the least in July and August. The still-born are as one to every 23·87 births; of males one in 21, and of females one in 27.

Births.

The deaths in that decennial period were 1,040,497; of these 314,313 were unmarried males, and 304,465 unmarried females; 136,492 married males, and 119,555 married females; 66,205 widowers, and 99,467 widows. The year 1849 presents the greatest number of deaths in this period, arising from the cholera, which alone carried off 23,027 victims. In the years 1846–7–8, the deaths are also considerable, from epidemic diseases which were then prevalent in the country; in 1847, indeed, the deaths were to the births as 101·75 to 100, while in the years 1841–44–50, the births exceeded the deaths by 30 per cent. The average number of deaths to 100 births during the ten years was 80. In the provinces of West and East Flanders the deaths are above the average, being in the former 97·6, and in the latter 91·5; the others are below the average, except Limbourg, which is equal to it, Namur, the lowest, being 60·7. The great mortality in the Flanders is ascribed to the greater prevalence there of the above-mentioned epidemics; the excess of deaths was 26·626 over the 100 births. The greatest number of deaths are in the half-year from November to April, mostly in January, February, March, and April; the least in August, September, October, and November. Of the deaths during this period, 6·46 per cent. were not more than one month old, 18·77 not exceeding one year, 26·16 not more than two years, and 48·98 not exceeding 25. Between 25 and 50 the deaths were only 16·83 per cent.; from 50 to 60 only 7·53; from 60 to 70, 10·10; from 70 to 80, 10·68; from 80 to 90, 5·23; and from 90 upwards, 0·65. To the end of the second year, the deaths in males exceed those in females as 18·52 to 15; from that age to 45, the females exceed the males as 17·27 to 15; from 45 to 55, the males exceed the females as 2·14 to 2; and from 55 upwards, the females exceed the males as 12·08 to 10. The number of suicides in the ten years was 2428.

Deaths.

The proportion of marriages to legitimate births is one to 4·15. The number of marriages during the above decennial period was 289,676.

Marriages.

Naturalization is of two kinds, the one conferring on the foreigner all the civil and political rights belonging to a Belgian, with certain exceptions specified by law, such as eligibility for a seat in the legislative chambers: to obtain these the *grand naturalization* is requisite. The registration fee for the former is 500 francs; for the latter, 1000.

Naturalization.

In order to arrive at a somewhat correct notion of the

Crime.

Belgium. state of crime in the country, we shall take the annual average of the number of persons brought before the various courts of assize for several periods. For the five years preceding 1831, the annual average of persons accused was 766; being 200 crimes against person, and 566 against property. From 1831 to 1839 the average was 577; being 184 against person, and 393 against property; showing, notwithstanding the increase of the population, a considerable decrease in the amount of crime. From 1839 to 1845 the average was 438; being 117 against person, and 321 against property. The decrease in this case is more apparent than real, arising principally from the lighter offences being remitted to the tribunals of correction; as also from the annexation of part of the provinces of Limbourg and Luxembourg to Holland, in terms of the treaty of 1839. In the next three years there was a deficiency of the crops and of employment, occasioning a state of distress such as had not been known for a long time previously in the kingdom. Under these circumstances the offences against property considerably increased. The average during that period was 575, being 101 against person, and 474 against property. Happily this increase of crime ceased with the producing cause, so that the number of accused in 1849 little exceeds the average of the period preceding that crisis, being 451, —113 against person, and 338 against property. Of these, 104 were acquitted, 41 condemned to death, and 34 to compulsory labour for life.

For the ten years preceding 1850 the number accused of crimes was 4570; of these 1332 were acquitted, 311 condemned to death, 377 to compulsory labour for life, 904 to compulsory labour for a period, 1068 to seclusion, and the rest to correctional punishments. The propriety of capital punishments is here a much contested point, and the royal clemency is exerted in all except the most aggravated cases. Of the 311 persons capitally condemned, only 23 were executed. Of the 4570 accused, 3802 were males and 768 females; 1343 were under 25 years of age, 1970 between 25 and 40, and 1249 of 40 and upwards: 64 per cent. had received no education, and only 3 per cent. any education beyond mere reading and writing. Comparing the number of the accused with the population, after deducting children under 10 years of age, we find the proportion among males to be one in 4272, and among females one in 21,430.

In 1849 the accused before the correctional tribunals amounted to 32,509; of these 17,383 were misdemeanours, 1107 minor crimes, and 14,019 contraventions of police or special laws;—5018 were acquitted, 15,336 sentenced to imprisonment, and 12,148 fined: 2096 had been previously convicted. The number brought before the tribunals of police was 38,081; of these 4489 were acquitted, 257 remitted to a higher tribunal, 25,818 fined, and 7517 imprisoned.

A criminal appearing a second time before a court is condemned to the punishment immediately above that fixed by law for his crime; and if guilty of a misdemeanour punishable correctionally, he is condemned to the maximum punishment allowed by law for that offence. The number of those brought before the courts of assize for the ten years preceding 1850, and who had been previously condemned, was 1434, or about 31 per cent. of the accused for that period.

Religion. Full liberty is guaranteed to all in the exercise of the public or private rites of their worship; nor does the state interfere in any way in matters of religion, except where the public safety may be concerned or the laws infringed. The population of Belgium in 1846 was 4,337,196; of these 4,326,873 were Roman Catholics, 6578 Protestants, 1336 Jews, and 790 belonged to the Anglican Church. The incomes of the ministers of each of these sects are derived from the public treasury. The amount thus paid by the state in 1850 was, to the Catholics, 3,628,130 francs (L.143,636), to the Protestants, 45,099 francs (L.1785), to the Jews, 9500 francs (L.376), and to the Anglicans, 10,300 francs (L.407). Belgium

Catholic. The Roman Catholic religion embraces upwards of 99 per cent. of the entire population. The kingdom is divided into six dioceses, the archbishopric of Malines, and the bishoprics of Bruges, Ghent, Liège, Namur, and Tournay. The archbishopric has three vicars-general, and a chapter of twelve canons; and each of the bishoprics, two vicars-general, and a chapter of eight canons. In each diocese is an ecclesiastical seminary. There was formerly one rectory in each justice of peace canton, but the number of the latter having been reduced, the rectories now outnumber the cantons by 25, and amount in all to 229, being 86 of the first class and 143 of the second. Chapels of ease are established throughout the country where necessary: these amounted in 1851 to 2640. The number of public chapels established as secondary chapels of ease, &c., at first unendowed, but of which the chaplains are now placed on the same footing as vicars, was 148, and of vicariates 1555. The salaries of each of the several kinds of ecclesiastics are as follows:— Of the archbishop, 21,000 francs (L.831); of the bishops, 14,700 francs (L.582); vicars-general of the archbishop, 3600 francs (L.142), of the bishops, 3200 francs (L.126); canons of the archbishop, 2400 francs (L.95), of the bishops, 2000 francs (L.79), rectors of the first class, 2047 francs (L.81), of the second class, 1365 francs (L.54); officiates in the chapels of ease, 787 francs (L.31); chaplains and vicars, 500 francs (L.20). These incomes, however, may be augmented by the church or communes. The amount contributed for that purpose by the communes in 1849 was 520,845 francs (L.20,617). This, however, includes the sum given by the urban communes to the support of the ecclesiastical edifices; the sum given by the rural communes for that purpose is mentioned afterwards. These do not include the chaplains of prisons nor of the army. Those of the army are divided into three classes, the first receiving a salary of from 2000 to 3000 francs, the second from 800 to 1000 francs, and the third from 400 to 600 francs.

The temporal affairs of the churches are managed by a vestry-board composed of a council, and a board of wardens. In parishes having 5000 inhabitants and upwards, the council is composed of nine members, and in other cases of five. It is renewed every six years, a part going out every three years. The new members are chosen by the remaining councillors. The ecclesiastical officiate in the church and the burgomaster of the commune are entitled to a seat. The council holds four ordinary assemblies annually. The board of wardens is composed of three members of the council and the officiating clergyman. One of the members goes out annually. This board acts under the council, and meets once a month.

The total number of students attending the diocesan seminaries in 1846 was 740. Scholarships of 423 francs (L.16, 14s.), and half scholarships of 211 francs (L.8, 7s.), are annually given by the state to certain of the students upon the presentation of the chief of the diocese. There are 66 of these scholarships, and 217 half scholarships. The state also contributes to the salaries of the professors by an annual grant of 8000 francs (L.317) to each of the seminaries, except that of Liège, the grant to which has been withdrawn since 1849, as it has sufficient funds otherwise. The provinces are bound to provide and maintain suitable buildings for these seminaries.

The amount contributed to the support of religious edifices by the provinces in 1849 was 253,193 francs (L.10,022), and by the rural communes, 155,252 francs (L.6145). Numerous donations and legacies have been given by private individuals for ecclesiastical purposes, amounting, for the twenty years preceding 1851, to 6066, and comprehending houses, lands, money, &c. The acceptance of these, if above 3000 francs in value, requires to be sanctioned by the

Belgium. government, and by the permanent council if not exceeding that sum. The total value of these, including two of the value of 100,000 francs (L.3958) to the Protestant church, was 16,306,481 francs (L.645,465).

There are a number of religious houses in Belgium for males and females whose lives are spent in pious contemplation, teaching, and visiting the sick. The number of these houses in 1846 was, for males, 137, and for females, 642; the number of persons in the former was 2051, and 9917 in the latter.

Protestant. The Protestant-evangelical church is under a synod composed of the clergymen of the body, and a representative from each of the churches. It sits in Brussels once a-year, when each member is required to be present, or to delegate his powers to another member. Included in the sum of L.1785 already mentioned as given by the state to Protestant pastors, are certain sums granted to the families of such clergymen. Each child is allowed the sum of 25 florins (L.2) till attaining the age of twenty-one years. A bursary of 25 florins is given to each child attending a Latin school, or receiving private lessons in that language; one of 50 florins to each attending a university or athenæum; and one of 200 florins to each studying theology. In 1850 twenty-three children were receiving the first-mentioned allowance, one a school, and one an academy bursary.

Anglican. The Anglican church has six pastors and as many chapels, in Belgium,—two in Brussels and one in each of the towns of Antwerp, Bruges, Ostend, and Spa.

Jewish. The Jews have a central synagogue at Brussels, three branch synagogues of the first class at Antwerp, Ghent, and Liège, and one of the second class at Arlon. The civil and religious affairs are conducted by a consistory of nine members, six of whom are appointed by the central, and one by each of the three first-class synagogues. The grand Rabbi, who is at the head of this body in Belgium, is *ex officio* a member of the consistory. They meet once a month, and two of the members go out annually.

Education. The Belgian government has shown itself thoroughly alive to the great importance of a general diffusion of education among the people. Numerous public schools and literary and scientific institutions are established throughout the country, supported out of the communal, provincial, or government funds. Different classes of inspectors are appointed to visit and report upon the state of education in their various districts. Prizes, scholarships, and other rewards are bestowed upon those that distinguish themselves most in the prosecution of their studies. Religious and moral instruction is under the direction of the sect to which the majority of the pupils belong; but those connected with other sects may be exempted from attendance on this course. Normal schools have also been established for the purpose of securing trained and efficient teachers. Meetings of the teachers and inspectors are frequently held for conversing upon the various methods of teaching, and other matters connected with education. *Caisses de prevoyance* are also established to afford aid to aged or infirm teachers, and their widows and families. The schools are open to all, and gratuitous instruction is provided for those who may not otherwise have the means of acquiring it. Yet, with all these advantages, it cannot be denied that there are still many among the lower classes growing up in ignorance and crime. Indeed, it seems undeniable that the providing of the means of instruction is not alone sufficient to secure an educated population. In the industrial localities the parents are generally anxious to get their children admitted as soon as possible into workshops and manufactories, and in rural districts they are engaged in the tending of cattle or in field labour. In some localities efforts have been made to counteract this evil,—the people have been addressed from the pulpit on the advantages of education; the parents have been conversed with upon the same subject, and, in some cases, the participation in public charities has been made subservient to sending their children to school. Some idea of the state of education in the country may be gathered from the annual draughts for the militia. In 1850 the number drawn was 38,328: of 21 of these the state of education was unknown; 13,965 had received no education; 2945 could read only; 9295 could only read and write, and 12,102 had received a more advanced education. Contrasting the period from 1843 to 1847, with the years 1849 and 1850, we find that in the former 41 per cent. were without instruction, 8 could read only, 27 could read and write only, and 24 were more advanced. In the latter period there is a considerable improvement; 38 per cent. were without instruction, 7 could read only, 25 could read and write only, and 30 were more advanced. In entering rather fully into the state of education in this country, we do so both from the great importance of the subject in itself, and from a conviction of the beneficial results that must eventually follow from it.

Belgium.

The educational institutions may be divided into four classes, viz., primary, middle, superior, and special. In 1846, the number of children receiving primary instruction at the schools was 441,172, and at home 5632; the number of those receiving middle or superior instruction at the athenæums, colleges, universities, &c., was 24,636, and at home 1050, showing a total of 472,490 receiving instruction at that period, or one in every 9·18 of the population. Since that time the number has been much increased.

Schools.

The primary schools are under the surveillance of the communal authorities and government inspectors; the imparting of moral and religious instruction is superintended by delegates from the religious bodies. Each province has a general inspector of the primary schools, who is appointed by the king, and inspects at least once a-year all the communal schools in his district, on which he makes an annual report. Under him are the cantonal inspectors, who are bound to visit the schools in their districts at least twice a-year. They are appointed by the state on the advice of the provincial government, and continue in office for three years. The provincial inspectors assemble annually in a central commission under the presidency of the minister of the interior. The bishops and consistories of the religions supported by the state may be represented by delegates at this commission, but these have only a deliberative voice in the proceedings. Ministers of religion and delegates of church dignitaries have the right of, at any time, inspecting the primary schools. The diocesans and consistories annually communicate to the minister of the interior a detailed account of the state of moral and religious instruction in the schools under their care. For the schools connected with the Roman Catholic communion there are two classes of inspectors; the diocesan inspectors, of whom there is one for each province, and the ecclesiastical cantonal inspectors. The Protestant schools are inspected by a delegate of the consistories, having the title of inspector-general. The Jewish schools have also an inspector-general delegated by the consistory.

Primary schools; inspectors.

The cantonal inspector calls a meeting of the teachers in his district at least once every three months, to discuss the merits of the different modes of teaching employed, the state of primary education, and the best means of advancing it. Educational libraries have recently been formed in connection with each of these districts.

A law passed in 1842 enacted that there should be at least one primary school in every commune, except in certain cases where primary education is already sufficiently provided for by private schools, or where one school may serve for several neighbouring communes. The communes may also adopt one or more private schools possessing the legal qualifications, to occupy the place of the communal school. The total number of primary schools, public and private, in the end of 1848, was 5747, of which 1008 were exclusively for boys, 1202 exclusively for girls, and 3537 for both sexes. Of these 2626 were communal schools, 913 private adopted schools, 58 private schools under inspection, and 294 boarding schools. The scholars receiving primary instruction at that time were 462,606, and in the end of 1849 were 493,773; being an increase of more than 200,000 since the end of 1830; and in the proportion of 11·2 per cent. of the population.

The branches taught in the primary schools are reading, writing, and the elements of arithmetic; the rudiments of the language spoken in the locality,—French, Flemish or German; moral and religious instruction; and the legal system of weights and measures, in most schools taught practically. In many of the schools gymnastics, music, and the elements of drawing, the outlines of history and geography, and the rudiments of the natural sciences, are also taught. Competitions take place annually, under the direction of the permanent deputation, between the scholars in the superior division of a certain number of the primary schools. The number of scholars from each school is fixed by the deputation, one-half chosen by the teacher and the other half by lot. The jury of examiners is presided over by the inspector of the district or his substitute.

The communes are obliged to afford gratuitous instruction to all the children within their bounds whose parents are in poor circumstances, and may not otherwise have the means of educating them. For that purpose there is a register in each province, open annually during the month of July, to receive the names of all the children claiming gratuitous instruction for the next scholastic year, which extends from the beginning of October to the end of August. This register is submitted to the communal council, which decides what children are entitled to gratuitous instruction, and this decision is then communicated to the permanent deputation of the provincial council. Claimants for gratuitous instruction are required to be between seven and fourteen years of age, and to have been vaccinated, or had the smallpox. The number of children receiving gratuitous instruction at the end of 1848 was 219,731.

Schoolmasters.

The schoolmaster is appointed by the communal council, which has also the power of suspending him for a period not exceeding three months,—the government decrees as to his reinstatement or dismissal. He ought to have attended, for at least two years, the classes of a normal school. This condition may, however, be dispensed with, if assented to by the government. In the case of a vacancy, the communal council is bound to fill it up within forty days, except in cases where the government may sanction a longer delay. On the expiration of that period, the nomination is proceeded with by the government. The male and female teachers in the communal schools in 1848 were 2786, besides 296 assistants.

Income.

The minimum salary of a teacher, as fixed by law, is 200 francs, or nearly L.8. Besides this, they have generally an allowance for the gratuitous instruction of poor children, a free house with, particularly in the rural districts, a garden, and in many cases the school fees. The fees vary considerably, according to the locality and other circumstances; they are in all cases fixed by the communal council. The average income of the teachers exceeds 600 francs. Some teachers considerably augment their incomes by the performance of other duties unconnected with their office, as those of communal secretary, &c. Rewards are bestowed on those who distinguish themselves most in the performance of their duties. These are of three kinds,—a gratuity of 50 francs, *a gift*, and *honourable mention*.

Caisses de prevoyance.

In each province is a *caisse de prevoyance* for the purpose of affording pecuniary aid to aged and infirm teachers, their widows, and children. All teachers and assistants in the communal primary schools are obliged to become members of this institution. The widow of a teacher who has been engaged for twelve years is entitled to a pension, and also the children of such teacher till the completion of their sixteenth year. These *caisses* are under the direction of the governor of the province, the members of the permanent deputation of the provincial council, provincial treasurer, and the provincial inspector of primary schools, whose services are gratuitous. They are supported by an annual payment of three per cent. upon the income of each member, by grants from the province and the state, and by particular donations and legacies. Besides these primary schools properly so called, there are in many localities other establishments where primary instruction is communicated, as the infant, adult, manufacturing schools, &c.

Infant schools.

The infant schools are for children between two and six years of age. There were 516 of these in 1848, 204 being communal or adopted, and 312 private. The scholars amounted to 28,593, of whom 13,183 were males, 15,410 females; of these 16,926 were admitted gratuitously. Some of these institutions are reported as being in a high state of efficiency, but in most of them there is much room for improvement, arising from the want of funds, and from the teachers in many cases possessing neither the knowledge nor the talents necessary for their duties. The expense of those schools for 1846, 1847, and 1848, was 243.927 francs (L.9655), of which 65,636 francs were derived from charities, 96,109 from the communes, 10,530 from the provinces, 38,787 from the state, and 32,865 from the fees.

Adult schools.

The adult schools in 1848 amounted to 1110, of which 41 were day schools, 336 evening schools, and 733 Sunday schools; 442 were under inspection. The number of scholars was 184,348, of whom 111,213 were receiving gratuitous instruction. The branches taught in these are generally the same with those in the communal primary schools. The inspected adult schools are supported in the same way as the infant schools, the expenses for 1848 being 44,582 francs (L.1765).

There are primary schools annexed to prisons, hospitals, and depôts of mendicants; and reform schools. The scholars attending these at 31st December 1848 amounted to 6086. The manufacturing schools in their present state can scarcely be viewed as educational institutions. Although the means of education are provided, little time is devoted to that object, being almost entirely taken up in manual labour.

Considerable sums are given by government for providing food, clothing, and other necessaries to the poor children attending the primary and infant schools;—for the four years preceding 1849 these amounted to 72,400 francs (L.2850).

Expense of education.

The expenses of public primary education fall in the first instance on the commune; and in case of insufficiency of funds, the province, and finally the state, come to its assistance. Each commune, however, must contribute a sum at least equal to two per cent. upon its direct taxation before being entitled to claim any assistance from the province or state. The total expenditure for public primary education was, in 1846, 3,837,197 francs; in 1847, 4,137,220; and in 1848, 4,376,675 francs, or L.173,243. Of this last 304,500 francs were public or private donations; 783,830 school fees; 1,586,918 contributed by the communes; 512,370 by the provinces; and 1,189,057 by the state. The expenditure for that year was as follows:—

	Francs.
The central commission and provincial inspection...	101,420
Cantonal inspection	78,181
Conferences of the teachers	15,737
Ordinary expenses of instruction.....	2,756,892
Construction and repairing of school-houses	614,097
Grants to *caisses de prevoyance* scholarships, &c.	156,790
Infant, adult, and manufacturing schools, &c.	349,817
Normal and superior primary schools.....	303,741
	4,376,675

The last item of this list does not properly belong to what are now considered as primary schools, the normal schools being placed among the special schools, and the superior primary schools having since that time been classed with the middle schools. Comparing the amount expended in primary education with the population, we find that in 1846 it was 0·884 francs for each inhabitant, in 1847 it was 0·953, and in 1848, 1·005.

Middle schools.

The middle schools are divided into two classes, those supported by the government, and those maintained by the province or commune. The former are of two kinds, the royal athenæums, called also the middle superior schools, and the middle inferior schools, or the middle schools properly so called, including the former superior primary as well as the government industrial and commercial schools.

The superior primary schools have only very recently been classed among the middle schools, and are included in the general statistics of primary education, already given as at that time belonging to that branch. These schools, 22 in number, were established in the principal towns, and in 1849 had 2978 pupils. The branches taught included land-measuring and other branches of practical geometry, the rudiments of the natural sciences, the elements of history and geography, drawing, music, and gymnastics, with in some cases the German and English languages, and book-keeping. The educational staff consisted of a rector, with one or more teachers and assistants; the first nominated by the king, and the last two by the minister of the interior.

The government has the general management of the state middle schools, in which it is assisted by a local board of administration for each school, composed of the burgomaster and

aldermen, and of from four to six members nominated by the government from a list of candidates presented for that purpose by the communal council, with a secretary. The services of the board are gratuitous;—an election takes places every three years, but the same members may be re-elected. They have the general direction of the institution, the preparation of the budgets, making up the annual reports, and presiding at the distribution of the prizes, &c. Members of the board may at any time visit and examine the classes.

Inspection. These, like the primary schools, are also subjected to a regular system of inspection. The literary and scientific branches are under the superintendence of two inspectors and an inspector-general, nominated by the king. To one of the inspectors is especially confided the mathematical and natural sciences, and to the other the humanities; the other branches, as history, geography, and the commercial sciences, may be committed to either of the inspectors or to the inspector-general. Once a-year, at least, each of the athenæums are visited by the inspector-general and both the other inspectors, and the other establishments by one of them. The time and duration of each tour of inspection is fixed by the minister of the interior, who also gives special instructions concerning it, on the advice of the *conseil de prefectionnement*. The inspector has to examine and report upon the state and discipline of each establishment, the methods employed in teaching, the progress made by the pupils, and the merit and zeal of the teachers. These reports are annually sent by the inspector-general to the minister.

Conseil de prefectionnement. The *conseil de prefectionnement* of middle instruction is composed of from eight to ten members, presided over by the minister of the interior or his deputy, and meets at least four times a-year. It advises upon the programmes of the studies, examines the books used in teaching or given as prizes, proposes directions to be given to the inspectors and examines their reports, and deliberates on subjects connected with the advancement of middle instruction.

Competition. A general competition takes place annually between the scholars of the athenæums and colleges receiving grants from government; in which, however, scholars from other establishments may be admitted to take a part on a request being presented to the minister of the interior to that effect. They are examined by a jury, nominated by the minister of the interior, and divided into two sections, the one for the humanities and the other for the mathematical sciences. The examinations are both written and oral; and the rewards are of three kinds, prizes, *accessits*, and honourable mention.

Educational staff. The educational staff consists of a prefect of studies in the athenæums and a rector in the middle schools, professors, regents, and masters. Since 1st June 1853, no one can be appointed a professor or prefect in the athenæums or communal colleges without having the diploma of a professor *agregé* of superior middle instruction. The rectors and regents of the middle schools ought to have a diploma of a professor *agregé* of middle instruction. A master or superintendent must have a certificate of having attended a university, or the diploma of a primary teacher. These conditions are not required of professors of living languages, of writing, music, or gymnastics. Doctors in philosophy, science, and some others are excepted; government may also grant exceptions in particular cases. The prefects, professors, rectors, and regents are nominated by the king, and the masters and teachers by the minister of the interior. The diploma of a professor *agregé* of either degree is bestowed by a special jury after a searching examination. It is given without regard to the place where the candidate has studied. The prefects and rectors reside on the premises, and have the general direction and management of the institutions over which they are placed, the maintenance of order and discipline, and the superintendence of the professors and teachers. Each has to report annually to the minister as to the state and condition of the institution under his care; to register the conduct and progress of the scholars, both from his own observations and from the monthly reports of the professors or teachers, as well as the talents and proficiency of the professors, and the method of teaching followed. They alone can correspond with or report to the board of administration. Every three years a report upon the state of middle education is presented by the government to the legislature.

The salaries of the prefects, rectors, professors, and regents are partly fixed and partly fluctuating; the former being fixed by the government, and the latter arising from the division of the fees, after defraying some necessary expenses, among them in certain proportions. All are obliged to become members of the central *caisse de prevoyance* who are not already members of a similar institution. The annual payment for those whose income does not exceed 1500 francs is 3 per cent., from 1500 to 3000 it is 3½ per cent., and 4 per cent. for all above 3000 francs. Ministers of religion are invited to give or superintend the religious instruction, and to communicate their observations to the *conseil de prefectionnement*.

Athenæums. There are ten royal athenæums in Belgium, two in Hainault, and one in each of the other provinces, viz., in the towns of Antwerp, Brussels, Bruges, Ghent, Mons, Tournay, Liège, Hasselt, Arlon, and Namur. In each of these there are two courses, the one for the humanities and the other for a professional education. The humanity course includes religion, principles of rhetoric and poetry, the Greek, Latin, French, Flemish, German, and English languages, elementary mathematics and physics, geography, and history, with the constitution of the country, drawing, vocal music, and gymnastics. The professional course includes religion, rhetoric, the French, Flemish, German, and English languages; mathematics, including analytical and descriptive geometry, and spherical trigonometry, and as applicable to arts, manufactures, and commerce: the elements of physics, mechanics, chemistry, natural history, and astronomy; book-keeping, the rudiments of commercial law and political economy; geography and history, particularly of Belgium; drawing, vocal music, and gymnastics. This course is divided into two sections, the lower and upper. The lower division, independently of a preparatory class, comprehends three classes, each extending over one year. The upper division has three sections, the commercial, industrial, and scientific, each divided into two classes, and extending over two years. To be admitted into the preparatory classes, the pupil must be at least ten years of age, and at least eleven for the regular classes. The entrance examination for the former comprehends reading, writing correctly to dictation, the legal system of weights and measures, the first four rules of arithmetic, and the elements of the French language; and for the latter are added grammatical and logical analysis and fractions. They also undergo examinations in passing from one class to another.

The government annually allocates the sum of 300,000 francs to the athenæums, in sums varying from 25,000 to 35,000 to each; and 200,000 to the middle schools according to their necessities, the minimum being 2000 francs. The town or commune in which the athenæums or middle schools are situated, has to provide and maintain suitable buildings and furniture, and in the case of athenæums to contribute annually to the extent of one-third of its expenditure. The commune may also in case of necessity be called upon to contribute to the middle school, but not to an extent exceeding one-third of the expense. The fees are fixed by the government on the advice of the board of administration, as well as the conditions of gratuitous or reduced admission.

Middle schools. In the middle schools the branches taught are the French language, with the Flemish or German in the localities where these are used, arithmetic, the elements of algebra and geometry, with land-measuring, and other branches of practical geometry, writing, book-keeping, and the elements of commercial law, the rudiments of the natural sciences, geography, history, drawing, vocal music, and gymnastics. These courses are arranged so as not to occupy more than two years, or three at the most. To some is annexed a preparatory section.

Provincial colleges, &c. The provincial or communal establishments take the name of colleges, or provincial or communal middle schools. Some of these receive government grants, and others are supported entirely by the province or commune. They ought to be based upon the same principles, and teach the same branches as the royal athenæums and middle schools. The administration is in the hands of the province or commune by which the institution has been founded, as well as the nomination of the professors and the other employees. Subsidies by government to these institutions are given, subject to the following conditions, that the programme of studies, the books used, the rules, budgets, and accounts be submitted to the approval of government.

In the end of 1848 there were 8 athenæums, 16 communal colleges, and 12 commercial and industrial schools endowed by the state. Most of these have libraries, museums of natural history, and chemical laboratories. The athenæums and colleges

Belgium.

had then 4438 scholars, of whom 2595 were attending the humanity courses, 163 had bursaries, and 396 were receiving gratuitous instruction. There were 51 unendowed colleges; of these 28 were Episcopal colleges and seminaries, and two exclusively communal. Since then two additional athenæums have been established, and a number of government middle schools, so that there are at present (1853) 10 of the former and 47 of the latter.

Superior instruction.

The superior instruction establishments are the four universities, two belonging to the state, at Ghent and Liège, the Catholic university at Louvain, and the free university at Brussels.

Each of the state universities has faculties of philosophy and literature, science, law, and medicine, including archæology, modern and oriental literature, anthropology, æsthetics, statistics, physical and ethnographical geography, political economy, the higher mathematics, astronomy, mechanics, physics, mineralogy, geology, zoology, botany, &c. The professors are ordinary or extraordinary, the former having a fixed salary of 6000 francs, and the latter of 4000 francs. The government, however, has the power of augmenting the salaries of the ordinary professors to the extent of from 1000 to 3000 francs. In each university there are 8 professors in philosophy, 9 in the sciences, 7 in law, and 8 in medicine. One or two additional professors may be added to each of the faculties in case of necessity. The professors are nominated by the king, and cannot exercise any other profession without the consent of the government. No one can be a professor without having a degree of doctor, or being a licentiate of that branch of education he is appointed to teach. Government may however dispense with these conditions in the case of men of superior merit.

Agregés.

Attached to each university are a number of agregés named by the king. Their title is honorary, and they are chosen from among those students who have most distinguished themselves at the public competitions or final examinations, from professors of middle instruction who have been at least fifteen years engaged in teaching, or from members of the civil or military body of engineers. They are nominally attached to one of the faculties, but are not prohibited from exercising any of the liberal professions, and may give private lessons or repetitions of the courses taught in the university. In the case of any of the professors being unable to perform his duties, a substitute is chosen from among the agregés attached to that faculty. They may be appointed to give lessons or repetitions, in the university, of any of the courses already taught there, under the direction of the professor of that branch, or to give new courses. They receive no salary except when engaged in teaching in the university.

Management.

The universities are under the management of a rector, a secretary, deans of faculty, the senatus academicus, and the board of assessors. The rector is nominated by the king for three years, and has the direction of all academic matters. He enrols the students, superintends their conduct, and receives the oath of the professors and agregés. The secretary is appointed annually by the king from a list of two candidates nominated by the senatus academicus. He minutes the meetings of the senatus and assessors, prepares the programmes, conducts the correspondence, and is keeper of the seal and archives. The deans of the faculties are chosen annually by the professors of each faculty, and have the right of convoking the professors of their faculty. The senatus and the board of assessors are convoked by the rector; the former composed of the professors under the presidency of the rector, and the latter of the rector, secretary, and the deans of faculty.

Attached to each of the universities is an administrator-inspector nominated by the king to see that the funds allocated to the university are properly expended, that the library, museums, &c., are properly taken care of, and that the various functionaries are performing their duties. He has a salary of 6000 francs.

Each student pays annually for enrolment 15 francs, the amount of which is equally divided among the rector, secretary, and the porters, one-third to each. The student then takes out a ticket for the branches of the course in which he intends to take his examinations. For philosophy and literature, and law, the annual ticket costs 250 francs, and 200 francs for the other faculties. The government may, upon the advice of the faculty, grant tickets for special courses, the cost of which is fixed according to circumstances. The sums received for the tickets are divided among the professors and agregés who have given the courses.

Belgium.

There are two vacations in the academic year—the one from the beginning of August to the beginning of October, and the other from the Thursday preceding Easter to the second Tuesday thereafter.

The instructions are given in the French language. The minister of the interior, at least once a-year, calls a meeting of eight of the professors (one for each faculty) to deliberate upon the means of improving the superior education.

Subsidies are accorded by government to the universities for the libraries, botanical gardens, cabinets, &c.; but the towns of Liège and Ghent are bound to maintain the buildings. A report upon the state of the universities is presented to the chambers every three years.

University of Brussels.

The free university of Brussels has faculties of philosophy and literature, of science, of law, and of medicine, courses in which are given by ordinary and extraordinary professors and agregés. Each student pays annually 15 francs for enrolment, and a fee of 200 francs for the courses in any of the faculties. The fee for single classes is generally 50 francs. An annual subsidy of 10,000 francs is allocated to the university by the provincial council of Brabant, and the permanent deputation has the right of annually presenting ten youths of the province for gratuitous instruction. An annual subsidy of 3000 francs is also allocated annually by the communal council of Brussels. It is governed by an administrative council, composed partly of permanent members and partly of members chosen annually by the professors of the four faculties and the former students of the university. This council is presided over by the burgomaster of Brussels, who has a casting vote in its proceedings. It chooses from among its members an administrator-inspector, whose services are gratuitous. The rector is also chosen by the council from among the professors.

Catholic University of Louvain.

The Catholic university of Louvain is governed by a grand rector nominated and revocable by the episcopal body; a vice-rector is also nominated by the episcopal body on the advice of the grand rector. The rector nominates the secretary and other functionaries of the university, and lays annually before the episcopal body a detailed report of the state of the university. The senatus academicus is composed of the professors of the faculties under the presidency of the grand rector. The rectoral council is composed of the vice-rector, the secretary, and the deans of the faculties. The faculties are philosophy and literature, the mathematical, physical, and natural sciences, law, medicine, and theology. The courses of the five faculties are given by ordinary and extraordinary professors and lecturers nominated by the episcopal body on the presentation of the rector. The enrolment fee for the first year is 10 francs, and 5 francs annually thereafter. The annual fee for courses in the faculties varies from 150 to 250 francs, except the theological courses, which are gratuitous. It has an extensive library, cabinets of mineralogy, zoology, &c., and a botanical garden. The number of students attending the university of Ghent at the end of 1850 was 351; Liège, 504; Brussels, 346; and Louvain, 774.

A competition takes place annually between the scholars of superior instruction. Competitors are required to be not above twenty-five years of age, except in the case of medical and law students, who may compete if not above twenty-seven years. The examining jury for each faculty is composed of five members, with an equal number of assistants. Four of the members are nominated by the universities, and the fifth by the government. At these competitions two gold medals are given in each of the faculties. To enable students in poor circumstances but of superior parts to receive a university education, bursaries of 400 francs each are annually given by the state on the advice of the jury of examination. The number of these may amount to sixty. Six bursaries of 1000 francs each may be annually given by the government to those who have taken their degree of doctor with the greatest distinction, to enable them to study in other countries. Two are for doctors in law and in philosophy and literature, and four for doctors in science and medicine. They are given for two years. Besides these there are connected with the universities a number of private bursaries of ancient creation, the management and bestowal of which are in the hands of particular persons or corporations in terms of the acts of foundation.

In each of the faculties there are two degrees—of candidate and doctor, besides the degree of doctor in political and administrative science, of candidate in pharmacy, of apothecary,

and of candidate-notary. No one can be examined for being a candidate in philosophy and literature, or in science, without having attended one of the universities for one year; nor can any one be examined for the title of candidate in law without being one in philosophy and literature; and no one as candidate in medicine without being one in the natural sciences. No one can be a doctor in any branch without being first a candidate in that branch; and doctors in medicine have besides to attend, for at least two years, courses of clinical medicine, surgery, and midwifery. No one can practise as advocate, physician, surgeon, accoucheur, or oculist, without having the degree of doctor. Each of these has to undergo strict examinations on all the branches connected with their professions by juries of examiners. Candidates in pharmacy must undergo an examination upon botany and vegetable physiology, organic and inorganic chemistry, and the elements of physics; previous to which they are examined in Latin, French, the elements of algebra and geometry, and the history of the country. They must, previous to receiving the title of apothecary, show that they have been practically engaged for two years, and been examined in theoretical and practical pharmacy, and in the preparation of drugs.

The juries of examination are formed by the government, and the members are chosen equally from the professors of the government, and of private institutions. The degrees are conferred on the student without reference to the place where he has studied. The examinations are both written and oral. The certificates and diplomas take notice of the appearance made by the student—whether in a satisfactory manner, with distinction, with great distinction, or with the greatest distinction.

There are two sessions of the juries annually, the one beginning on the Monday before Easter, and the other on the first Monday of August. The fees of the different examinations vary from 20 to 150 francs (from 15s. 10d. to L.5, 18s. 9d.), as follows:—the entrance examination of a university student, and the preparatory examination of a candidate in pharmacy, 20 francs; the examination of a candidate, or doctor in philosophy and literature, or the sciences, a candidate in pharmacy, an apothecary, or a doctor in political science, 50 francs; of a candidate in medicine, or each of the three examinations of a doctor of medicine, 80 francs; of a candidate in law, the first examination of a doctor of law, or the examination of a notary candidate, 100 francs; the second examination of a doctor of law, or the examination of a doctor in political science, 150 francs.

Normal schools; primary.

There are two government normal schools for primary teachers, one at Lierre, and the other at Nivelles; the former having thirteen and the latter fourteen professors, with each a rector and a demonstrating gardener. The rectors and professors are appointed by the king. The course extends over three years, and includes, besides the ordinary branches, history, geography, commercial arithmetic, book-keeping, rudiments of the natural sciences, theory and practice of agriculture, horticulture, and arboriculture, hygiene as applicable to children and schools, education theoretical and practical, drawing, music, and gymnastics. During the last year of their attendance they are exercised in teaching in the primary schools of the town. They are also instructed in the keeping of registers, making up of reports, &c. The number of scholars in 1849 at Lierre was 87, and Nevilles 124. Of these 48 received diplomas that year. The expense of these schools to the state for the three years preceding 1849 was 230,663 francs (L.9130). There are also seven episcopal normal schools in which the branches taught are similar to the above, except that the ceremonies of the Catholic church are more particularly inculcated. The chief diocesan nominates the rectors and professors. The course lasts for four years. The number of scholars in 1850 was 306.

Bursaries of 200 francs each are annually given by government to assist poor students attending the normal schools who give proofs of their aptitude. These may be continued to them after leaving school, during their noviciate as assistants or teachers.

Each province has one or more institutions for the training of female teachers, and bursaries are provided for young females desirous of entering such institutions. The number of scholars at the end of 1850 was 114.

Middle.

Students of promise who have taken diplomas at either of the government primary normal schools may be admitted to the normal school of middle instruction at Nivelles. The number of students to be admitted is annually fixed by the minister. The course is for one year, and includes the French language, mathematics, land-measuring, the elements of physics, mechanics, and chemistry, and pedagogy. The diploma of professor agregé of middle instruction is given after two searching examinations by a jury of seven members. It mentions the manner in which he passed his examinations. The fees for the two examinations amount to 70 francs.

For training teachers for the superior middle institutions, there are the normal school of the humanities at Liège, and the normal school of the sciences at Ghent. The number to be admitted is determined annually by the minister. They must be young men, between 18 and 23 years of age, of superior talents, qualifying them to perform creditably the duties of professor. Previous to admission they have to produce certificates of character, and to be examined both orally and by writing by a jury of five members; and the number to be admitted is taken from among those that stand highest by the examinations. The branches taught in the school at Liège extend over three years, and include the Latin, Greek, French, and English languages; antiquities, ancient and modern history and literature; geography, ancient, modern, and physical; philosophy, the principles of general grammar, and pedagogy. They undergo an examination annually; and on passing their final examination, they receive a diploma of professor agregé of superior middle instruction for the humanities. Where the branches of the normal school are the same with those taught in the university, the scholars generally attend there. The rector has a salary of 6000 francs, and the professors unconnected with the university from 3000 to 5000 francs. Each student has to pay a fee of 500 francs, but fifteen bursaries of 500 francs each are given for one year to the poorer students, and which may be continued for a longer period on the advice of the rector. The recipients become bound to act as professors in one of the middle schools for five years.

The branches taught in the normal school of sciences at Ghent also extend over three years, and include the higher departments of mathematics, physics, mechanics, chemistry, natural history, &c. The degree of professor agregé of middle superior instruction for the sciences is conferred on those passing the final examination. There are five bursaries of 500 francs in connection with this school.

Engineering school.

Attached to the university of Ghent is a school for civil engineers. The preparatory course extends over two years, and comprehends the mathematical, physical, and natural sciences necessary to the subsequent courses. The special course is divided into two sections, the one for engineers of roads and bridges, and the other for architectural engineers. This course continues for two or three years, and the pupils undergo strict examinations both on entering and leaving. During the summer they are generally sent to visit, or to assist in the various public works that may be going on. The third course, which lasts for three years, is for industrial engineers or persons engaged in arts or manufactures. They are instructed in the application of the various sciences to the arts and manufactures, or trade, particularly to the mechanical arts.

Mining school.

Similar to the above is the mining school attached to the university of Liège. The first course is preparatory to the other two. The special course includes all the branches necessary to a mining engineer. The third course is for those desirous of obtaining a knowledge of mining, minerals, &c., more particularly as connected with the arts and manufactures. This last course extends over four years.

Military schools.

There is a military school at Brussels for training officers for the army. Candidates for admission must be between sixteen and twenty years of age, except in the case of persons in the army, having entered it before the age of twenty, and been at least two years in active service, who are admitted till twenty-five. They are admitted by public competition. The courses are divided into two sections; the one, which extends over two years, is preparatory to the second, which also extends over two years, and is divided into special branches qualifying for the infantry, cavalry, or marines. For the first two years students pay for their education and maintenance 800 francs annually. Those from the army receive their pay during their attendance. The king gives annually twelve bursaries, which may be divided into half bursaries. On entering the second section, they become bound to serve for six years, cease to pay for their maintenance, and receive commissions as sub-lieutenants. They are examined annually, and

Belgium.

the last year by a jury of military officers appointed by the king.

A school has been established in Lierre for the purpose of educating the sons of the military for subalterns. They are admitted from ten to fourteen years of age, and are bound to serve in the army till their twenty-fourth year. Those, however, who on attaining their fifteenth year are considered unfit for the service are dismissed, but if meritorious they may remain till their sixteenth year, and be provided with situations. Besides the ordinary branches of education, they are taught drawing, geometry, music, dancing, fencing, swimming, gymnastics, and military exercises. The course extends over five years, and the pupils generally enter the army about the age of sixteen. They are placed in the army according to their proficiency, some as sub-officers and corporals, others as common soldiers. The pupils in 1850 were 480.

Each regiment has a regimentary school for training young men in the army for subalterns; and a number of evening schools for affording the means of education to the soldiery. The regimentary schools are under the superintendence of the brigade majors of the territorial divisions, who examine the schools in their districts at least once a-year, and report to the minister. Attendance at one of these schools is obligatory on all subalterns and corporals whose education is not complete, according to their position. The scholars in 1848 were 3857. Special courses are also given to those who intend to compete for admission to the military school. The success of these courses is evident from one-third, and sometimes one-half, of those admitted to that school being from the army. A riding school was established in 1847 for instructing officers of the cavalry, artillery, and staff, in the art of riding, as well as those destined for instructing the troops of horse. The former attend for one and the latter for two years. Attached to the riding school is a school of farriery.

There is also a school of pyrotechny, under the direction of a superior officer of artillery, with a certain number of officers and subalterns. Eight well-educated young men are sent from each regiment of artillery to attend this school. The course continues for two years, and comprehends arithmetic, practical geometry, drawing, theoretical and practical pyrotechny and chemistry.

Navigation schools.

Schools of navigation have been established at Antwerp and Ostend for furnishing properly educated masters for merchant vessels. Instruction is given gratuitously in navigation and the branches connected with it, as arithmetic, geometry, trigonometry, nautical astronomy, &c.; with the elements of commercial law, as applicable to merchant vessels, the English language, and the manœuvring, rigging, and trimming a vessel, both theoretically and practically. Certificates of qualifications as masters or mates are given by a jury of examiners.

The Royal Institution of Messines is for the education of daughters of military men who have died or been disabled in the service of their country. They are admitted from seven to fourteen years of age, and remain till their eighteenth year. They are instructed in branches necessary to qualify them as governesses, domestic servants, &c. Situations are provided for them on leaving. Some of them are trained as teachers for infant-schools, and for this purpose an infant-school has lately been formed in connection with the institution. The number in 1851 was 230.

Agricultural school.

A school of agriculture is established at Tirlemont, to which scholars are admitted from fifteen to twenty-two years of age, after passing an entrance examination. The course extends over three years, and includes the elements of mathematics, physics, mechanics, mineralogy, geology, botany, chemistry, zoology, agriculture, land-measuring, rural architecture, and veterinary science. There is a farm of 115 hectares in connection with the school. The annual fee is 400 francs. There are seven other similar establishments throughout the country, to some of which bursaries are attached; a practical school of horticulture and arboriculture at Yilvorde; and a theoretical and practical school of horticulture at Gentbrugge (East Flanveterinary science, in connection with which there are several bursaries.

It has lately been proposed to establish at Antwerp a kind of commercial university for special instruction in the commercial sciences. It is expected that this will be in operation next year (1854).

Belgium.

The academies and schools of design, painting, sculpture, &c., are divided into three branches. 1. The royal academies of the fine arts, in which painting, sculpture, architecture, and engraving, are taught in the most efficient manner; 2. Academies of design established in the principal towns, and giving instructions in designing, architecture, and the principles of geometry and perspective drawing; 3. Schools of design established in all the larger towns for instructing young persons and artisans in the elements of designing and architecture. In 1850 there were 41 such academies and schools in the kingdom, having 164 professors, and 7450 pupils.

Academies and schools of design.

Academy of fine arts.

The Royal Academy of the Fine Arts at Antwerp is principally intended to afford gratuitous instruction in painting, sculpture, architecture, and engraving, and to propagate and encourage a taste for the fine arts. The programme of studies includes portrait, historical, and landscape painting, sculpture, civil and naval architecture, geometry, designing, engraving, &c., with lectures on anatomy, perspective, history of architecture, &c. In 1850 there were 1060 scholars. A competition in one of the branches of the fine arts is annually held in Antwerp, the laureate at which receives a pension of 2500 francs annually for four years, to enable him to perfect himself in his art in Germany, France, and Italy. The second prize is a gold medal of 300 francs. The Royal Academy of the Fine Arts at Brussels, is an institution similar to that at Antwerp. Instruction is gratuitous, and the vacancies are filled up by competition. The students in 1850 amounted to 761.

Musical conservatory.

The Royal Musical Conservatory at Brussels is under the direction of the minister of the interior, aided by a commission of seven members nominated by the king, with the burgomaster of Brussels as honorary president. The instruction is gratuitous, and includes vocal and instrumental music, composition, and the Italian language. There are thirty professors, and the number of scholars in 1850 was 299. There are six bursaries of 250 francs, and ten of 125 francs, in connection with this institution. There is a similar establishment at Liège, with (in 1850) 300 scholars. There is also one at Ghent unconnected with the government; scholars (1850) 308. Music, both vocal and instrumental, is much cultivated in Belgium, and musical schools and societies are established in almost all the principal towns, and throughout the country. In the end of 1851, there were 461 instrumental music societies, with 12,397 members, and 258 vocal, with 7062 members. A competition in musical composition takes place every two years at Brussels, the laureate receiving a pension of 2500 francs for four years, to enable him to study in France, Germany, and Italy. The second prize is a gold medal of the value of 300 francs.

Royal academies.

Belgium possesses a great number of learned societies, as the Royal Medical Academy, the Royal Academy of Science, Literature, and Art, &c.

There is a government inspector general of science, literature, and art, who has the general superintendence of that department, under the minister of the interior. He visits the exhibitions of the fine arts, and informs the government of such works as merit a place in the National Museum, and of young artists whose talents and proficiency render them worthy of notice. Under him are two administrative boards, the one for literature and science, and the other for the fine arts.

The Royal Medical Academy has its seat at Brussels. It is divided into six sections, each composed of six titular and three assistant members; and has twenty-four corresponding and an indefinite number of honorary members. Each of the sections has certain branches of medical science assigned to it. A meeting is held every month except August, and a general meeting once a-year. The academy answers any questions that may be proposed to it by the government, upon matters connected with public hygiene, and makes researches in all subjects connected with or tending to advance medical science. Its proceedings are published annually. A certain number of gold medals are given annually by the academy for the best essays on prescribed subjects. It receives an annual grant of 20,000 francs from the state.

The Royal Academy of Science, Literature, and Art, also has its seat at Brussels. It is divided into three classes, for the sciences, literature, and the fine arts; the first two are each subdivided into two sections, and the last into branches for painting, sculpture, engraving, architecture, and music. Each class is composed of thirty members, fifty foreign associates, and not more than ten native correspondents. The aca-

demy has a general meeting once a-year. Each of the classes meets monthly, and has also an annual public meeting for conducting the general business and proclaiming the authors of the prize essays. Each class proposes annually certain subjects for essays, to which gold medals of the value of 600 francs are adjudged. The academy receives an annual grant of 40,000 francs from the state. Connected with this academy is a royal commission of history for the purpose of searching for, and editing old chronicles and documents tending to throw light upon the early history of the country. In this patriotic object it is zealously seconded by government.

Royal observatory.

The Royal Observatory for astronomical and meteorolgical observations is under the management of a director and four assistants. It has published an annual since 1834. With the view of precisely determining the measure of time, a small lunette meridian has been constructed in each of the cities of Antwerp, Ostend, Bruges, Ghent, and Liège; and grand meridians are placed on the walls of edifices in numerous other towns. In the observatory are instruments specially provided by government for the use of young men desirous of making meteorological or astronomical observations. Premiums and medals are given to Belgians for useful discoveries, inventions, or improvements in instruments, &c.

Museums.

The Royal Museum of Brussels, for the reception of objects in natural history belonging to the state, is open to the public on Sundays, Mondays, and Thursdays. There is also a museum of industry containing models and plans of machines used in arts, manufactures, and agriculture. Annexed to this museum is a school where instruction is given gratuitously in the construction of such machines. It possesses also a chemical laboratory, library, &c. There is also a royal museum of war instruments at Brussels, open to the public on Sundays and holidays. The royal museum of painting and sculpture is under the direction of a commission, composed of a president and six members nominated by the king, and charged with the collection of works of ancient and modern masters for the museum. It is open to the public on Sundays, Mondays, and Thursdays. A triennial exhibition of works of living artists, Belgian and foreign, in painting, sculpture, engraving, architecture, and lithography, is held at Brussels. The exhibition of 1851 contained 1479 works by 792 artists, of whom 314 were foreign. There are similar exhibitions held in Antwerp, Ghent, Liège, Bruges, &c. The geographical establishment at Brussels has a considerable collection of books and maps, a garden, herbarium, collection of rocks, lava, fossils, &c.

Libraries.

Besides the libraries belonging to different societies, associations, &c., there were in 1849 nineteen public libraries in Belgium. The principal of these is the royal library of Brussels. It then contained about 180,000 volumes, 19,668 manuscripts, 30,000 engravings, and 14,000 medals and coins. The average annual increase is upwards of 3000 volumes. This is the only library that receives copies of copyright works. The public library of Ghent is connected with the university. It has 60,000 volumes and 600 manuscripts, besides pamphlets, &c. The average annual increase for the last ten years has been 650 volumes and 5 manuscripts. The Liège public library has 58,000 volumes, about 26,000 pamphlets, and 430 manuscripts; annual increase about 700. The public library of the Louvain university is the most ancient in Belgium, and is particularly rich in works of ancient history, theology, and literature, including Hebrew, Greek, Latin, and Oriental. In 1846 it had upwards of 60,000 volumes and 319 manuscripts. The library of Tournay has 26,230 volumes and 200 manuscripts; Antwerp 20,000 volumes; Namur 17,000; Mons 15,000; Bruges 10,500; Ypres 9500; and the rest a smaller number. These libraries are open daily for consultation, and in almost all of them volumes may be lent out at the discretion of the conservators. Nor has this occasioned any serious loss. Since 1838 about 10,000 volumes have been lent out of the library at Brussels, and of these only two insignificant volumes have been lost. From 1845 to 1850, 19,805 volumes had been lent out of the library of Ghent, of which only 20 were lost or destroyed, which were replaced at the expense of the borrowers. The number of works consulted in the rooms of this library, from 1st October 1849 to 1st July 1850, was 12,772; and 3494 were lent out.

Archives.

The archives of Belgium contain a great number of interesting and valuable documents connected with the history of the country. These are carefully preserved, classified, and inventoried. The general archives of the kingdom at Brussels contain upwards of 100,000 documents, and the archives of Antwerp upwards of 70,000. Those of the provinces of West and East Flanders, Hainault, Liège, and Namur, are ancient and important. The archives of the city of Bruges, at one time the grand commercial entrepôt of Europe, contain a number of valuable papers bearing upon the events of which this city was the theatre in the middle ages. Unfortunately they do not go further back than 1280, the previous documents having been all destroyed by an extensive fire in that year.

Periodicals.

In 1848, 202 journals were published in Belgium. Of these 18 appeared seven times, 20 six times, 20 three times, 12 twice, and 132 less than twice a-week; 137 were in the French language, 52 in Flemish, 1 in English, 1 in German, and 1 in Polish; 122 were political, 37 literary or scientific, and 33 exclusively devoted to advertisements. The stamp duty having been abolished in 1848, it is impossible to give the number since that period, but it has been much increased. The total number of newspapers stamped during the first quarter of 1848 was 2,781,458, producing a duty of 105,605 fr. The number of literary and scientific reviews and magazines in 1850 was 93.

Hospitals, &c.

The benevolent and charitable institutions of Belgium are numerous and open to all. The duty of supporting these falls in the first instance upon the commune, afterwards upon the province, and finally, in case of necessity, upon the state. They are divided into three classes. 1. Those affording assistance or an asylum to the poor in the case of age, infirmity, disease, want of work, &c., including dispensaries, foundling and maternity hospitals, deaf-mute, and blind institutions, &c. 2. Those more particularly destined to the prevention and suppression of vagabondage and beggary, as the depôts of mendicity and the reform schools. 3. Those specially intended to foster a spirit of independence and foresight among the working classes, as savings-banks, assurance and mutual assistance societies.

Every town of importance, and many of the rural communes have hospitals for the aged, infirm, and indigent. Asylums for incurables are also numerous, but much less so than the former. Farm hospitals have been established in the rural communes of the two Flanders, where the inmates contribute by work to their own maintenance. They form small agricultural colonies of old people and children, mutually aiding and assisting each other. The products of the farms are generally equal to their maintenance. There are fourteen such establishments in West Flanders, with (1851) 1052 inmates; and fourteen in East Flanders.

Foundling hospitals are established in Antwerp, Brussels, Louvain, Bruges, Ostend, &c. The children generally remain only for a short time in the hospitals. They are pensioned out to inhabitants of the rural communes till their twelfth year, at which period the wardship of the hospital terminates. Inspectors are appointed to visit the children quarterly, to report upon their physical condition, see that they are attending schools, &c. The number (1850) was 7574. There are maternity hospitals at Brussels, Louvain, Ghent, Liège, Bruges, Nieuport, and Tournay, in several of which courses of midwifery are given. Maternity societies for aiding females with money, medicine, &c. are formed in many of the towns. In 1846 there were 58 lunatic asylums, 18 public and 40 private, having in all 3143 patients. A colony of lunatics has been formed in the commune of Gheels, province of Antwerp, where, under the direction of a permanent committee, they are pensioned out among the inhabitants, and generally employed in agricultural labours. In 1851 they amounted to 931.

In 1835 the number of the deaf and dumb was 1746, of whom 1376 were from birth, and 370 by disease or accident; of the blind was 3892, 256 from birth, and the rest by disease or accident. In 1850 the deaf and dumb in seven of the provinces (East Flanders and Hainault not given) amounted to 1265, and the blind to 1793. There are in all ten institutions for these, in Brussels, Bruges, Ghent, &c. There are ophthalmic institutions in Brussels, Mons, and Liège.

To prevent the misery, and frequently the crime, arising from the want of employment among the working classes, charity workshops have been established in Ghent, Liège, and other towns. These are accessible to all workmen without employment, and in poor circumstances. The able bodied are paid according to their work, and the aged and infirm according to their necessities. The workshops of apprenticeship and improvement are intended not only to supply work to the unemployed, but principally to initiate the people in the exercise of new or improved branches of industry, and to instruct the young men in some trade or profession by which they may be able to gain an honest maintenance. They have been found of great benefit to many of the poorer classes who would otherwise have been brought up as vagrants and beggars. The apprentice-

ship generally lasts from four to six months. Although the means of obtaining a primary education is provided in connection with these establishments, yet their time is too much devoted to manual labour to derive much profit from the latter. Many thousands are employed in these workshops. Similar to these are the manufacturing schools, intended principally for girls, where they are employed in the manufacture of lace, &c. These are supported partly by the state and partly by the province and communes.

There are five depôts of mendicity or workhouses in the kingdom, at Bruges, Hoogstraeten, Mons, Reckheim, and the Cambre (commune of Ixelles). In December 1850 they contained 3478 persons. The average daily expense of each is 50 centimes (4½d.) A reform school was founded in Ruysselede, in 1848, for male vagrants and mendicants under eighteen years of age. It contained (1851) 500 members, employed in cultivating a large farm of 128 hectares. At a short distance is a similar institution for girls.

In each commune is a *bureau de bienfaisance*, for assisting the poor with money, food, clothing, &c., and, where there are no hospitals, providing them with medical attendance and medicines. It also contributes to the maintenance and education of poor children, foundlings, deaf-mutes, and lunatics. In 1850, 205,516 families, consisting of 901,456 persons, were aided by these charities, and the amount expended was 6,331,240 fr. This, however, cannot be taken as a criterion of the true condition of the people, as many who do not require it take advantage of the society for receiving gratuitous education or medical attendance.

Twenty-two towns in Belgium are provided with *Monts de piété*, charitable institutions for lending money to the poor, upon the security of pledges. Each *Mont de piété* is directed by a board of five members nominated by the communal council. In 1850, 1,307,711 articles were deposited or renewed, 1,253,698 retired, and 51,857 sold; the money lent amounted to 7,775,668 fr.

A savings-bank is established in the principal town of each province, by the Society for the Encouragement of National Industry. The number of depositors in these in 1851 was 23,302, and the amount deposited was 17,024,396 fr. They have also been established in all the manufacturing towns, and in many of the rural communes. *Caisses de prévoyance*, both general and for special classes of workmen, are also numerous. Mutual assistance societies to succour the members in sickness, pay their funeral expenses, and aid their families, are numerous. A report presented to the Chambers in 1851, shows that the number of these was 211, having 24,367 members.

Agriculture.

Since 1830 the agricultural state of the country has been much improved. A superior council of agriculture, composed of two delegates nominated annually from each of the provincial commissions of agriculture, and a president, vice-president, and secretary, appointed by the minister of the interior, is specially charged with the promotion and superintendence of the agricultural interests of the country. In each of the provinces is an agricultural commission of practical men, nominated by the king, one from each of the agricultural districts in the province, and a veterinary surgeon. They encourage the introduction of improvements in the different branches of agriculture, and report annually to the government upon the state of agriculture in their provinces. Each district has an agricultural committee which meets twice a-year. Every five years a grand agricultural exhibition of horses, cattle, agricultural implements, and produce, is held in Brussels, at which numerous gold and silver medals, &c., are given as prizes. Local exhibitions are also held frequently in the various districts. In each of the agricultural districts there is at least one veterinary surgeon for superintending and reporting to the governor of the province upon epidemics and other diseases among cattle. No one can practise as a veterinary surgeon without having obtained a diploma after an examination by jury in the various branches of the art. Indemnities are given by government to agriculturists for losses sustained in crops, cattle, &c., to an extent varying from one-third to one-tenth of the loss.

The agriculturists above twelve years of age, including female servants, form one-fourth of the entire population. Females are extensively engaged in agricultural work, being in 1846 to the males as 61 to 100. In 1846 the number of horses was 194,537, of cattle 1,203,891, sheep 662,508, swine 496,565, goats 110,060. To improve the breeds of horses a government stud of about 40 stallions has been formed at Tervueren. These are annually sent out to stations in the different provinces.

The cultivated land of Belgium amounts to 2,603,036 hectares, or 6,432,477, acres, of which 1,423,453 hectares are in the hands of the proprietors, and 1,179,583 are let to tenants. In West Flanders 85 per cent. are tenants: in Luxembourg three-fourths are in the hands of the proprietors; and in the provinces of Antwerp, Brabant, and East Flanders, three-fourths are let to tenants. It is divided into numerous and mostly small patches (nearly 600,000). Of these 43 per cent. do not exceed 50 ares, or about 1 acre and a quarter, 12 above 50 ares and not exceeding one hectare, or 2 acres and a half, 29 not exceeding 5 hectares, 7·47 not exceeding 10 hectares, and less than 8 of greater extent. The Belgians, particularly in Flanders, are averse to the introduction of improvement, in their agricultural operations, and their implements are generally rude and clumsy. Their lands are however cultivated with great care and are very productive. The proportion to 1000 hectares of the various kinds of land in 1846 was:—

Producing Cereal and Farinaceous crops, . . .	337·34
... Industrial plants, ...	25·22
... Leguminous fruits, ...	26 38
... Alimentary roots, ...	50·66
... Fodder, ...	59·83
Prairie land, ...	139·19
Fallow, ...	31·08
Garden, ...	19·17
Wood, ...	186·58
Uncultivated or only periodically, ...	124·55

Of the cereal and farinaceous crops rye is the most extensively cultivated, and forms an important article of food for the working classes. Wheat and oats are also extensively cultivated, the former particularly in the provinces of Hainault, Brabant, and West Flanders. Comparatively little barley is raised.

The industrial plants are hops, chicory, tobacco, rape and other oleaginous plants, hemp, flax, madder, teasel, beet, &c. Of these the most extensively cultivated is flax, principally in the two Flanders. Tobacco was much more extensively grown a few years ago; at present it is now almost entirely confined to the two Flanders and Hainault. The chicory plant is principally raised in Hainault. The cultivation of beet for the extraction of sugar is continully increasing, and numerous establishments have been formed for its preparation.

The leguminous plants, pease, beans, and tares, are used principally as fodder for cattle: the most common are beans.

The beet-root is even more extensively cultivated as fodder than as an industrial plant, particularly in the provinces of West Flanders, Liège, Hainault, and Brabant. Turnips are, next to the potatoes, the most extensively cultivated of the alimentary roots. In 1846 the extent of ground occupied in potatoes was 115,062 hectares. The disease that has affected this article of food, though it has diminished the amount produced, has much enlarged the extent of its cultivation, being now probably from 30,000 to 40,000 hectares more than in 1845. It has risen much in price, so that from being one of the principal articles of food for all classes it has become one of the most expensive. The fallow ground, formerly considerable, is now only of small extent, being principally sown in fodder crops. Clover is the principal fodder crop. The prairies are partly used as pasture, and partly mown. Draining, and clearing the *bruyeres*, are now actively carried on under the direction of government.

Minerals.

Belgium is rich in various kinds of minerals, as coal, iron, calamine, &c., forming a valuable source of employment to many thousands of its inhabitants.

Under the minister of the interior the mines are superintended by a corps of mining engineers, composed of an inspector-general, chief and ordinary engineers, sub and aspirant engineers. Each of the six mining districts has an ordinary engineer, and each of the two divisions a chief engineer. A sub-engineer is appointed over a certain number of mines. Vacancies in the higher orders of the corps are filled up from among those who have served at least three years in the next lower grade. The council of engineers gives advice on all questions submitted to them connected with the administration and working of the mines.

Belgium is almost traversed from west to east by beds of coal. These may be divided into two great basins. The western basin is the most important, and has an estimated extent of 90,051 hectares, or about 222,400 acres; 75,725 in the province af Hainault, and 14,326 in Namur. The extent of the eastern bed is estimated at 44,062 hectares,—41,745 in the province of Liège, and 2317 in Namur. All varieties, from anthracite to the richest gas-coal, are found. In 1850 there were 153 mines in Hainault, 40 in Namur, 116 in Liège, and a small one in Luxembourg. The number of persons employed was 36,002 men, 4045 women, 6559 boys, and 2363 girls: 5,820,588 tons of coals were extracted, valued at 46,471,393 fr.; the expense of working was 40,310,619 fr. The coal is principally consumed in the country: 1,439,473 tons were sent to France, 197,569 to Holland, 14,410 to Prussia, and 7644 to other countries.

The iron districts are the arrondissement of Charleroi, and the provinces of Namur, Liège, and Luxembourg. Besides the iron mines in Charleroi, Hainault contains a copper mine, commenced in 1849, calamine and blende in the communes of Solre-St-Gery and of Barbencon. Iron is also found in small quantities in the arrondissements of Mons and Tournay. In Namur the iron ore is rich and plentiful, and constitutes the principal mineral wealth of the province. The beds of pyrites are daily becoming of greater importance as the mining is carried to a greater depth. Veins of lead and zinc are

Belgium.

also wrought to a considerable extent, as is also a bed of oolitic oligist at Uezin. The iron mines of Luxembourg are much inferior to those of Namur. The principal are those of Durbuy, Ruette, Grandcourt, Halanzy, and Musson. At Couthuin, in the province of Liège, a prolongation of the bed of oolitic oligist at Uezin is wrought, and at Angleur an important bed of limonite. The ferruginous basins of Theux and La Reid are of the greatest importance, both as public works, and from the quantity of ore that they furnish. Lead and zinc are found here almost always in the same bed. Alumiferous schist is common in several parts of the province. The manganese mine at Bihain has been abandoned. In 1850 the different metallic mines yielded 7308 tons of blende, 62,193 of calamine, 3854 of lead, 4084 pyrites, and 472,883 tons of (buddled) iron. Comparing the average annual produce from 1841 to 1845, with that from 1846 to 1850, we find a considerable increase in each; in calamine of 23,767, lead 2858, pyrites 2871, and iron 261,080 tons. The mining of blende only commenced in 1845, in which year it amounted to 264 tons. The number of workmen employed in these mines was 5695.

Marble is abundant in many parts of Belgium, and the black marbles, as those of Dinant and Gochene, may rival the finest productions of other countries. There are numerous quarries of various kinds, as freestone, granite, limestone, slate, &c. The principal quarrying provinces are Namur and Hainault. They gave employment (1846) to 7892 persons.

In 1850 the stationary steam-engines in the kingdom were 2040, of 51,055 horse-power, being double that of 1838. Most of these (30.969 horse-power) are employed in working the mines. Low-pressure engines are rapidly disappearing. Of these there were 289 in 1844, and only 89 in 1850. The number of steam-vessels (1850) was only 13, having a total of 1000 horse-power; and of locomotive engines on the different government railroads 170, of 10,703 horse-power.

Manufactures.

The total value of manufactures imported in 1850 was 38,646,000 fr., and exported 102,162,000, being an increase of 35 per cent. since 1841. The number of persons employed in the various manufactures in 1846 was 314,842, being 207,784 adult males, 40,673 adult females, 36,356 boys under sixteen years of age, and 30,029 girls.

The number of works in 1850 for the preparation of iron was 351, steel 2, lead 8, copper 20, zinc 19, alum 2, glass 35; 13,223 workmen were engaged, and the value of the produce was 51,261,457 fr. There is a decrease of 37 per cent. on the average of the three years preceding 1848, as compared with the three subsequent, in the iron manufacture. During the former period the demand for iron was great, and the prices were augmented by the number of railways constructing in Belgium and other countries.

Notwithstanding many vicissitudes, flax is the most ancient, and still forms one of the most important branches of industry in the country. In 1846, 29,872 hectares of land were occupied in the cultivation of flax, and 1712 in that of hemp; the various manufactures of these gave employment to 60,023 persons, viz.:—18,563 men, 7348 women, 3852 boys, and 20,793 girls. In 1850 the value of the exports and imports was as follows:—

	Imported.	Exported.
Raw flax	5,825,000 fr.	17,138,000 fr.
... hemp	676,000	26,000
Flax and hemp yarns	896,000	5,027,000
... ... cloths	191,000	10,082,000
	7,588,000	32,273,000

Cotton also forms an important branch of industry, and is at present in a more flourishing condition than at any former period. In 1846 it employed 7552 men, 3129 women, 2494 boys, and 1305 girls. In 1850 the exports and imports were as follows:—

	Imported.	Exported.
Raw cotton	16,504,000 fr.	4,587,000 fr.
Cotton yarn	289,000	455,000
Cotton cloths	3,448,000	8,595,000
	20,241,000	13,637,000

The manufacture of woollens forms also an important branch of industry. The wool for this purpose is principally imported from Prussia, Saxony, &c., the native produce being small in quantity and chiefly used in hosiery. It employed (1846) 10,134 men, 4686 women, 2076 boys, and 1257 girls. Imports and exports (1850):

	Imports.	Exports.
Wool	16,941,000 fr.	1,642,000 fr.
Woollen yarn	3,419,000	1,320,000
... cloths	8,398,000	16,309,000
	28,758,000	19,271,000

The manufacture of silk gave (1846) employment to 655 persons; value of imports (1850) 11,353,000 fr., exports 637,000 fr. Although the cultivation of the mulberry tree for the breeding of silkworms has been carried on since 1826, it has yet made little progress. The lace, ribbon, and hosiery manufactures employed 1494 males, 675 females, 501 boys, and 337 girls. Imports and exports in 1850:

Belgium.

	Imports.	Exports.
Lace	893,000 fr.	41,000 fr.
Ribbons	493,000	58,000
Hosiery	298,000	513,000
	1,684,000	612,000

The excisable manufactures are beer, vinegar, &c. The number of breweries in the kingdom in 1850 was 2899, employing 6766 persons, and of vinegar works 84, employing 105 persons. The amount of excise received from these establishments was 6,436,931 fr. Distilleries 587, workmen 1647, excise 3,839,741 fr. Salt works 318, workmen 495, excise 4,416,372 fr. Refineries of foreign sugar 50; manufactories of beet-root sugar 28, excise 3,169,509 fr. In 1846 2122 hectares of land were occupied in beet-root for sugar, and 4190 persons were employed in its manufacture. The principal of the other branches of industry, with the number of persons employed in each, as shown by the general census of 1846, are as follows:—The manufacture of nails, particularly in the provinces of Liège and Hainault, employs 6786 persons. The manufacture of bricks and tiles, the chief seat of which is in the province of Antwerp, employs 8203 persons. The manufacture of fire-bricks was introduced in 1836, and has since been making great progress. The manufacture of porcelain and earthenware goods employs 1573 persons; glass and crystal works 3683; paper-making 2169; printing 2026. The maritime fishing employs 207 boats of 5800 tons, and 1224 men. An extensive manufactory of fire-arms at Liège employs 1782. The less extensive manufactures are oil, soap, chemicals, leather, ropes, &c. The number of failures in 1849 was 132, in 1850, 113, and in 1851 to 15th August 83. Eleven vessels of 3333 tons were built in Belgium during 1850.

In 1851 Belgium possessed 149 trading vessels, of the aggregate burden of 30,577 tons.

Commerce.

The value of the imports and exports for the years 1849, 1850, and 1851, was as follows:—

	Imports.	Exports.
1849	405,249,000 fr.	374,776,000 fr.
1850	423,117,000	411,292,000
1851	418,555,325	401,176,052

In 1851 the imports by Belgic vessels were valued at 44,702,097 fr.; by foreign 124,736,164 fr.; and by land and rivers 249,117,064 fr. Exports by Belgic vessels 24,107,306 fr.; by foreign 81,326,815 fr.; and by land and rivers 295,741,931 fr. The laden Belgic vessels entering were 402 of 70,261 tons, and foreign 1591, of 229,771 tons. The laden Belgic vessels leaving were 351 of 62,996 tons, and foreign 1168 of 161,314 tons. The number entering in ballast was 149 of 17,434 tons: 1359 vessels entered the port of Antwerp, 448 Ostend, 234 Ghent, and 101 Nieuport. The imports are principally from France, England, Holland, and the United States, and the exports principally to France, Holland, Prussia, and England.

The imports are divided into three classes, those for direct consumption in the country, those in transit, and those brought into warehouses to be either consumed in the country on paying the duties, or exported. The value of goods imported for consumption, and of the productions of the country exported was for the above three years as follows:—

	Imported.	Exported.
1849	206,777,000 fr.	179,054,000 fr.
1850	211,923,000	210,033,000
1851	218,085,070	200,129,626

These are divided into three branches. 1. *Premières matières*, articles consumed in the state in which they are found, as coals, &c.; 2. Articles of food; and 3. Manufactures. The imports and exports of 1851 so divided, give—

	Imports.	Exports.
Premières matières	93,663,110 fr.	97,742,481 fr.
Food	84,362,885	26,258,285
Manufactures	40,059,075	76,128,860

The value of the goods in transit for the years 1850 and 1851 was—

	Direct.	By warehouse.
1850	175,553,000 fr.	25,706,000 fr.
1851	175,104,292	25,942,134

Of the latter the value exported by Belgic vessels was 7,046,655 fr., by foreign 28,712,479, and by land and canals 165,287,292 fr. Although there is a slight decrease in 1851 as compared with 1850, in comparing 1850 with 1841 we find an increase of 259 per cent. The value of goods in warehouse at 1st January 1851 was 26,626,000 fr.; entered during that year 65,006,000; taken out for consumption 39,922,000; for export 25,942; and 25,480,000 were in bond at the end of that year.

The first five months of 1853, as compared with the same period

Belgium.

of 1852, show a considerable decrease in the importation of many of the principal articles of trade, as coffee, cottons, rice, tobacco, &c. On the other hand, however, the increase in the articles of exportation is even more marked. In the latter there is an increase of 270,000 fr. in portable arms, 16,264 tons in pig iron, 882 tons in wrought iron, 540 tons in nails, and 463 tons in iron used in machines. The exportation of bar iron and rails during the first five months of 1853 amounted to 8447 tons. During the whole of 1852, it was only 7325 tons, and during 1851 only 4015 tons. The increase in the linen and cotton manufactures, and in sugar, is also very considerable. A company has been formed for the establishment of regular steam communication between Antwerp and New York, which will undoubtedly give a great stimulus to trade in Belgium. It is expected to be in operation by May 1854, and except during the first year will have two departures monthly from each side of the Atlantic.

Chambers of Commerce.

There are nineteen chambers of commerce and manufacture established in the principal towns, the members of which are nominated by the king from a triple list of candidates presented to him by the chambers. The members of each vary in number from nine to twenty-one, one-third going out annually. They present to the government or legislative chambers their views as to the best means of increasing the commercial and industrial prosperity of the country, report annually upon the state of their districts, and give useful information or direction to the provincial or civic authorities under their administration.

Commercial Association.

Belgium possesses a great number of commercial and financial associations. In 1851 there were no fewer than 191 legally authorized joint-stock companies for carrying on public works, or enterprises, having a united capital of 880,347,298 fr. Of these 12 were assurance companies, 12 private banking companies, and 14 railway companies. It has eight commercial exchanges, under the direction of government, namely, in Antwerp, Brussels, Ghent, Bruges, Ostend, Mons, Termonde, and Louvain. In 1822 the General Society for the Encouragement of National Industry was formed at Brussels under a royal charter for 27 years, and which has since been extended to 1875. It has a social capital of 30,000,000 florins, divided into 60,000 shares of 500 florins, bearing interest at 5 per cent. The administrative body consists of a governor, nominated by the king, six directors, a secretary, and a treasurer. It discounts bills, receives money at interest, grants loans and advances on titles and other deposits, &c. The national bank, instituted by charter granted in 1850 for twenty-five years, has its seat at Brussels, and has branches in all the provincial capitals and several other towns. Its capital is 25,000,000 fr., in shares of 1000 fr. each. It pays a dividend of 5 per cent. upon the shares, and one-third at least of the profits, exceeding 6 per cent., goes to form a sinking fund. The administration consists of a governor nominated by the king, six directors, and a council of censors. The banking operations are superintended by a government commissary; a report upon its state is presented to the government every month. The state funds are deposited in this bank. The bank of Belgium, chartered in 1835 for twenty-five years, but which has been extended to 1875, has a capital of 30,000,000 fr. Its seat is at Brussels. The bank of Flanders is established in Ghent.

Weights, &c.

The weights and measures of Belgium are the same as those of France. Gold, silver, and copper coins are struck at the royal mint in Brussels. The gold coins are ten and twenty-five franc pieces; the silver are of the value of ¼, ½, 1, 2, and 2½ francs; and the copper of 1, 2, 5, and 10 centimes.

Belgium. Roads, &c.

After England, there is no country in Europe where, in proportion to its extent, the roads are more numerous or better kept than in Belgium. They are of three kinds—those maintained by the state, and those by the provinces and communes. The total length of the two latter cannot be given with accuracy; that of the first is 1247 leagues, or 3865 English miles. The length of the navigable rivers and canals has already been given; the income for the ten years preceding 1851 was 25,642,467 fr., and the expenditure 11,556,282 fr.

Railroads.

A bill was passed in 1834 authorizing the establishment of a system of railroads, of which Malines was to form the centre. One line extends eastward from Malines to the frontiers of Prussia, passing Louvain, Liège, and Verviers, another north to Antwerp, a third west to Ostend, passing Termonde, Ghent, and Bruges, and a fourth south to Brussels and the frontiers of France. Another bill in 1837 authorized a line from Ghent to the French frontiers and Tournay, passing Courtray and branches from Namur, Limbourg, and Luxembourg. The government railways are wrought on account of the government, and are under special administration. The line from Brussels to Malines was opened on 5th May 1835, and was the first railway in operation on the Continent. The total length of the various lines of railway in operation in the beginning of 1851 was 172 leagues of 5000 metres, or 535 English miles, as per following table:—

	Double Lines. Metres.	Single Lines. Metres.	Total. Metres.
Government.....	452,788	171,831	624,619
Conceded	94,943	141,835	236,778
	547,731	313,666	861,397

The amount expended by government in the construction of railways to the end of 1850 was 167,333,412 fr., or L.6,623,614. The expense of working these railways in 1850 was 9,195,315 fr., and the receipts 14,847,540 fr.

Postage.

In 1849 a system of postage was introduced into Belgium similar to that in this country. All letters not exceeding 10 grammes in weight (¼ oz.), destined for places not more than 30 kilometres (18 miles) distant, pay a postage of 10 centimes (1d.), and those to any greater distance within the kingdom 20 centimes. This postage increases with the weight.

Electric Telegraph.

The first electric telegraph, which was that between Brussels and Antwerp, was introduced into the country in 1846 by an English company. A law passed in 1850 has authorized the government to purchase this, as also to establish telegraphs on all the lines of railway.

For an account of the Belgian army and civic guard, see ARMY.

Finances.

The following table shows the annual income and expenditure for the seven years preceding 1851:—

	Income.	Expenditure.
1844	198,810,508 fr.	195,185,657 fr.
1845	129,855,951	134,389,349
1846	114,064,043	122,752,999
1847	113,528,063	127,572,374
1848	146,117,886	135,060,595
1849	113,871,437	112,267,069
1850	132,877,187	118,730,904

The excess of the expenditure over the revenue since the independence of Belgium to the end of 1850 is 16,129,896 fr.

The budgets for 1852 and 1853 are as under:—

	Revenue.			Expenditure.	
	1852.	1853.		1852.	1853.
Land-tax.....	18,359,750 fr.	18,359,750 fr.	Public debt...	36,713,397 fr.	38,119,299 fr.
Personal taxes	9,240,000	9,350,000	Pensions	3,497,922	3,365,922
Tax on patents.....	3,201,000	3,355,000	Ministry of Justice	12,853,454	11,981,558
Rent of mines.....	207,900	207,900	... Foreign Affairs	2,181,931	2,161,849
Custom duties	12,275,000	13,000,000	... Interior.....	7,599,861	6,859,555
Excise duties	20,470,000	23,220,000	... Public Works	16,695,400	17,018,088
Stamp duties	21,695,000	23,495,000	... War	26,787,000	39,937,000
Domains, forests, &c. ..	4,485,000	4,300,000	... Finances	11,626,114	11,241,945
Post-Office.....	3,200,000	3,400,000	Deficiencies & repayments	2,278,718	2,023,000
Railways, &c.	16,040,000	17,375,000	Railways and canals.....	26,708,000	... .
Packet-boats.....	200,000	200,000			
Arrears received	6,936,600	6,861,600			
	117,310,250	123,224,250		146,941,797	132,708,216

The public debt on 1st May 1853 amounted to 643,488,563 fr., of which the sum of 237,036,832 fr. was the share falling to Belgium of the public debt of the kingdom of the Netherlands.

(W. J.) (D. K.)

Belgorod || Believers.

BELGOROD, a city in the Russian government of Kursk, on the river Donetz. It is the seat of an archbishop, and has considerable linen and other manufactures, five churches, 1800 houses, and about 10,000 inhabitants. Long. 36. 40. E. Lat. 50. 55. N.

BELGRADE, a famous town and fortress of Servia, in European Turkey, situated near the confluence of the Save and Danube. The fortress stands on a steep eminence in the centre, and commands the Danube. It is inclosed with high walls, and possesses strong towers and a triple ditch, and is provided with mines and bomb-proof casemates. The principal mosque and the residence of the pasha of Servia are in this part of the town. The water-side division lies near the junction of the two rivers, on the north side, and is likewise well defended by walls and ditches. The Rascian town (so called from its inhabitants) is towards the west, in the direction of the Save; and the Palanka encircles the fortress on the south and east. The city is in many parts well built, but the streets are in general badly paved and filthy. Belgrade is a place of considerable strength, and is garrisoned by a large force. It is gradually losing its Oriental appearance, and assuming more of a European aspect. It has manufactures of arms, silk and cotton goods, carpets, and leather; and it is the principal entrepôt between Constantinople and Saloniki on the one hand, and between Vienna and Pesth on the other. This important town has sustained many sieges, and repeatedly passed from the hands of the Austrians to those of the Turks. It was taken by Solyman II. in 1522, and retaken by the Austrians in 1688, but again lost in 1690. In 1717 it surrendered to Prince Eugene. The imperialists retained it till 1739, when the Turks invested and reduced it. Austria again took it in 1789, but it was restored at the peace of 1791. And, lastly, in the year 1806, the Servian insurgents succeeded in carrying it. Pop. about 30,000, chiefly Servians. Long. 20. 36. E. Lat. 44. 48. N.

BELIAL, בליעל, a Hebrew word which signifies a wicked, worthless person, and is sometimes used to designate the Evil One, as in the sixth chapter of 2 Corinthians, where St Paul says, "What concord hath Christ with Belial?" The inhabitants of Gibeah, who abused the Levite's wife, have the name of Belial given them; and Hophni and Phineas, the sons of the high priest Eli, are called sons of Belial, on account of their crimes, and their unbecoming behaviour in the temple of the Lord.

BELIDOR, Bernard Forest de, a very eminent engineer, born in Catalonia in 1697. He was a brigadier-general in the French service, inspector-general of mines, and member of the academies of sciences at Paris and Berlin, and of the Royal Society of London. He died at Paris in 1761. His works on mathematics and military engineering are held in high estimation. Of these may be mentioned, *Cours de Mathématiques*, 1725, 4to; *La Science des Ingénieurs*, &c., Paris, 1729; *Le Bombardier Français*, Paris, 1731, 4to; *Traité des Fortifications*, Paris, 1735, 2 tom. 8vo; *Architecture Hydraulique*, Paris, 1737–53, 4 tom. 4to; *Dictionnaire Portatif de l'Ingénieur*, 1755, 8vo.

BELIEF, in a general sense, denotes a persuasion or assent of the mind to the truth of a proposition. In this sense, belief has no necessary relation to any particular kind of evidence. Thus we are said to believe our senses, to believe our reason, to believe a witness. But, in its more restricted and technical sense, belief, according to the schoolmen, denotes that kind of assent which is grounded on the authority or testimony of some person or persons asserting or attesting the truth of any matter whatsoever. In this sense it stands opposed to knowledge and science.

BELIEVERS, an appellation given towards the close of the first century to those Christians who had been admitted into the church by baptism. They were thus distinguished from catechumens, who had not been baptized, and consequently did not enjoy the privileges of believers.

Belion || Bell.

BELION, in *Ancient Geography*, a river of Lusitania; otherwise called *Limæa*, *Limius*, *Limia*, and *Lethe*, or the river of oblivion; now *El Lima*, in Portugal.

BELISARIUS, general of the Emperor Justinian's army, who overthrew the Persians in the East, the Vandals in Africa, the Goths in Italy, and, in a degenerate age, renewed the victories and triumphs which had immortalized the glorious times of the republic. But notwithstanding all his exploits, this great commander was falsely accused of a conspiracy against the emperor's life. The real conspirators had been detected and seized, with daggers hidden under their garments; and one of them died by his own hand, while the other was dragged from the sanctuary to which he had fled for refuge. Pressed by remorse, or tempted by the hopes of safety, the latter accused two officers of the household of Belisarius; and they, in the agony of torture, declared that they had acted according to the secret instructions of their patron. But posterity will not hastily believe that a hero who in the vigour of life had disdained the fairest offers of ambition and revenge, should stoop to the murder of his prince, whom he could not expect long to survive. His followers were impatient to fly; but flight must have been supported by rebellion, and he had lived enough for nature and for glory. Belisarius appeared before the council with less of fear than of indignation; after forty years' service the emperor prejudged his case; and injustice was sanctified by the presence and authority of the patriarch. The life of the venerable veteran was indeed spared; but his fortunes were sequestrated, and for the space of a year he was kept a close prisoner in his own palace. At length his innocence was acknowledged, and his freedom and honours were restored; but death, which might have been hastened by grief and resentment, removed him from the world about eight months after his deliverance, A.D. 565. That he was deprived of his sight, and reduced to beg charity in the streets of Constantinople, uttering the doleful solicitation of *Date obolum Belisario*, "give a penny to Belisarius," is a fiction of later times, which has obtained credit as a supposed instance of extreme vicissitude of fortune. This idle fable seems to have been derived from a work of the twelfth century, entitled the *Chiliads*, by John Tzetzes, a monk, who relates the blindness and beggary of Belisarius in ten doggerel verses (*Chiliad* iii. No. 88, 339–348, in *Corp. Poet. Græc.* tom. ii. p. 311). The tale seems to have been imported into Italy with the language and manuscripts of Greece; repeated before the end of the fifteenth century by Crinitus, Pontanus, and Volaterranus; attacked by Alciatus for the honour of the law, and defended by Baronius for the honour of the church. Yet Tzetzes, the father of the fabrication, had confessedly read in the chronicles that Belisarius did not lose his sight, and that he recovered his fortune and his fame. (See the works of Procopius, and the *Life of Belisarius* by Lord Mahon.)

BELL, a well-known instrument, ranked by musicians among the musical instruments of percussion.

Bell-metal is an alloy of copper and tin, usually in the proportion of 80 parts of copper to 20 parts of tin. Zinc generally enters into the composition of small shrill bells. By analysis Dr Thompson found an English bell-metal to consist of 800 parts copper, 101 tin, 56 zinc, and 43 lead. The thickness of a bell's edge is usually 1-15th of the diameter, and its height is twelve times its thickness. The bell-founders have a diapason, or scale, wherewith they measure the size, thickness, weight, and tone of their bells.

The sound of a bell is produced by the vibratory motion of its parts, somewhat like that of a musical chord. The stroke of the clapper must necessarily change the figure of the bell, and from a circle convert it into an oval or ellipse; but the metal having a great degree of elasticity, that part

Bell. impinged on by the clapper, and driven farthest from the centre, will return, and even incline nearer the centre than before; so that the two parts which were extremes of the longest diameter become in turn those of the shortest; and thus the external surface of the bell undergoes alternate changes of figure, and by this means gives that tremulous motion to the air in which the sound consists. M. Perrault maintains that the sound of the same bell or chord is a compound of the sounds of its several composite parts; so that where the parts are homogeneous, and the dimensions of the figure uniform, there is such a perfect mixture of all these sounds as constitutes one uniform, smooth, even sound; while the contrary circumstances produce harshness. This he proves from bells differing in tone according to the part impinged on, although there is a motion of all the parts wherever the blow happens to be given. He therefore considers bells as a compound of an infinite number of rings, which, according to their different dimensions, have different tones, as chords of different lengths have; and when struck, the vibrations of the parts immediately impinged determine the tone, being supported by a sufficient number of consonant tones in the other parts.

Bells are heard at a greater distance when placed on plains than on hills, and still farther in valleys than on plains; the reason of which seems to be, that the higher the sonorous body the rarer is the medium, and, consequently, the less impulse it receives, and the less proper a vehicle it is to convey sound to a distance.

M. Reaumur, speaking of the shape most proper for bells, remarks, that as pots and other vessels more immediately necessary to the service of life were doubtless made before bells, it probably happened that the observing these vessels to have a sound when struck, gave occasion to making bells in that form; but that it does not appear that this is the most eligible figure: for lead, which in its ordinary state has no sonorous property, yet when cast in a melting ladle or otherwise into a segment of a sphere, acquires a certain degree of sonorousness; and hence he infers that such a figure is peculiarly adapted for small bells, such as those of house-clocks, &c.

The use of bells was very ancient. We find them among Jews, Greeks, Romans, Christians, and heathens, variously applied, as on the necks of men, birds, oxen, horses, and sheep. It is remarkable, however, that there is no appearance of bells in any of the Egyptian monuments. Bells were chiefly suspended in buildings, either religious, as in churches, temples, and monasteries; or civil, as in houses, markets, baths; or military, as in camps and frontier towns. In the museum at Naples are several kinds of ancient bells, one of which is a simple disk of metal.

Among the Jews it was ordained that the lower part of the blue tunic which the high priest wore when he performed religious ceremonies should be adorned with pomegranates and gold bells, intermixed alternately and at equal distances. (Exodus xxviii. 33, 34.) The number of the bells worn by the high priest is not specified; but the sacred historian has intimated the purpose they were intended to serve, viz., to give intimation both when he entered and came out of the holy place. The tinkling of a bell at the elevation of the host in the Roman Catholic sacrament of the mass is founded upon this circumstance.

Among the Greeks, those who went the nightly rounds in camps or garrisons, carried with them little bells, which they rung at each sentry-box, to see that the soldiers on watch were awake. A codonophorus or bellman also walked in funeral processions, some space in advance of the corpse, not only to keep off the crowd, but to advertise the *flamen dialis* to keep out of the way, lest he should be polluted by the sight, or by the funerary music. The priest of Proserpine at Athens, called *hierophantes*, rung a bell to call the people to sacrifice. There were also bells in the houses of great men, to call up the servants in the morning. Zonaras informs us that bells were suspended along with whips on the triumphal chariots of victorious generals, in order to put them in mind that they were still liable to public justice. Bells were also put on the necks of criminals going to execution, that persons might be warned by the noise to avoid so ill an omen as the sight of the hangman or the condemned criminal, who was devoted to the *dii manes*. Bell.

Of bells on the necks of brutes, express mention is made in Phædrus; and taking them away was construed theft by the civil law.

With respect to the origin of *church-bells*, Mr Whitaker observes, that as bells were used by the Romans to signify the times of bathing, they were naturally applied by the Christians of Italy to denote the hours of devotion, and to summon the people to church. The first application of them to this purpose is ascribed by Polydore Virgil and others to Paulinus, bishop of Nola, a city of Campania, about A.D. 400. Hence, it is said, the names *nolæ* and *campanæ* were given them; the one referring to the city, the other to the country. In Britain, bells were applied to church purposes before the conclusion of the seventh century in the monastic societies of Northumbria, and even as early as the sixth in those of Caledonia. They were therefore used from the first erection of parish churches. Those of France and England appear to have been furnished with several bells. In France they were sometimes composed of iron; and in England, as formerly at Rome, they were frequently made of brass.

Ingulphus mentions that Turketulus, abbot of Croyland, who died about A.D. 870, gave to the church of that abbey a great bell, which he named *Guthlac*, and afterwards six others, two of which he called *Bartholomew* and *Bettelin*, two *Turketul* and *Tatwin*, and two he named *Pega* and *Bega*. All of them rang together; and the same author says, *Non erat tunc tanta consonantia campanarum in tota Anglia*. Not long after, Kinseus, archbishop of York, gave two great bells to the church of St John at Beverley, and at the same time provided that other churches in his diocese should be furnished with bells. Mention is also made by St Aldhelm, and William of Malmesbury, of bells given by St Dunstan to the churches in the West. The number of bells in every church gave occasion to the curious and singular architecture which is often found in the campanile or bell-tower; an addition which is perhaps more susceptible of architectural embellishment than any other part of the edifice. It was the constant appendage of every parish church belonging to the Saxons, and is distinctly mentioned as such in the laws of Athelstane.

The Greek Christians are usually said to have been unacquainted with bells till the ninth century, when the construction of these instruments was first taught them by a Venetian; but it is not true that the use of bells was entirely unknown in the ancient Eastern churches, and that they called the people to church with wooden mallets. In some learned dissertations on the Greek temples, Leo Allatius proves the contrary from several ancient writers. In his opinion bells first began to be disused after the taking of Constantinople by the Turks; the latter, it seems, having prohibited them lest their sound should disturb the repose of souls wandering in the air. Father Simon, however, thinks that the Turks prohibited the Christians the use of bells from political rather than religious motives; inasmuch as the ringing of bells might serve as a signal for revolts or popular commotions.

In the ancient monasteries we find six kinds of bells enumerated by Durandus, namely, *squilla*, rung in the refectory; *cymbalum*, in the cloister; *nola*, in the choir; *nolula* or *dupla*, in the clock; *campana*, in the steeple; and *signum*, in the tower. Belethus very nearly agrees with Durandus, only for *squilla* he puts *tintinnabulum*, and places the *campana* in the tower, and *campanella* in the cloister.

Bell. Others place the *tintinnabulum* or *tinniolum* in the refectory or dormitory; and add another bell, called *corrigiuncula*, rung at the time of giving discipline, to call the monks to be scourged. The *cymbalum* is said to have been rung in the cloister, to call the monks to meals.

From the researches of a writer who has paid particular attention to this subject, we learn that bells frequently bore such inscriptions as the following:

Funera plango, Fulgura frango, Sabatta pango,
Excito lentos, Dissipo ventos, Paco cruentos.

In the little sanctuary at Westminster, King Edward III. erected a clocher, and placed in it bells for the use of St Stephen's chapel, round the largest of which were cast in the metal these words:

King Edward made mee thirtie thousand weight and three.
Take me down and wey mee, and more you shall fynd mee.

But these bells having been ordered to be taken down in the reign of Henry VIII., some one wrote underneath with a coal:

But Henry the eight
Will bait me of my weight.

This last distich alludes to a fact mentioned by Stowe in his Survey of London, that near to St Paul's school stood a clocher in which were four bells called *Jesus's Bells*, the greatest in all England, against which Sir Miles Partridge staked a hundred pounds, and won them of King Henry VIII. at a cast of dice. Nevertheless, in foreign countries there were bells of greater magnitude. In the steeple of the great church at Rouen, in Normandy, was a bell with this inscription:

Je suis George d'Ambois,
Qui trente cinque mille pois.
Mais lui qui me pesera
Trente six mille me trouvera.

But it was probably destroyed when the greater part of the magnificent edifice containing it was consumed by fire. It is a common tradition that the bells of King's College chapel, in the university of Cambridge, were brought by Henry V. from some church in France soon after the battle of Agincourt. They were taken down and were afterwards sold to a bell-founder in Whitechapel, who melted them down.

The various uses of bells have been summed up in the following old distich:

Laudo Deum verum, plebem voco, congrego clerum,
Defunctos ploro, pestem fugo, festa decoro.

Matthew Paris observes, that anciently the use of bells was prohibited in time of mourning; at present, however, the tolling of them forms one of the principal ceremonies of interment. Mabillon adds, that it was an ancient custom to ring bells for persons about to expire, to advertise the people to pray for them. The passing bell, indeed, was anciently rung for two purposes; one, to bespeak the prayers of all good Christians for a soul just departing; the other, to drive away the evil spirits who were supposed to stand near the bed of the dying, or about the house, ready to seize their prey, or at least to molest and terrify the soul in its passage. By the ringing of the bell,—for Durandus informs us that evil spirits are greatly afraid of bells,—they were kept aloof; and the soul, like a hunted hare, gained the start, or had what is by sportsmen called *law*. This dislike of spirits to bells is mentioned in the *Golden Legend* by Wynkyn de Worde. "It is said, the evil spirytes that ben in the regyon of thayre, doubte moche when they here the belles rongen: and this is the cause why the belles ben rongen when it thondreth, and whan grete tempeste and outrages of wether happen, to the ende that the feinds and wycked spirytes shold be abashed and flee, and cease of the movynge of tempeste." Lobineau observes, that the custom of ringing bells at the approach of thunder is of some antiquity; but that the design was not so much to shake the air, and so dissipate the thunder, as to call the people to church to pray that the parish might be preserved from that terrible meteor. Bell.

In Roman Catholic times bells were baptized and anointed *oleo chrismatis;* they were also exorcised and blessed by the bishop, from a belief that, when these ceremonies were performed, they had power to drive the devil out of the air, to calm tempests, to extinguish fires, aad to recreate even the dead. The ritual for these ceremonies is contained in the Roman pontifical; and it is still usual in such baptisms to give to bells the name of some saint. In Chauncy's *History of Hertfordshire* there is a relation of the baptism of a set of bells in Italy, which was performed with great ceremony a short time before that book was written. The bells of the parish church of Winnington, in Bedfordshire, had each its name cast about the verge, with these rhyming hexameters:

Nomina Campanis hæc indita sunt quoque nostris.
1. Hoc signum Petri pulsatur nomine Christi.
2. Nomen Magdalene campana sonat melode.
3. Sit nomen Domini benedictum semper in eum.
4. Musa Raphaelis sonat auribus Immanuelis.
5. Sum Rosa pulsata mundique Maria vocata.

By an old chartulary, it appears that the bells of the priory of Little Dunmow, in Essex, were, in the year 1501, newcast, and baptized by the following names:

Prima in honore Sancti Michaelis Archangeli.
Secunda in honore S. Johannis Evangelisti.
Tertia in honore S. Johannis Baptisti.
Quarta in honore Assumptionis beatæ Mariæ.
Quinta in honore sanctæ Trinitatis, et omnium sanctorum.

The bells of Osney Abbey, near Oxford, which were very famous, had the respective names of Douce, Clement, Austin, Hautecter, or rather Hautcleri, Gabriel, and John.

Nankin, in China, was anciently celebrated for the largeness of its bells. But their enormous weight brought down the tower which contained them. One of these bells was nearly twelve English feet in height, seven and a half in diameter, and twenty-three in circumference, its figure cylindric, except a swelling in the middle, and the thickness of the metal about the edges, seven inches. From the dimensions, its weight was computed at 50,000 pounds. These bells were cast about four centuries ago. They were designated the hanger (*tchoui*), the eater (*che*), the sleeper (*choui*), the will (*fi*). Father le Comte adds, that there are seven other bells in Pekin cast in the reign of Youlo, each of which weighs 120,000 pounds. But the sound of even the largest Chinese bell is very poor, owing to the circumstance of its being struck with a clapper of wood, instead of iron. The bells of China, however, are far exceeded by those of Moscow. One presented by Czar Beris Godunof to the cathedral weighs 288,000 pounds, and the great bell of Moscow cast in 1653 by order of the Empress Anne, and still remaining on the ground, is computed to weigh 443,772 pounds. It is 19 feet high, and has a marginal circumference of 63 feet 11 inches English. In England the heaviest bell is that made for York Minster in 1845, which weighs 27,000 pounds, but is not more than 7 feet 7 inches in diameter. The Great Tom of Oxford weighs 17,000 pounds; the Great Tom of Lincoln weighs 12,000 pounds; the great bell of St Paul's in London is 11,500 pounds, and has a diameter of 9 feet, or more than 28 feet in circumference.

The practice of ringing bells in change, or regular peals, is said to be peculiar to England. The custom seems to have commenced in the time of the Saxons, and to have been common before the Conquest. The *tolling* of a bell is nothing more than the production of sound by a stroke of the clapper against the side of the bell, the bell itself being in a pendent position and at rest. But in *ringing*, the bell is elevated to a horizontal position, so that, by means of a wheel and a rope, the clapper strikes forcibly on one side as it ascends, and on the other side in its return downwards, pro-

Bell. ducing at each stroke a sound. In England the ringing of bells is reduced to a system, and peals have been composed which bear the names of the inventor.

Electrical BELLS are used in a variety of entertaining experiments by electricians. The apparatus, which is originally of German invention, consists of three small bells suspended from a narrow plate of metal, the two outermost by chains, and that in the middle, from which a chain passes to the floor, by a silken string. Two small knobs of brass are also suspended by silken strings, one on each side of the bell in the middle, which serve for clappers. When this apparatus is connected with an electrified conductor, the outermost bells suspended by the chains will be charged, attract the clappers, and be struck by them. The clappers, becoming electrified, will likewise be repelled by these bells, and attracted by the middle bell, and discharge themselves upon it by means of the chain extending to the floor. After this they will be again attracted by the outermost bells, and thus, by striking the bells alternately, occasion a ringing, which may be continued at pleasure. Flashes of light will be seen in the dark between the bells and clappers, and if the electrification be strong, the discharge will be made without actual contact, and the ringing will cease.

BELL, *Andrew, D.D.*, a clergyman of the English Church, who is well known for his philanthrophic efforts in the cause of education, and more particularly for his success in extending the monitorial system of instruction in schools. He was the projector and founder of those admirable institutions called national schools; and the author of *An Experiment in Education at the Male Asylum, Madras;* and of *Instructions for conducting Schools on the Madras system*, &c., &c. Dr Bell was born at St Andrews in 1753, and received his education in the university there. Some of his early years were spent in America; and he was afterwards chaplain to Fort St George, and minister of St Mary's at Madras. During his residence in the East Indies he acquired considerable property; which, together with some lucrative preferments in England, enabled him to bequeath no less than L.120,000 in support of national institutions and public charities. This benevolent man died at Cheltenham in 1832, and his remains were interred in Westminster Abbey.

To the liberality of Dr Bell St Andrews is indebted for the foundation of Madras College.

BELL, *Benjamin*, an eminent surgeon, born at Dumfries in 1749. He studied at Edinburgh under the celebrated Monro, and combined with the office of head surgeon to the Edinburgh Infirmary an extensive practice in that city. He was the author of several standard works on surgery, among which may be noticed, *A Treatise on Ulcers*, and *A System of Surgery*. He died in 1806.

BELL, *Sir Charles, K.H.*, an eminent anatomist, physiologist, and surgeon, son of the Rev. William Bell, a clergyman of the Episcopal Church of Scotland, was born at Edinburgh in November 1774. Having studied at the High School and university of that city, he devoted himself at an early age to the study of anatomy, under his brother Mr John Bell, who was twelve years older, and who had already laid the foundation of his fame as an anatomist and a surgeon. Under the guidance of this enlightened teacher, Charles Bell soon gave evidence of the talents which seem to have been inherited by every member of his family. While yet a pupil, he published the first volume of his *System of Dissections*, illustrated by engravings from his own drawings. On the 1st August 1799, he was admitted a member of the College of Surgeons, and consequently became one of the surgeons of the Royal Infirmary; for all the members of that college were then in rotation surgeons of the hospital. His knowledge of anatomy, and the admirable use of his hands, exhibited both in his dissections and his drawings, were already conspicuous; and his operations were distinguished by their dexterity and simplicity. He eagerly availed himself of the opportunities afforded by his attendance in the infirmary to improve his knowledge of pathology, and, with that view, invented a method of representing morbid parts in models, some of which are still preserved in the museum of the Royal College of Surgeons of Edinburgh. About this time a controversy arose respecting the medical attendance in the Royal Infirmary, which terminated in the exclusion of several of the surgeons, amongst whom was Charles Bell. In 1804 he offered to pay L.100 a-year, and to transfer for the use of the students the museum he had collected, on condition that he should be "allowed to stand by the bodies when dissected in the theatre of the infirmary, and to make notes and drawings of the diseased appearances;" but this proposal was rejected. In 1806 he removed to London, where he immediately commenced a course of lectures on anatomy and surgery, and rapidly rose to distinction. Bell.

Previous to his departure from Edinburgh he had written his work on the *Anatomy of Expression*, which was published shortly after his arrival in London, and immediately attracted attention. Both as an artist and as a physiologist he had felt the want of some philosophical explanation of the rationale of expression; of those muscular movements which are the natural external indications of the passions and emotions of the mind; and perhaps no other man was so well qualified to supply the deficiency. But he did not confine himself to the illustration of what is useful to the artist; he also explained how an acquaintance with the anatomy of expression might be available to the surgeon or the physician in distinguishing the nature and extent of some important diseases. Independent of its intrinsic merit, this work has another interest; for there is reason to believe that his inquiries into the functions of the nerves in connection with the anatomy of expression led him to prosecute those investigations which terminated in the most remarkable anatomical discovery of our time.

In the same manner as it had been taught before the discoveries of Harvey, that there was a flux and reflux of the blood in the arteries and veins, so it was taught, before the discoveries of Bell, that the same nerves transmitted the mandate of the will *from* the sensorium to the organs of voluntary motion, and likewise carried *to* the sensorium intelligence of the condition of their extremities or sensation; and that, in some mysterious manner, these two impulses might be simultaneously communicated along the same chord in opposite directions, without impairing the efficiency of either. This doctrine, which now appears to be startling, continued to be taught, or was left to be inferred, by every anatomical teacher in Europe for at least a year after Sir Charles Bell had announced—in letters still extant, and bearing the London and Edinburgh post-marks of the 5th and 8th December 1807—his ideas on the nervous system. To him we owe the discovery that no one nerve serves the double purpose of ministering both to motion and to sensation;—that the spinal nerves and the fifth nerve of the brain, which had been regarded each as one nerve, consisted each of two distinct nerves connected with different portions of the brain, inclosed in one sheath for the convenience of distribution, but performing different functions in the animal economy, corresponding with the different portions of the brain to which they could be traced—the one conveying the mandates of the will *from* the sensorium, the other conveying *to* the sensorium intelligence of the condition of distant parts or sensation;—that, as the arteries carry the blood from the heart, and the veins carry it to the heart, so one set of nerves carries the impulses of volition from the brain, and another carries the impulses of sensation to the brain;—that the brain is divided, together with the spinal marrow which is prolonged from it, into separate parts, ministering respectively to the distinct functions of motion and sensation;—and that the

Bell. origin of the nerves from one or other of these sources seems to endow them with the particular property of the division whence they spring. Such were the leading features of Bell's great discovery, the greatest in the physiology of the nervous system for twenty centuries, and one of the most remarkable that the history of anatomy has to record.

For this discovery the Royal Society of London awarded him the first annual medal given by George IV. in 1829; and when a new order of knighthood was instituted on the accession of the late king to the throne, Bell was amongst the first who were invested. This was the only public reward he received, and he had merited it by the services he rendered to the wounded after the battles of Corunna and Waterloo, if he had never rendered any other. On both of these occasions he had proceeded to the scene of action, relinquishing for the time his professional avocations in London.

Of his various writings on the practice of different branches of his profession, it is sufficient to say that they place him in the highest class of our writers on surgery. But there is another series of his works, which, of all his labours, afforded him the greatest pleasure. In his treatise on animal mechanics, written by desire of the Society for Propagating Useful Knowledge, he embodied the substance of some of his lectures on the evidences of design to be found in the anatomy of the human body, which had attracted admiring crowds to the College of Surgeons. These views had been deeply impressed upon his mind, and the success with which he illustrated them probably pointed him out to the executors of the late Earl of Bridgewater as a fit person to maintain a part in that great argument which it was the purpose of that nobleman's bequest to have published. Sir Charles's contribution was the admirable treatise on the Hand. Still following out this favourite subject of his contemplation, he associated himself with Lord Brougham in the illustration of Dr Paley's *Natural Theology*, published in 1836, and contributed some of the most interesting of these illustrations.

This most estimable and distinguished man died suddenly on the 29th April 1842, at Hollow Park, in Worcestershire. (J. M—LL.)

Bell, *George Joseph*, brother of the preceding, was born at Edinburgh on the 20th of March 1770. At the age of eight he entered the High School, but he received no university education further than attending Tytler's lectures on civil history, Stewart's course of moral philosophy, and Hume's lectures on the law of Scotland. He became a member of the Faculty of Advocates in 1791, and was one of the earliest and most attached friends of Francis Jeffrey. It was by his counsel and encouragement that the distinguished critic was persuaded to persevere in his professional career at a time when his prospects of success at the bar were dark and discouraging. In 1804 he published a *Treatise on the Law of Bankruptcy in Scotland*, in 2 vols. 8vo, which was gradually enlarged in future editions, till at length a fifth edition was published in 1826, in 2 vols. 4to, under the title of *Commentaries on the Law of Scotland and on the Principles of Mercantile Jurisprudence*—an institutional work of the very highest excellence, which has guided the judicial deliberations of his own country till the present time, and has had its value acknowledged by no less jurists than Story and Kent. In 1821 he was unanimously elected professor of law in the university of Edinburgh; and in 1831 he was appointed to one of the principal clerkships in the Supreme Court. He was in 1833 placed at the head of a commission to inquire into the expediency of making various improvements in the Scottish bankruptcy law; and in consequence of the reports of the commissioners, chiefly drawn up by himself, many beneficial alterations have been made in this department of the law. He died at Hull on the 23d September 1843.

Bell, *Henry*, an ingenious mechanic, well known for his successful application of steam-power to the propulsion of ships, was born at Torphichen in Linlithgowshire, in 1767. Having received the ordinary education of a parish school, he was apprenticed to his uncle, a mill-wright; and, after qualifying himself as a ship-modeller at Borrowstownness, went to London, where he found employment under Rennie, the celebrated engineer. Returning to Scotland in 1790, he first settled as a carpenter at Glasgow, and afterwards removed to Helensburgh, on the Firth of Clyde, where his wife superintended a large inn, together with the public baths, while he pursued his mechanical projects, and also found occasional employment as an engineer. It was not until January 1812 that he gave a practical solution of the difficulties which had beset all previous experimenters, by producing a steamboat of about twenty-five tons, propelled by an engine of three-horse power, at a speed of seven miles an hour. A particular account of this vessel, which he named the "Comet," as well as of the experiments of his predecessors in the same line, will be found under the head Steam Navigation. It will there be seen that, although the honour of priority, by about four years, is admitted to belong to Robert Fulton, an American engineer, it appears to admit of no doubt that Fulton had received very material assistance in the construction of his vessel from Bell and others in this country. The latter days of this ingenious man were rendered comfortable by a handsome sum subscribed for him among the citizens of Glasgow; and he also received from the trustees of the river Clyde a pension of L.100 a-year. He died at Helensburgh, November 14. 1830.

Bell, *John*, of Antermony, a Scottish traveller in the first half of the last century. He was born in 1691, and was educated for the medical profession, in which he took the degree of M.D. In 1714 he set out for St Petersburg, where, through the introduction of a countryman, he was nominated medical attendant to Valensky, recently appointed to the Persian embassy, with whom he travelled from 1715 to 1722, through Russia, Turkey, Persia, and China. He had scarcely rested from this last journey, when he was summoned to attend Peter the Great in his perilous expedition to Derbend and the Caspian Gates. The narrative of this journey he has enriched with interesting particulars of the public and private life of that remarkable prince. In 1738 he was sent by the Russian government on a mission to Constantinople, to which, accompanied by a single attendant who spoke Turkish, he proceeded in the midst of winter, and all the horrors of a barbarous warfare; and in May 1738 he returned to St Petersburg. It appears that after this he was several years established as a merchant at Constantinople, where he married in 1746. In the following year he retired to his estate of Antermony in Scotland, where he lived in ease and affluence, beloved by his neighbours and respected by all who knew him. He died in 1780.

His travels, published at Glasgow, in 2 vols. 4to, 1763, were speedily translated into French, and widely circulated in Europe. (T. S. T.)

Bell, *John*, an eminent anatomist and surgeon, was born at Edinburgh May 12. 1763. He had the merit of being the first in Scotland who applied with success the science of anatomy to practical surgery. While still a young man, he established, in the face of much opposition, an anatomical theatre in Surgeon Square, where he attracted large audiences by his admirable lectures on anatomy, physiology, and surgery, in which he was assisted by his younger brother Charles. After his exclusion from the infirmary (to which reference has been made in the notice of Sir Charles Bell), Mr Bell ceased to lecture, and devoted his time to study and practice. He died at Rome in 1820, while on a tour in Italy for the benefit of his health. To great skill in his profession he united high and varied mental abilities and extensive learning. His principal works are the following:—*Anatomy of the Human Body*, 3 vols. 8vo, 1793–1802; *Discourses on the Nature and Cure of Wounds*,

Bell || Bellarmino.

2 vols. 8vo, 1793–95; *Principles of Surgery*, 3 vols. 8vo, 1801; and several volumes of Engravings illustrative of the Human Anatomy. His *Observations on Italy* were published by his widow in 1825.

BELL ROCK LIGHTHOUSE. See LIGHTHOUSES.

BELL'S REAPING MACHINE. See AGRICULTURE.

BELLA, STEFANO DE LA, an eminent engraver, born at Florence A.D. 1610. He was apprenticed to a goldsmith; but some prints of Callot having accidentally fallen into his hands, he was seized with a passion for engraving; and studied the art under Canta Gallina, who had also been the instructor of Callot. De la Bella at first imitated the manner of Callot: but afterwards adopted one entirely his own, which in freedom and spirit is said even to have surpassed that of his fellow-disciple. In 1642 he went to Paris, where Cardinal Richelieu engaged him to go to Arras and make drawings of the siege and taking of that town by the royal army. After residing a considerable time at Paris, he returned to Florence, where he obtained a pension from the grand duke, whose son, Prince Cosmo, he instructed in the art of design. He died in 1664.

BELLAGGIO, a town in Lombardy, at the point where the lake of Como is separated from the lake of Lecco. It is well built, and surrounded by most picturesque scenery.

BELLAI, or BELLAY, *Guillaume du*, lord of Langey, a French general, who signalized himself in the service of Francis I. His great abilities as a negotiator occasioned the remark of the Emperor Charles V., that "Langey's pen had fought more against him than all the lances in France." He was sent as viceroy into Piedmont, where he took several towns from the imperialists. His address in penetrating into the most secret designs of the enemy was extraordinary; and he spared no expense for that end. He was extremely active in influencing some of the universities of France to give a judgment agreeable to the desires of Henry VIII., when that prince wished to divorce his queen in order to marry Anne Boleyn. Langey composed several works, the most remarkable of which was the history of his own times. He died in 1543, and was buried in the church of Mans, where a noble monument was erected to his memory.

BELLANO, a town of Lombardy, situated at the end of the vale where the Pioverna forms a magnificent cataract, on the east side of the lake of Como. It is a place of considerable trade, with many country seats in the vicinity.

BELLARMINO, ROBERTO (*Cardinal Bellarmin*), the most eminent of Romish doctrinal controversialists, was born October 4. 1542, at Montepulciano, in Tuscany. At the age of eighteen he enrolled himself among the Jesuits, and was appointed by that society to teach theology at Louvain. The fame of his preaching in that town is said to have attracted even Protestants from England and Holland to hear him. After a residence of seven years in the Low Countries, he returned to Italy, and was appointed by Gregory XIII. to deliver controversial lectures in the college founded by that pontiff. Bellarmin, in the capacity of divine, accompanied the legation sent into France in 1590 by Sixtus V. Eight years afterwards, Clement VIII. made him a cardinal, which dignity he is said to have accepted with extreme reluctance. In 1601 he was appointed to the archbishopric of Capua; but he resigned that office on being made librarian of the Vatican by Paul V., and devoted himself, till the time of his death, to the affairs of the court of Rome. It has been said that the circumstance of his being a Jesuit was the sole cause of his exclusion from the papacy on the demise of Leo XI. and of Paul V. Bellarmin died at Rome, September 17. 1621. It is certain that no Jesuit ever did greater honour to his order, and that no author ever defended the cause of the Romish church in general, and that of the pope in particular, with greater ingenuity and skill. The Protestants have owned this sufficiently; for during the space of fifty years there was scarcely any divine of note among them who did not fix upon Bellarmin as the subject of his books of controversy. But notwithstanding the zeal with which Bellarmin maintained the power of the pope over the temporality of kings, he displeased Sixtus V. in his work *De Romano Pontifice*, by not insisting that the power which Jesus Christ gave to his vicegerent was direct, instead of indirect; and he had the mortification to see it put into the Index of the Inquisition, though it was afterwards removed. At his death he left to the Virgin Mary one half of his soul, and to Jesus Christ the other. Bellarmin is said to have been a man of great chastity and temperance, and remarkable for his patience. His stature was low, and his mien ungainly; but his countenance was expressive of genius. His style, though not pure, is perspicuous; and the words which he first made use of to express his thoughts were generally so suitable, that few erasures appeared in his writings. Cardinal Bellarmin was the author of numerous works, the principal of which are the following: *Disputationes de Controversiis Christianæ Fidei*, &c.; *Institutiones Hebraicæ linguæ; Explanatio in Psalmos; De Scriptoribus Ecclesiasticis; De Editione Latinâ Vulgatâ; De Officiis Episcoporum; Doctrina Christiana; De Ascensione Mentis in Deum per scalas Rerum Creatarum; De Arte Bene Moriendi; De gemitu Columbæ.*

Bellaspoor || Bellenden.

BELLASPOOR, a town of Northern India, on the left bank of the Sutlej, which is here 100 yards broad when the water is lowest. Its elevation is 1465 feet above the level of the sea, and the situation is exceedingly picturesque.

Mr Forster, who visited the place in 1783, found the houses well and regularly built of stone and mortar, and the streets all paved, though roughly; but in 1820, according to Moorcroft, the town was in a ruinous condition from having been twice plundered by the Ghoorkas. The traveller last mentioned effected the passage of the river in the vicinity of Bellaspoor, by means of the *mussuk* or float composed of inflated skins. His party consisted of 300 persons, with sixteen horses and mules, and 150 tons of baggage and merchandise. Thirty watermen, each managing a skin, conveyed the whole across in about an hour and a half. Bellaspoor is the chief place of the hill state of Kuhloor, and the residence of the rajah. Long. 76. 50. Lat. 31. 19. (E. T.)

BELLEAU, REMI, a French poet, born at Nogent-le-Rotrou, in 1528. He lived in the family of René of Lorraine, Marquis of Elbeuf, and attended him in his expedition into Italy in 1557. Belleau was one of the seven poets or his time who were denominated the *French Pleiades*. He died at Paris in 1577. His works were published at Paris in 1578 in 2 vols. 12mo.

BELLEGARDE, a barrier fortress of France, stands on one of the Eastern Pyrenees, in Long. 2. 50. E. Lat. 42. 27. N.

BELLE-ISLE, an island on the coast of France, in the arrondissement of L'Orient and department of Morbihan. Its extent is about 75 square miles; and it contains three towns and a number of villages, with 9000 inhabitants.

BELLE-ISLE, an island of North America, at the mouth of the strait of the same name, between New Britain and the north end of Newfoundland. It is 21 miles in circumference, and 16 miles from the coast of Labrador. Long. 55. 20. W. Lat. 52. 5. N.

BELLENDEN, JOHN, archdeacon of Moray, occupies a conspicuous place in the literary annals of Scotland, but his personal history is still involved in some degree of obscurity. Several writers have confounded him with Sir John Bellenden of Auchinoul; an error founded only on the identity of their names, as the judge appears to have survived the archdeacon for twenty-seven years. Bellenden was probably educated in the university of St Andrews. Bale refers his birth to the eastern part of the kingdom, probably Haddington or Berwick. His education is represented as uncommonly liberal; and as he took the degree of D.D. in the university of Paris, his

Bellenden, John.

course of academical study must have been very complete.[1] Dr Campbell has remarked that his phraseology occasionally savours of a French education:[2] it must however be recollected, that the poets of this age were too generally disposed to adopt terms of a French as well as Latin origin; and that the practice cannot be considered as peculiar to those who had been educated in France. Sir David Lindsay, in a poem supposed to have been written in the year 1530, mentions him in the following terms:

Bot now of late is starte up hastelie,
Ane cunnyng clark quhilk wrytith craftelie,
Ane plant of poetis callit Ballendyne,
Quhose ornat warkis my wit can nocht defyne:
Get he into the courte auctoritie,
He will precell Quintyn and Kenedie.[3]

The literary merit of Bellenden does not seem to have been disregarded by the court; but he experienced the precarious fortune which so frequently attends courtiers. For this information we are partly indebted to his poem entitled the Proheme of the Cosmographe:

And fyrst occurrit to my remembring,
How that I wes in seruice with the kyng,
Put to his grace in zeris tenderest,
Clerk of his comptis, thoucht I wes inding,
With hart and hand, and euery othir thing
That mycht hym pleis in ony maner best,
Quhill hie inuy me from his seruice kest,
Be thaym that had the court in gouerning,
As bird but plumes heryit of the nest.

In the epistle subjoined to his translation of Boyce's history, he likewise states that he had been in the service of the king from his majesty's early infancy. It has been conjectured that he was employed in superintending the young monarch's education: but he makes no allusion to such an appointment, of which it would have been very natural to remind the king, if they had ever stood in the relation of tutor and pupil; and he very clearly informs us that his place in the royal household was that of clerk of accompts. James's preceptor was Gavin Dunbar, afterwards promoted to the archbishopric of Glasgow. Being dismissed from the king's service, as he states in the verses last quoted, Bellenden is supposed to have entered into that of Archibald earl of Angus, because a person of the same name was the earl's secretary in the year 1528. In the course of that year, Angus and some of his relations were accused of treason: John Ballentyne, who is described as his secretary, presented himself at the bar of the parliament on the 4th of September, and delivered a written protest in the name of the earl of Angus, his brother George Douglas, and his uncle Archibald Douglas of Kilspindie, stating the reasons why they ought not to be compelled to answer to the charge of treason which had been preferred against them; and in the afternoon of the same day, the secretary again made his appearance, probably because they found such a protest altogether unavailing, and explained the conditions on which the earl was willing to surrender to his trial.[4] But in a transaction of this nature we should expect to find him employing a lawyer rather than a clergyman; and accordingly we are informed by Hume that the individual who thus appeared for the Douglases was "Sir John Ballandine, who was then one of their dependers, and afterward justice clerk."[5]

Bellenden, John.

Whatever may have been Bellenden's employment at this period, it is certain that he was soon afterwards an attendant at court; and that at the request of the king he undertook a translation of the Roman history of Livy, and the Scotish history of Boyce.[6] In this formidable task he appears to have been engaged in 1530 and the three ensuing years. The treasurer's accounts contain various entries respecting the remuneration of his labours: the sum total which he is there stated to have received amounts to L.114; namely, L.78 for the translation of Boyce, and L.36 for that of Livy. But this was not the only reward which he obtained. The archdeaconry of Moray had become vacant during the vacancy of the see; and two clergymen, Duncan and Harvey, having solicited the pope in favour of James Douglas, were convicted of treason, and their property escheated to the crown. The annual emoluments arising from the pensions and benefices of John Duncan, who was parson of Glasgow, and from all the property belonging to Alexander Harvey for the two successive years 1536 and 1537, were bestowed upon Bellenden. For the first grant he paid a composition of 350 marks, and for the second, of L.300.[7] It must have been upon the present occasion that he was promoted to the archdeaconry, which had lapsed to the crown in consequence of the vacancy in the bishopric: it was perhaps about the same period that he was appointed a canon of Ross; and this appears to have been the full extent of his preferment in the church, while many worthless and illiterate men were enjoying its highest dignities and emoluments.

His translation of Hector Boyce's history of Scotland is said to have been printed in the year 1536.[8] Neither the title-page nor the colophon exhibits the year of the im-

[6] It is not to be supposed that the king was able to read Latin authors with much facility. Lindsay, vol. i. p. 259, mentions that he was taken from school at the age of twelve; and the metrical paraphrast of Boyce's history has more particularly described the state of his knowledge:

The kingis grace I knaw is nocht perfyte
In Latyn toung.

We cannot however suppose that the king was entirely ignorant of the Latin language. It may perhaps be considered as a proof of his knowledge, that he urged Buchanan to write against the Franciscan friars, and to render his satire more poignant. "Igitur acrius in eos jussus scribere, eam silvam, quæ nunc sub titulo Franciscani est edita, inchoatam regi tradidit." (*Buchanani Vita*, p. 3.) Sir David Lindsay, in a poem composed about this period, exhorts James to study the chronicles of Scotland; and it might possibly be his intention to refer his grace to Bellenden's translation. (*Works*, vol. i. p. 302.)

The cronikillis to knaw I the exhort,
Quhilk may be mirrour to thy majestie;
Thare sall thou find baith gude and evill report,
Of everilk prince efter his qualitie:
Thocht thay be deid, thair deidis sall nocht dee.
Traist weill how salt be stylit in that storie
As thow deservis, put in memorie.

Bellenden, John.

pression; so that the date here assigned, if it is not merely conjectural, must have been ascertained from some other document. The book was printed by Thomas Davidson, who styles himself printer to the king.[1] On the 26th of July 1533, a sum of money was paid to Bellenden "for ane Cronikle gevin to the kingis grace," but this must have been in manuscript. The printed book describes the translator as archdeacon of Moray and canon of Ross: the bishopric did not become vacant till the year 1534,[2] and, as we have already seen, the archdeaconry was vacated at a later period. Under the date of April 1538, when he obtained a grant of the two clergymen's emoluments for the preceding year, he was not described as a dignitary. It has likewise been stated that the work was reprinted in 1541,[3] but such copies as we have had an opportunity of inspecting seem all to belong to the same edition. It was Bellenden's intention to execute a complete version of Livy, but he did not advance beyond the first five books, nor was his translation printed till the year 1822. From a manuscript in the Advocates Library, it was then published by Mr Maitland, to whose antiquarian zeal we are likewise indebted for a new edition of his other translation, as well as for some curious and interesting notices of Boyce and Bellenden.[4] The archdeacon is reported to have continued the history of Scotland for one hundred years subsequent to the period at which the printed narrative closes;[5] and a passage in his Proheme of the History seems to imply that he had at least formed such a project.

Bring nobyll dedis of mony yeris gone
Als fresche and recent to our memorie
As thay war bot in-to our dayis done,
That nobyll men may haue baith laud and glorie
For thair excellent brut of victorie.
And yit becaus my tyme hes bene so schort,
I thynk, quhen I haue oportunite,
To ring thair bell in-to ane othir sort.[6]

These two works exhibit the most ample specimen of ancient Scottish prose that has descended to our times, and are distinguished beyond most others by their fluency and neatness of style. Bellenden frequently surprises a modern reader by the happy vivacity of his expressions; nor can we peruse these translations without being convinced that his learning and talents had qualified him for original composition. In his version of the Scotish historian, he does not adhere very scrupulously to his author; he has assumed the liberty of adding, as well as of retrenching, and may therefore be considered as having exceeded the proper limits of a translation. He has at all events produced a very curious, and, to those who have a competent knowledge of the language, a very entertaining work. To his version of Boyce's history he has subjoined an epistle, addressed to James the Fifth, and written in a strain of manly freedom: of the distinction between a king and a tyrant, and of the miseries to which wicked princes have generally been exposed, he speaks in bold and unequivocal terms, which may excite some degree of surprise, but which cannot fail of exciting a high degree of respect for his character.[7] Bellenden was then a dignitary of the church, and might still hope for preferment; and in all ages ambitious churchmen have been sufficiently disposed to encourage sovereigns in their most flagrant attempts to encroach on the liberties of their subjects; but the conduct of the worthy archdeacon, and of some other beneficed clergymen of the ancient Scottish church, must completely exempt them from this censure. John Mair, who was provost of St Salvator's College, and treasurer of the chapel royal, and Hector Boyce, who was principal of King's College, canon of Aberdeen, and rector of Tyrie, have each written the history of their native country, and have each evinced a laudable zeal in vindicating the unalienable rights of the people. If such sentiments were cherished by some of the catholic clergy, it is not surprising that they should animate the breast of Buchanan, who had never been accustomed to pace in the trammels of the church, and who had more completely imbibed the spirit of classical antiquity.

Bellenden, John.

Whatever might be the liberality of his political sentiments, Bellenden seems to have been unprepared for any change in the national religion.[8] Stern and unbending virtue is not on all occasions to be expected among mankind: truths which threaten the extinction of dignity and emolument cannot so easily be embraced; nor must we forget the invincible force of prejudices, admitted in early youth,

[4] The History and Chronicles of Scotland: written in Latin by Hector Boece; and translated by John Bellenden, archdean of Moray, and canon of Ross. Edinb. 1821, 2 vols. 4to. The first five books of the Roman History: translated from the Latin of Titus Livius by John Bellenden, &c. Edinb. 1822, 4to. The two works are uniformly and elegantly printed.

[5] Balei *Scriptores Britanniæ*, cent. xiv. p. 223.

[6] This metaphor, which is not peculiarly elegant, seems to have been a favourite with the Scotish poets, and particularly with the bishop of Dunkeld.

Ane nothir wyse that bell sall now be roung
Than euer was to fore herd in our toung. (Douglas's *Virgil*, p. 38.)

For quhy the bell of rethorick bene roung
Be Chawcer, Gower, and Lidgate laureat. (Lindsay's *Works*, vol. i. p. 284.)

[7] In the Proheme of the History, Bellenden takes occasion to suggest that it is impossible for a king to possess at once the hearts and the goods of his barons.

Schaw mony reasonis how na king micht haif
His baronis hartis and thair geir atanis.

[8] It however appears from the following stanza of the same Proheme, that he was not insensible to the profligate lives of the clergy.

Schaw how of kirkis the superflew rent
Is ennime to gud religion,
And makis preistis more sleuthfull than fervent
In pietuus werkis and devotion,
And not allanerly perdition
Of commoun weill be bullis sumptuus,
Bot to evill prelatis gret occasion
To rage in lust and life maist vicius.

Bellenden, William.

and cherished through a lengthened life. The archdeacon of Moray is represented as a strenuous opponent of the reformation, which he did not live to see completed.[1] He is said to have visited Rome, and there to have terminated his career in 1550.[2] The particular object of his journey has not been recorded: nor are we better informed with respect to his age; but if he was entered at the university in 1508 and died in 1550, we may conjecture that he had scarcely exceeded his sixtieth year. In this academical record however we are only guided by the identity of names, without the aid of any additional evidence.

Bellenden has been extolled as a master of every branch of divine and human learning,[3] and his attainments have even extorted applause from the zealous bishop of Ossory, John Bale, who has so frequently treated the papists with unrelenting severity. In his poetical remains, which are not numerous, he frequently displays an excursive fancy, with considerable taste and skill as a versifier; and it is therefore to be regretted that so few of his compositions have been preserved. The most poetical of his works is the Proheme of the Cosmographe: the principal incidents are borrowed from the ancient fiction of the choice of Hercules,[4] but he has imparted to his copy the characteristic air of an original. Nor is his Proheme of the History destitute of poetical merit. These two poems, as well as the metrical prologue to his translation of Livy, bear internal evidence of having been composed for the instruction of the young king. Two copies of his unpublished prolusion on the conception of Christ are to be found in Bannatyne's MS.

Beside the works already enumerated, Bellenden is said to have composed a tract on the Pythagorean letter, *De Litera Pythagoræ;* nor is there any necessity to adopt Dr Mackenzie's emendation, and substitute *Vita* for *Litera:* the letter of Pythagoras was upsilon, which he had selected as his favourite in consequence of certain emblematical properties indicated by its form. Vossius has mentioned Bellenden as the author of a work on cosmography,[5] but this is evidently his translation of Boyce's preliminary description of Scotland. It was stated by Dr Campbell that many of his writings were then in the possession of persons of distinction in Scotland; and he particularly mentions that several of his poems were in the possession of Laurence Dundas, apparently the professor of humanity at Edinburgh.[6] It is not however improbable that all these were merely the works with which we are still acquainted, and that the poems to which he alludes were modern transcripts. (D. I.)

Bellenden, *William*, is a Scottish name familiarly known to those who have explored the recesses of modern literature, but with respect to the history of the individual himself very few particulars have hitherto been discovered. Whether he belonged to any family of distinction, we are not informed; nor is the gentility of his birth attested by Dempster, who supplies the only biographical notices with which we are acquainted. According to this contemporary authority, he was a professor in the university, and an advocate in the parliament of Paris. We must apparently conclude that he relinquished the functions of a professor, and betook himself to the practice of the bar. The same writer has stated that both Queen Mary and King James employed him in some diplomatic services, and that the latter nominated him master of requests.[7] That he bore such a title, is sufficiently ascertained from his own publications, in all of which he is described as "Magister supplicum Libellorum Augusti Regis Magnæ Britanniæ;" but there are obvious reasons for suspecting that his office, if not unconnected with emolument, was altogether unconnected with official duty; for he appears to have spent the greater part of his life in France. *Magister Libellorum* was an officer in the court of the Roman emperors,[8] and it was his duty to receive and examine petitions addressed to the prince. A similar office was established in several modern kingdoms; and *Maître des Requêtes* being an honourable title in France, Bellenden might solicit and obtain such a title from a sovereign who could not so easily bestow an ample salary. The terms employed by Dempster in describing his appointment, seem rather to indicate honour than emolument. It is supposed that he must have belonged to the Scottish establishment, for, in England, a person who bore this title was a judge of a particular court: of the court of requests, which professed to distribute justice gratuitously, the lord privy seal was chief judge, and was assisted by two judges called masters of requests, the one for the common, and the other for the civil law.[9] In a list of the officers of state in Scotland, "William Ballenden, *magist. supplic. libellor.*" is said to have succeeded Mark Ker as master of requests in 1608, and to have been succeeded in 1624 by Sir James Galloway, afterwards Lord Dunkeld.[10] But the date of his appointment seems to have been borrowed from that of his earliest publication; and Bellenden continued to describe himself as master of requests in the year 1625.

If he practised at the bar in Paris, his early education must in all probability have been French; and if he was a regent or professor in one of the colleges, he may be supposed to have adhered to the popish religion. Since the massacre of St Bartholomew, which had proved fatal to Ramus and other men of learning, there probably had been no protestant professor in any college of Paris. His nephew, William Bellenden, was a catholic and a priest.

Bellenden's earliest publication bears the subsequent

Bellenden, William.

title: "Ciceronis Princeps, Rationes et Consilia bene gerendi firmandique Imperii: ex iis repetita quæ ex Ciceronianis defluxere fontibus in libros xvi. de Statu Rerum Romanarum, qui nondum lucem acceperunt." Paris. 1608, 8vo. This was followed by[1] "Ciceronis Consul, Senator, Senatusque Romanus: illustratus publici observatione juris, gravissimi usus disciplina, administrandi temperata ratione; notatis inclinationibus temporum in Rep. et actis rerum in Senatu: quæ a Ciceroniana nondum edita profluxere memoria annorum DCCX. congesta in libros xvi. de Statu Rerum Romanarum: unde jam manavit *Ciceronis Princeps*, dignus habitus summorum lectione principum. Editio prima. Ad inclytum serenissimumque Principem Henricum Principem Scotiæ et Walliæ." Paris. 1612, 8vo. This mode of noting a first edition is somewhat pleasant;[2] nor must we overlook the important intelligence that his former publication had been thought worthy of the attention of mighty princes. Both these works partake of the nature of a cento. In the first of them, the author has collected from the writings of Cicero the various precepts and remarks which relate to the origin and principles of regal government, and with no small labour has combined the whole in a regular and systematic form. Adopting a similar plan in the other work, he has compiled a treatise on the dignity and authority of the consuls, and on the constitution of the Roman senate. Although this may seem an effort of mere diligence, it required both learning and ability to present such materials in such a shape.

His next publication is entitled "De Statu prisci Orbis in Religione, Re politica, et Literis, liber unus. Ad serenissimum Principem Carolum Principem Scotiæ et Walliæ" Paris. 1615, 8vo. This is a work of more originality, and affords a very favourable specimen of the author's talents and erudition.[3] It exhibits, in a very condensed form, a sketch of the history of philosophy and civil polity, tracing its progress among the Hebrews, Greeks, and Romans. Of this work very few copies appear to have been separately published; for the author speedily combined all the three tracts in a volume which bears the following title: "De Statu libri tres. I. De Statu prisci Orbis in Religione, Re politica, et Literis. II. Ciceronis Princeps, sive de Statu Principis et Imperii. III. Ciceronis Consul, Senator, Senatusque Romanus, sive de Statu Reip. et Urbis imperantis Orbi. Primus, nunc primum editus: cæteri, cum tractatu de Processu et Scriptoribus Rei Politicæ, ab autore aucti et illustrati." Paris. 1615, 8vo. Notwithstanding this notice on the title-page, we suspect that the second and third treatises were not actually reprinted. Each treatise has a distinct series of pages, and it was therefore easy to combine the whole. In its separate form and in this volume, *Ciceronis Consul* exhibits the very same list of typographical errors. Dr Parr remarks, that in all the copies which he had seen, the date seems to have been changed from M.DC.XV. to M.DC.XVI. by the printer adding the letter I after the impression had been finished: but in a copy belonging to the Advocates Library, the additional letter is apparently printed, not with a type, but with a pen; and in a copy belonging to the writer of this notice, the original date remains unaltered. Another minute variation may likewise be mentioned; in the latter copy, the plate in the second treatise is not impressed on the reverse of a printed page of the dedication. In a paper written by Dr Bennet, the late bishop of Cloyne, we find the subsequent statement respecting the books *De Statu*. "The great work being now completed, Bellenden looked forward with a pretty well-grounded expectation for that applause which his labour and his ingenuity deserved. But his views were disappointed, by one of those events which no art of man could foresee or remedy. The vessel in which the whole impression was embarked was overtaken by a storm before she could reach the English coast, and foundered with all her cargo. A very few copies only, which the learned author either kept for his own use, or had sent as presents by private hands, seem to have been preserved from the destruction which awaited the others."[4] We are not aware of any early authority for such a statement; and the learned prelate, misled by an imperfect recollection, seems to have misapplied Dr Warton's account of Bellenden's larger work, which is likewise an account that requires confirmation. There is a manifest fallacy in supposing that almost all the impression of such a book must have been destined for England. After a long interval, the fame of the author was greatly extended by Dr Parr's publication of "Gulielmi Bellendeni, Magistri supplicum Libellorum Augusti Regis Magnæ Britanniæ, &c. de Statu libri tres. Editio secunda longe emendatior." Lond. 1787, 8vo. The preface, extending to seventy-six pages, is written in a style of elegant and powerful Latinity, but is too much replenished with modern politics, and, in the opinion of some readers, is not free from a considerable mixture of pedantry. It is however such a composition as no other Englishman of that period could perhaps have produced.

Bellenden, William.

The last work which Bellenden himself published is of very small extent, consisting merely of two short poems: "Caroli Primi et Henricæ Mariæ, Regis et Reginæ Magnæ Britanniæ, &c. Epithalamium; et in ipsas augustissimas Nuptias, celeberrimamque Legationem earum causa obitam, &c. panegyricum Carmen, et Elogia." Paris. 1625, 4to. This little work has likewise been republished by Dr Parr.

But the greatest labour of his life was a posthumous production, which made its appearance under the title of "Guilielmi Bellendeni Scoti, Magistri supplicum Libellorum Augusti Regis Magnæ Britanniæ, de tribus Luminibus Romanorum libri sex-decim." Paris. 1633, fol. With respect to the date of this publication, one bibliographer frequently contradicts another, and some minute particulars require explanation. In the Advocates Library, that great repository of Scottish literature, there are two copies of the book, which exhibit considerable variations. In both of them we find the same extract of the royal privilege, dated on the third of September 1631. The one bears, "Achevé d'imprimer pour la premiere fois, le vingtseptiesme jour d'Aoust 1633." Of this copy the dedication, "Henrico Borbonio, Sacro-sancti Imp. Rom. Principi, illustriss. Metens. Præsuli," is subscribed by the author's nephew, "Guilielmus Bellendenus, Presbyter Scotus." It consists of nearly four pages, but is not fol-

---

[1] This work of Bellenden did not escape the notice of the learned and indefatigable Fabricius, *Bibliographia Antiquaria*, p. 490. edit. Hamb. et Lips. 1716, 4to.

[2] Another learned philologer had recently set him the example: "Julii Cæsaris Bulengeri Juliodunensis de Theatro Ludisque Scenicis libri duo. *Editio prima.*" Tricassibus, 1603, 8vo.

[3] Dr Parr, in his famous preface to Bellenden, p. v. mentions this work with much commendation. "Stylus est Bellendeni per librum huncce, dilucidus in primis, neque exquisitus nimis. Sententiæ hic illic occurrunt reconditæ, quibus adhibita, tanquam obrussa, est ratio. Operis porro totius ita sunt aptæ inter se colligatæque partes, nihil ut sit asperum, vel hiulcum, vel dissolutum, nihil in alienum irruerit locum, nihil non positum sit suo."

[4] See Dr Johnstone's *Memoirs of Parr*, p. 182.

Bellenden, William.

lowed by a preface. The other copy has a similar title-page, but with the date of 1634; and the note subjoined to the privilege bears, "Achevé d'imprimer pour la premiere fois, le vingtroisiesme jour de Mars 1634." It contains a different and a shorter dedication, "Potentissimo et invictissimo Principi Carolo Magnæ Britanniæ Regi, &c." subscribed by the publisher, Toussaint du Bray. This dedication is followed by a brief preface, "Lectori benevolo." In other respects the two copies present a complete resemblance; and it appears sufficiently evident that one set of copies must have been intended for the French, and another for the British market.

Of this elaborate work, which consists of no fewer than 824 pages, printed on a small type, the subject is very faintly indicated by the title. It is the author's object to combine, in an historical form, all the statements and reflections of Cicero which relate to the civil and religious affairs of Rome; and his plan is executed in such a manner as to display the essence of the Roman history, from the foundation of the city to the extinction of the republic.[1] In the text he adheres to his former method of expressing himself in no other words than those of Cicero; but he has interspersed occasional observations, drawn from various sources of information. The latter part of the work, relating to the times of his great prototype, is very ample and satisfactory; and here it is evident that the materials must be chiefly derived from the epistles. The reader cannot fail to perceive that this is precisely such a digest as would be necessary for an historian of the life and times of Cicero; it is such a digest as Dr Middleton professes to have formed by his own unaided industry. "My first business therefore," as he is pleased to state, "after I had undertaken this task, was, to read over Cicero's works, with no other view than to extract from them all the passages that seemed to have any relation to my design; where the tediousness of collecting an infinite number of testimonies scattered through many different volumes; of sorting them into their classes, and ranging them in proper order; the necessity of overlooking many in the first search, and the trouble of retrieving them in a second or third; and the final omission of several through forgetfulness or inadvertency; have helped to abate that wonder which had often occurred to me, why no man had ever attempted the same work before me, or at least in this enlarged and comprehensive form, in which it is now offered to the public."[2] If previously acquainted with the work of Bellenden, he must have been fully aware that this labour of collecting and digesting was altogether superfluous; nor is it probable that such a book was unknown to Dr Middleton, a man of extensive learning, and the keeper of a great public library, that of the university of Cambridge. He has therefore been repeatedly accused of plagiarism; and it must be confessed that the accusation does not appear to be destitute of foundation. "It may be worth observing," says Dr Warton, "that he is much indebted, without acknowledging it, to a curious book little known, entitled *G. Bellendeni Scoti de tribus Luminibus Romanorum*, &c. It comprehends a history of Rome, from the foundation of the city to the time of Augustus, drawn up in the very words of Cicero, without any alteration of any expression. In this book Middleton found every part of Cicero's own history, in his own words, and his works arranged in chronological order, without further trouble. The impression of this work being shipped for England, was lost in the vessel, which was cast away, and only a few copies remained that had been left in France."[3] The same opinion respecting the biographer's plagiarism is adopted, and strongly expressed by Dr Parr.[4]

Bellero-phon.

M. Morabin, the French biographer of Cicero, who soon followed Dr Middleton, has, in the dedication of his work, acknowledged his acquaintance with Bellenden, but has not mentioned him in the most appropriate terms. "Si Bellenden, dans son traité *De tribus Luminibus Romanorum*, a évité cet écueil, en rassemblant tout ce qu'il y a d'historique dans Cicéron, et en n'employant que les expressions de cet orateur, il a donné dans un autre; et sa compilation, de quelque utilité qu'elle puisse être à un auteur qui embrasseroit une histoire générale, ne sauroit guère servir dans la composition d'une histoire particulière, qu'à fournir la matière d'un gros livre qui ne seroit lu."[5] But certainly an ample collection of materials was in either case desirable; and for a person who undertook to write the history of Cicero in two volumes quarto, it might have been thought necessary to inspect all the materials which Cicero had himself furnished.

Bellenden has bestowed upon his book a title which to many readers must require explanation. It appears to have been his original intention to compose, on a similar plan, three different works illustrative of the civil and literary history of Rome. The first of his three luminaries is Cicero, who has supplied him with the materials of civil history. According to Lenglet du Fresnoy, the other two whom he had in his contemplation were Seneca and the elder Pliny;[6] and we may conclude that, by means of the same laborious arrangement and digest of their respective writings, he intended to exhibit a comprehensive view of the moral and physical science of the Romans. (D. I.)

BELLEROPHON or BELLEROPHONTES, in fabulous history, the name given to Hipponous the son of the Corinthian king Glaucus and Eurymede, after his murder of the noble Corinthian Bellerus. In order to expiate his crime, he fled to Prœtus, whose wife Anteia or Stenebœa, became enamoured of the young stranger; and when he rejected her advances she accused him to the king of an attempt against her honour. Prœtus, unwilling to infringe the laws of hospitality, made Bellerophon the bearer of his own death warrant in a sealed letter addressed to his father-in-law Iobates king of Lycia; whence the proverb *Bellerophontis literas affert*, equivalent to "Uriah's letter." As a certain means of destruction, Bellerophon was sent to kill the Chimæra; but with the assistance of the winged horse Pegasus he rose into the air, and slew the monster with his arrows. The like success attended his expeditions against the Solymi and the

---

[1] Clement has described this work in terms of too extensive import: "Guillaume Bellenden, grand admirateur de Cicéron, s'est donné la torture pour écrire l'Histoire *des Empereurs* et des Consuls Romains, avec les propres termes de cet ancien orateur, dont il a cité constamment les ouvrages à la marge: et comme il n'osoit pas s'étendre à son gré, en écrivant d'une manière si bornée, il a ajouté des notes à la fin de chaque livre, dans lesquelles il explique plus amplement ses idées." (*Bibliothéque curieuse historique et critique, ou Catalogue raisonné de Livres difficiles à trouver*, tom. iii. p. 72.)

[2] Middleton's *Hist. of the Life of M. T. Cicero*, vol. i. p. xx.

[6] "L'auteur avoit dessein de faire la même chose sur Pline l'ancien, et sur Seneque; mais il n'y a eu d'imprimé que ce qui regarde Cicéron, et l'ouvrage même n'est pas commun." (Lenglet du Fresnoy, *Méthode pour étudier l'Histoire*, tom. xi. p. 72, edit. 1772.)

Belles-Lettres || Bellini.

Amazons; and on his return to Lycia he slew a party of the bravest Lycians who were set in ambush against his life Iobates, in admiration of his valour, and convinced that his innocence alone could have shielded him in all these perils, gave him his daughter in marriage, and nominated him his successor in the kingdom; intelligence that drove Stenebœa to despair and suicide. Bellerophon now grew vain of his prosperity; and as he attempted, with the assistance of Pegasus, to ascend to heaven, Jupiter checked his presumption by sending a gadfly which stung the horse, and caused Bellerophon's fall to the earth, where he wandered in contempt and misery to the end of his days: while Pegasus, mounting to heaven, was placed among the constellations.

BELLES-LETTRES, a French term for polite literature generally. It would be endless to enumerate the various branches both of science and literature which learned men have thought proper to comprehend under this title. Rhetoric, poetry, history, and philology, are usually included under *belles-lettres;* but the vagueness of the term has rendered its use nearly obsolete, though it is still retained in some universities.

BELLEVOIS, an excellent painter of marine subjects, but of whose history nothing is recorded except that he died at Hamburg in 1684.

BELLEY, a town of France, in the department of Ain, and capital of an arrondissement of the same name, is situated near the Rhone, 39 miles east of Lyons. It is the seat of a bishopric founded as early as 412, and contains an episcopal palace, an ecclesiastical school, a museum, and a public library. In the vicinity are the best lithographic stones in France. Pop. (1851) 4517. The arrondissement comprehends nine cantons and 112 communes, with a population of 83,626.

BELLINI, Gentile, a Venetian painter, born in the year 1421. He was employed by the republic of Venice; and to him and his brother that state is indebted for the noble works which are to be found in its council-hall. Mahommed II. having seen some of his performances, was so struck with them that he wrote to the republic, entreating that the artist might be sent to him. Bellini accordingly proceeded to Constantinople, where he painted a number of pieces, among which was the decollation of St John the Baptist, whom the Turks revere as a great prophet. Mahommed admired the proportion and shading of the work; but remarking a defect in regard to the skin of the neck, from which the head was separated, the sultan, to prove the truth of his observation, sent for a slave and ordered his head to be struck off. The painter by no means relishing this capital style of instruction, and, anxious to place his own head beyond the reach of experiment, earnestly solicted his dismission, which was granted by the grand signior. The republic settled a pension upon him at his return, and made him a knight of St Mark. He died in 1501, in the eightieth year of his age.

Bellini, *Giovanni*, the son of Jacopo Bellini, and brother of Gentile, was born at Venice in 1422. He surpassed his brother in grace and softness; and may be considered as the chief emancipator of the Venetian school from the dry manner of his predecessors. His works are numerous, but his best pictures are to be seen only in Italy. (Lanzi, *Storia Pittor.*)

Bellini, *Jacopo*, an early Venetian painter, who having learned the art of painting in oil, produced some pictures in that manner which are still considered as remarkable productions. He died in 1470.

Bellini, *Lorenzo*, a celebrated physician and anatomist, born at Florence A.D. 1643. After completing his studies in general literature, he went to Pisa, where, assisted by the generosity of the grand duke Ferdinand II., he studied under two of the most learned men of that age, Oliva and Borelli, the former of whom instructed him in natural philosophy, and the latter in mechanics. He likewise studied medicine under Redi, and mathematics under Marchetti. At the early age of twenty he was chosen professor of philosophy at Pisa, but did not long continue in this office; for he had acquired such a reputation for skill in anatomy, that the grand duke procured him a professorship in that science, and was himself a frequent auditor at his lectures. Bellini died in 1703, in the sixtieth year of his age. His works were publicly read and explained at Leyden by our countryman Dr Pitcairn, professor of physic there.

Bellini || Belon.

Bellini, *Vincenzio*, the operatic composer, was born at Catania in Sicily, on the 3d November 1802 according to the best authorities. He was the son of a musician, and received his education in the Conservatorio at Naples, under Zingarelli. His principal works are the following well-known operas:—*Il Pirata, La Straniera, La Sonnambula, Norma, I Puritani.* He died at Puteaux near Paris, after a short illness, September 23. 1835. Combined with an elegant person and fascinating manners, Bellini possessed high moral worth; and his compositions, which are characterized by tenderness and sweetness, are a happy reflection of the amiable disposition of the author.

BELLIS, a genus of composite plants, the best known of which is the common daisy. See Botany.

BELLONA, in *Roman Mythology*, the goddess of war, and the companion of Mars. Some, however, describe her as his sister or his wife. She is commonly represented in an attitude expressive of fury and distraction, with her hair composed of snakes clotted with gore, and her garments stained with blood; sometimes she is depicted driving the chariot of Mars, with a bloody whip in her hand, sometimes with a lighted torch or brand, and a trumpet. Bellona had a temple at Rome near the Circus Flaminius. Her priests, called Bellonarii, used to mangle their bodies with knives in order to pacify the deity, offering their own blood in sacrifice.

BELLORI, Giovanni Pietro, an eminent antiquary and connoisseur, born at Rome in 1615. He wrote *Vite de' Pittori, Scultori, ed Architetti, Moderni*, 4to, Rome 1672, of which the first part only was printed; and he was also the author of various works on antiquities and medals. He died in 1696.

BELLOVĂCI, a people of Gallia Belgica, the most powerful and bravest of the Belgæ. In Cæsar's time they could bring 100,000 men into the field.

BELLOWS, a machine so contrived as alternately to inspire and expire the air, by enlarging and contracting its capacity. See Blowing Machines.

BELLUNO, one of the delegations into which the Austrian kingdom of Venetian Lombardy is divided. It is bounded on the west and north by the Tyrol, on the east by Friuli, on the S.E. by Treviso, and on the S.W. by Vicenza. Its extent is 1240 square miles, or 793,600 acres. It is generally a hilly and mountainous country. The widest valley is that through which runs the river Piave, and which, like several other much narrower ones, is tolerably fertile in rye, barley, oats, and buckwheat; while some parts yield a little wheat, much maize, and some flax and hemp. The mountains contain veins of iron, lead, copper and vitriol; but the mines are all worked upon a very contracted scale. The population amounted in 1817 to 114,772, in 1827 to 122,840, and in 1851 to 157,120. The capital, of the same name, stands at the confluence of the Piave and the Ardo. Besides the cathedral, there are thirteen churches, and several religious houses for males and for females. The inhabitants amount to 9800, some of whom are employed in the spinning of silk. Long. 12. 8. 46. E. Lat. 46. 7. 46. N.

BELOMANCY (*βέλος* and *μαντεία*), a kind of divination by means of arrows drawn at random from a bag or quiver; practised by the ancient Scythians, Babylonians, Arabians, and other Eastern people. (See Ezekiel xxi. 21.)

BELON, Pierre, a distinguished French naturalist, born at the hamlet of Soulletière, in Le Maine, about the year 1517. He published several works in Latin and in French, including a book of travels, or observations of many singularities

Beloochistan.

and memorable things found in Greece, Asia, Judæa, Egypt, and other foreign countries. Botany and zoology are particularly indebted to Belon; and he may be considered as the great reviver of the study of natural history. He was murdered near Paris by one of his enemies in 1564.

Boundaries.

BELOOCHISTAN, a country of Asia, situate on the north-western coast of the Indian Peninsula. It is bounded on the N. by Afghanistan; on the E. by Sinde; on the S. by the Persian Gulf and the Arabian Sea; and on the W. by Persia. It extends from Lat. 24. 50. to 30. 20., and from Long. 57. 56. to 68. 38.; its extreme length from E. to W. being 660 miles, and its breadth 370.

The outline of the sea-coast is in general remarkably regular, running nearly due E. and W., a little N. of Lat. 24. 46. from Cape Monze, on the border of Sinde, in Long. 66. 35., to Cape Zegin, in Long. 58. 4. It is for the most part craggy, but not remarkably elevated, and has in some places, for considerable distance, a low sandy shore, though almost everywhere the surface becomes much higher inland. The principal headlands, proceeding from E. to W., are Cape Monze or Ras Moarree, which is the eastern headland of Sonmeanee Bay; Goorab Sing, Ras Arubah, Ras Noo, forming the western headland of Gwadel Bay; Ras Jewnee, forming the eastern point of Gwettar Bay, and Cape Zegin at the western extremity. There is no good harbour along the coast, though extending about 600 miles; but there are several roadsteads with good holding-ground, and sheltered on several points. Of these the best are Sonmeanee Bay and Choubar Bay, at which last point is the only place on the coast deserving the name of a town, there being elsewhere nothing but small and wretched villages.

History.

Of the early history of this portion of the Asiatic continent little or nothing is known. The poverty and natural strength of the country, combined with the ferocious habits of the natives, seem to have equally repelled the friendly visits of inquisitive strangers and the hostile incursions of invading armies. The first distinct account which we have is from Arrian, who, with his usual brevity and severe veracity, narrates the march of Alexander through this country, which he calls the country of the Oritæ and Gadrosii. He gives a very accurate and judicious geographical account of this forlorn tract, its general aridity, and the necessity of obtaining water by digging in the beds of torrents; describes the food of the inhabitants as dates and fish; adverts to the occasional occurrence of fertile spots, the abundance of aromatic and thorny shrubs and fragrant plants, and the violence of the monsoon in the western part of Mekran. He notices also the impossibility of subsisting a large army, and the consequent destruction of the greater part of the men and beasts which accompanied the expedition of Alexander. At the commencement of the eighth century, this country was traversed by an army of the kaliphate.

The Belooches are, with few exceptions, Mahommedans of the Soonnee persuasion. They date their origin from so late a period as the Mahommedan invasion of Persia, and are very desirous of being supposed to be of Arabian extraction; but the latter part of this supposition derives no confirmation from their features, their manners, or their language, which bear not the slightest similitude to those of the Arabs. There can be little doubt, however, that they originally came from the westward; of which indeed there is strong evidence in the affinity between the Beloochekee and Persian languages; and their institutions, habits, and religion, seem to indicate that they are of Turkoman lineage. It appears highly probable, indeed, that, during the frequent sanguinary revolutions to which the monarchy of the Seljukide Tartars was subject, some of these barbarians had been forced to wander over the country in quest of new settlements; and that a portion of them had found refuge in the mountainous districts of Beloochistan. But, besides the Belooches, there are in Beloochistan other distinct tribes of inhabitants. These are, the Brahooés, apparently a race of Tartar mountaineers, who settled at an early period in the southern parts of Asia, but whose history is extremely obscure and uninteresting; the Dehwars, a Persian colony, whose original settlement cannot be traced; and the Hindus, who appears to have been the first settlers in the upper part of the Brahooick Mountains, on their being expelled from Sinde, Lus, and Mekran, by the armies of the khalifs of Baghdad. This last tribe appears for a time to have constituted the governing party. Beloochistan was subsequently exposed to the transient and devastating inroads of the Moguls, and became nominally a portion of the dominions of the Emperor Akbar. The Brahooés and Belooches, however, gradually spread over the country; and the Hindu power was at length subverted by a revolution, which placed the ancestors of the present khan of Kelat upon the throne.

Beloochistan.

The precise period at which this revolution took place cannot be accurately ascertained; but it is probable that two centuries have not elapsed since that event. The last rajah of the Hindu dynasty found himself compelled to call for the assistance of the mountain shepherds, with their leader, Kumbur, in order to check the encroachments of a horde of depredators, headed by an Afghan chief, who infested the country, and even threatened to attack the seat of government. Kumbur successfully performed the service for which he had been engaged; but having in a few years quelled the robbers against whom he had been called in, and finding himself at the head of the only military tribe in the country, he formally deposed the rajah, and assumed the reins of government.

The history of this country subsequently to the accession of Kumbur is involved in the same obscurity as during the Hindu dynasty. It would appear, however, that the sceptre was quietly transmitted to the descendants of that chief, who seem to have persevered in a peaceable system of government, until the time of Abdulla Khan, the fourth in descent from Kumbur; who, being an intrepid and ambitious soldier, turned his thoughts towards the conquest of Kutch-Gundava, then held by different petty chiefs, under the authority of the Nawaubs of Sinde.

After various success, the Kumburanees at length possessed themselves of the sovereignty of a considerable portion of that fruitful plain, including the chief town, Gundava. It was during this contest that the famous conqueror Nadir Shah, commonly called Thamas Koolee Khan, advanced from Persia to the invasion of Hindustan; and while at Kandahar, he despatched several detachments into Beloochistan, and established his authority in that province. Abdoolla Khan, however, was continued in the government of the country by Nadir's orders; but he was soon after killed in a battle with the forces of the Nawaubs of Sinde. He was succeeded by his eldest son, Hajee Mohummud Khan, who abandoned himself to the most tyrannical and licentious way of life, and completely alienated his subjects by his arbitrary and oppressive system of taxation. In these circumstances Nusseer Khan, the second son of Abdulla Khan, who had accompanied the victorious Nadir to Delhi, and acquired the favour and confidence of that monarch, returned to Kelat, and was hailed by the whole population as their deliverer. Finding that expostulation had no effect upon his brother, he one day entered his apartment when the prince was alone, and stabbed him to the heart. As soon as the tyrant was dead, Nusseer Khan mounted the *musnud*, amidst the universal joy of his subjects, and immediately transmitted a report of the events which had taken place to Nadir Shah, who was then encamped near Kandahar. The shah received the intelligence with satisfaction, and despatched a firman, by return of the messenger, appointing Nusseer Khan beglierbey of all Beloochistan. This event took place in the year 1739.

Beloochistan.

Nusseer Khan proved an active, politic, and warlike prince. He took great pains to re-establish the internal government of all the provinces in his dominions, and improved and fortified the city of Kelat. On the death of Nadir Shah in 1747, he acknowledged the title of the king of Cabûl, Ahmed Shah Abdalla. In 1758 he declared himself entirely independent; upon which Ahmed Shah despatched a force against him, under one of his ministers. The khan, however, levied his troops and totally routed the Afghan army. On receiving intelligence of this discomfiture, the king himself marched with strong reinforcements, and a pitched battle was fought, in which Nusseer Khan was worsted. He retired in good order to Kelat, whither he was followed by the victor, who invested the place with his whole army. The khan made a vigorous defence; and, after the royal troops had been foiled in their attempts to take the city by storm or surprise, a negotiation was proposed by the king, which terminated in a treaty of peace. By this treaty it was stipulated that the king was to receive the cousin of Nusseer Khan in marriage; and that the khan was to pay no tribute, but only, when called upon, to furnish troops to assist the royal armies, for which he was to receive an allowance in cash equal to half their pay.

Subsequently to this period, the khan frequently distinguished himself by his gallantry and judgment in the wars carried on by the monarch of Cabûl; and, as a reward for his eminent services, the king bestowed upon him several districts to hold in perpetual and entire sovereignty. Having succeeded in quelling a dangerous rebellion, headed by his cousin Beheram Khan, this able prince at length died at an extreme old age, after a long and prosperous reign, in the month of June 1795, leaving three sons and five daughters. He was succeeded by his eldest son, Muhmood Khan, then a boy about fourteen years of age. During the reign of this prince, who has been described as a very humane and indolent man, the country was distracted by sanguinary intestine broils; the governors of several provinces and districts withdrew their allegiance; and the dominions of the khans of Kelat gradually so diminished, that they now comprehend only a small portion of the provinces which were formerly subject to Nusseer Khan.

In 1839, when the British army advanced through the Bolan Pass towards Afghanistan, the conduct of Mehrab Khan, the ruler of Beloochistan, was considered so treacherous, hostile, and dangerous, as to require "the exaction of retribution from that chieftain," and "the execution of such arrangements as would establish future security in that quarter." General Willshire was accordingly detached from the army of the Indus at Quetta to assault Kelat. A gate was knocked in by the field-pieces, and the town and citadel were stormed in a few minutes. Above 400 Belooches were slain, among them Mehrab Khan himself; and 2000 prisoners were taken. The British force consisted of 1049 men. In the following year Kelat changed hands, the governor established by the British, together with a feeble garrison, being overpowered. At the close of the same year, it was re-occupied by the British under General Nott. In 1841, Nadir Khan, the youthful son of the slain Mehrab Khan, was recognised by the British, who soon after evacuated the country.

The territories of Beloochistan are now comprised under the following divisions—Ihalawan, Sarawan, Kelat, Mekran, Lus, Kutch-Gundava, and Kohistan.

Physical aspect; Mountains.

The most remarkable features of this extensive country are its rugged and elevated surface, its barrenness, and its deficiency of water. A stupendous range, to which the appellation of the Brahooick Mountains has been assigned, and which seems to be the primitive root of all the others, springs abruptly to a conspicuous height out of the sea, at Cape Moaree, or Monze, in E. Long. 66. 58. N. Lat. 25., whence it takes a north-easterly direction for about ninety miles. There it projects a ridge, E. by N., the base of which is washed by the river Indus, at the fort of Sehwan. From the separation of this arm, in Lat. 25. 45. to that of 30., the primitive body runs due N., marking the western limits of Sinde, Kutch-Gundava, and a part of Seistan; and from thence it once more regains its original inclination to the N.E., and decreases in magnitude and elevation so rapidly, that, in the course of forty miles, it sinks to a level with the hills inhabited by the Kaukers and other Afghan tribes, with which it becomes incorporated. To the westward the Brahooick Mountains send forth many collateral chains, some of which extend the whole length of Beloochistan, and join the mountains of Persia; others elongate southward till they touch the sea, or come within a few miles of it, and then either take the inclination of the coast or subside in the low and barren plains in its vicinity. The main body, or rather its western face, stretches away N.W. by N., to the 28th degree of N. latitude, where it meets the south-eastern corner of the sandy desert, about the 64th degree of E. longitude: from thence it inclines with a northern aspect between the N.E. and N. points of the compass to Nooshky, in latitude 30° N.; from which place it runs more easterly, till at length it gradually sinks, like the eastern front, to an equality of size with the Afghan hills. Besides the Brahooick chain, there are several other ranges of mountains, extending in various directions and ramifications throughout Beloochistan, but all of them inferior to the former in magnitude and height. This stupendous chain is believed to attain its greatest altitude at Kelat; from which city, according to the natives, a traveller, whatever route he may pursue, must descend; but the descent is so very trifling for a long way on either side of that capital that it is not perceptible by the eye.

Beloochistan.

In brief, Beloochistan may be described as one maze of mountains, except on the N.W.; in which direction the surface descends to the Great Desert on the S., where a low tract stretches along the sea-shore, exhibiting a dreary waste of inconsiderable rocks or dry barren sands, and for a small extent on the E., where the burning plain of Kutch-Gundava extends along the eastern base of the Hala Mountains. From this plain to the elevated table-land lying to the W., the eastern face of the mountain range is furrowed by two long and very deep ravines, through which the Bolan (called by Pottinger "Koahee") and Moola Rivers hold their way. Along the courses of these rivers lie the celebrated passes bearing their names, and affording the means of communication between the valley of the Indus and Beloochistan.

Rivers.

In the northern part of Beloochistan, the only rivers of any importance are the two just mentioned, and these are little more than prolonged torrents, being ultimately lost in the sands of Kutch-Gundava. Pottinger observes that "there is not a single body of running water in this part of the country worthy of a higher appellation than that of a rivulet, unless when swollen by partial floods to a tumultuous and unfordable torrent, nor one even of that description that can be said to flow through a regular and unbroken channel to the main." The southern part abounds in torrents, which rise in the mountains, and cross the low sandy tract lying between them and the ocean. Near the base of the mountains the channels are very small, and in the dry season are filled with vegetation. Towards the coast they are much broader and deeper. Of this description of watercourse is the Hub, rising in that part of the Hala Mountains which separates Beloochistan and Sinde. After heavy rains, it rushes down with a vast body of water; but on the setting in of dry weather the flow ceases; there is no longer any stream, the bed containing merely a few pools. The Poorally, another of these torrents, farther west, has generally a very inconsiderable stream, which in long-continued dry weather totally ceases at Lyarce, about twenty miles

Beloochistan.

from its mouth. Below that town it becomes a creek of the sea, navigable for small boats. The Aghor, farther west, passes by Hinglaj, the celebrated place of Hindu pilgrimage. It is thought to have a longer course than most of the streams along this coast, and to rise amidst mountains frequently covered with snow, as, at the setting in of hot weather its waters, as is the case with such rivers, become higher. Proceeding westward from Hinglaj to the mouth of the Dustee, a distance of 250 miles, we find that only a few small rivulets occur. The Dustee, where Pottinger crossed it, was, within 100 yards of the beach, about 20 inches deep, and 20 yards wide; yet, if his opinion be correct, it has a course of nearly 1000 miles, rising in the Gurmsehl, near the southern course of the Helmund river. The upper part, called the Boordoor, makes its way, in the wet season, through the loose and parched sands of the desert south of Seïstan; but for the greater part of the year its channel is a dry ravine. Pottinger makes a bold, yet perhaps not improbable, conjecture, that this was formerly a channel through which the superfluous water of the valley of the Helmund was discharged into the ocean, but that now the whole is carried off by means either of absorption or of evaporation from the swamp of Hamoon. Westward of the Dustee there are only a few small brooks, which discharge themselves into the sea, and, in fact, along the whole distance of 600 miles, through which the coast of Beloochistan extends, there is no stream which might not in dry weather be forded by a child.

Climate and soil.

The climate of Beloochistan is extremely various in the different provinces. The soil in general is exceedingly stony. In the province of Kutch-Gundava, however, the soil is rich and loamy, and so very productive, that, it is said, were it all properly cultivated, the crops would be more than sufficient for the consumption of the whole of Beloochistan.

Minerals.

Gold, silver, lead, iron, tin, antimony, brimstone, alum, sal-ammoniac, and many kinds of mineral salts, and saltpetre are found in various parts of the country. The precious metals have only been discovered in working for iron and lead, in mines near the town of Nal, about 150 miles S.S.W. of Kelat. The different other minerals above enumerated

Vegetable products.

are very plentiful. The gardens of Kelat produce many sorts of fruit, which are sold at a very moderate rate, such as apricots, peaches, grapes, almonds, pistachio-nuts, apples, pears, plums, currants, cherries, quinces, figs, pomegranates, mulberries, plantains, melons, guavas, &c. All kinds of grain known in India are cultivated in the different provinces of Beloochistan, and there is abundance of vegetables. Madder, cotton, and indigo are also produced; and the latter is considered superior to that of Bengal. The culture of the date fruit is conducted with great attention in the province of

Animals.

Mekran. The domestic animals of Beloochistan are horses, mules, asses, camels, dromedaries, buffaloes, black-cattle, sheep, goats, dogs, and cats, besides fowls and pigeons; but there are neither geese, turkeys, nor ducks. The wild animals are lions, tigers, leopards, hyenas, wolves, jackals, tiger-cats, wild dogs, foxes, hares, mangooses, mountain goats, antelopes, elks, red and moose deer, wild asses, &c. Of birds they have almost every species to be met with either in Europe or India.

City of Kelat.

The principal city of this country is Kelat, the capital of the whole of Beloochistan. This city stands on an elevated site on the western side of a well-cultivated plain or valley, about eight miles long and two or three broad, a great part of which is laid out in gardens and other inclosures. The town is built in an oblong form, and on three sides is defended by a mud wall, eighteen or twenty feet high, flanked, at intervals of 250 yards, by bastions, which, as well as the wall itself, are pierced with numerous loopholes for matchlock-men. The defence of the fourth side of the city has been formed by cutting away perpendicularly the western face of the hill on which it is partly built. On the summit of this eminence stands the palace, commanding a distinct view of the town and adjacent country. That quarter of the hill on which the khan's residence is erected has been inclosed by a mud wall, with bastions; the entrance to it is on the south-western side; and here, as well as at the city gates, which are three in number, there is constantly a guard of matchlock-men. Within the walls there are upwards of 2500 houses, and the number of these in the suburbs probably exceeds one half of that amount. The houses are mostly built of half-burnt brick or wooden frames, and plastered over with mud or mortar. In general the streets are broader than those of native towns, and most of them have a raised pathway on either side for foot-passengers, and an uncovered kennel in the centre; the latter of which is a great nuisance, from the quantity of filth thrown into it, and the stagnant rain-water that lodges there. The upper stories of the houses frequently project across the streets, and thereby render the part beneath them gloomy and damp. This seems a very rude attempt to imitate the bazaars of Persia and Cabûl. The bazaar of Kelat is extensive, well furnished with every kind of goods; and all the necessaries of life may be procured daily at a moderate price. The town is supplied with delicious water from a spring in the face of a hill on the opposite side of a plain, whence it meanders nearly through its centre; having the town and suburbs on one side, and on the other the gardens. It may be remarked of this spring, that the waters, at their immediate issue from the smaller channels, possess a considerable degree of tepidity until after sunrise, when they suddenly become exceedingly cold, and remain so during the day.

Beloochistan.

Inhabitants.

We have no data from which we can form an accurate computation of the total amount of the population of Beloochistan. The inhabitants are divided into two great classes, distinguished by the appellations of Belooche and Brahooé; and these two are again subdivided into an infinite number of tribes, which it were tedious and unnecessary to enumerate. The most remarkable distinctions between these two classes consists in their language and appearance. The Belooche or Beloochekee language partakes considerably of the idiom of the modern Persian, although greatly disguised under a singularly corrupt pronunciation. The Brahooékee, on the other hand, has nothing analogous to the Persian idiom. It appears to contain a great number of ancient Hinduwee words; and, as it strikes the ear, bears a strong resemblance to the dialect spoken in the Punjaub. With regard to external appearance, the contour of these two classes seems to differ, in most instances, as much as their language. The Belooches in general have tall figures, long visages, and raised features; the Brahooés, on the contrary, have short thick bones, with round faces and flat lineaments.

Manners.

The Belooches are a handsome active race of men, not possessing great physical strength, but inured to changes of climate and season, and capable of enduring every species of fatigue. In their habits they are a pastoral people, and much addicted to predatory warfare, in the course of which they do not hesitate to commit every kind of outrage and cruelty. Notwithstanding their predatory habits, however, they are considered to be a hospitable people. After the fashion of other barbarous tribes in that part of the world, they will protect and kindly entertain a stranger while their guest, but feel no scruple in robbing and murdering him as soon as he has left their precincts. They are indolent, and, unless excited by amusement or war, or compelled to action by some urgent motive, spend their time in the manner common to all savage people—in idleness, rude dissipation, and the enjoyment of such coarse luxuries as they can procure; in lounging, gambling, smoking tobacco or hemp, and chewing opium. The tenets of their religion, and still more, perhaps, their poverty, preserve them from the abuse of fermented liquors. Their principal articles of food are milk in all its forms, the flesh of domestic animals, not ex-

Beloochistan.

cepting that of the camel, and game, including wild asses, the flesh of which is considered a delicacy. Their appetites, like those of most savages, are voracious; they consume incredible quantities of flesh when it can be obtained, and prefer it in a half-cooked state. They also use grain in the form of bread, and of various preparations; but they enjoy most such articles of food or condiment as possess a strong and stimulating flavour, as capsicum, onions, and garlic. Their indolence prompts them to keep as many slaves as they can obtain and support. Polygamy is universal. Some of the lower order have as many as eight women, either as wives or mistresses, and the number is increased in proportion to the rank and means of the man. Wives are obtained by purchase, payment being made in cattle or other articles of pastoral wealth. The ceremony of marriage is performed by the moollah or priest; and on this occasion, as well as on some others affecting females, practices similar to those of the Levitical law are observed. For instance, in this country, as also among the Afghans, a man is expected to marry the widow of a deceased brother. When a death takes place, the body is watched for three successive nights by assembled friends and neighbours, who spend their time in feasting, so that the ceremony seems intended rather to furnish enjoyment to the living than to render honour to the dead.

Dress.

The common dress of the Belooches is a coarse white or blue calico shirt, buttoned round the neck, and reaching below the knee; their trousers are made of the same cloth, or of a kind of striped stuff called Soosee, and puckered round the ankles. On their heads they wear a small silk or cotton quilted cap, fitted to the shape of the skull, over which, when in full dress, they place a turban, either checked or blue, and a *kummurbund* or sash, of the same colour, round their waists. In winter the chiefs and their relatives appear in a tunic of chintz, lined and stuffed with cotton; and the poorer classes, when out of doors, wrap themselves up in a surtout made of cloth manufactured from a mixture of goats' hair and sheep's wool. The women's dress is very similar to that of the men; their trousers are preposterously wide, and made of silk, or a mixture of silk and cotton.

Government and laws.

The fluctuation of power renders it difficult to define precisely the nature of the government of Kelat. During the reign of Nusseer Khan, the whole kingdom might be said to have been governed by a complete despotism; yet that ruler so tempered the supreme authority by the privileges granted to the feudal chiefs within their own tribes, that, to a casual observer, it bore the appearance of a military confederation. The tribes all exercise the right of selecting their own *sirdar*, or head; and the khan has the power of confirming or disapproving of their nomination; but this power is never exercised, and appears to be merely nominal. The khan of Kelat declares war and makes treaties connected with the whole of Beloochistan, and can order the sirdar of each tribe to attend in person with his quota of troops. Agreeably to a code of regulations framed by one of the earliest princes of the Kumburanee dynasty, the entire administration of justice was vested in the person at the head of the government. The sirdar, however, has the power of adjusting petty quarrels, thefts, and disputed points of every description, among the inhabitants of a kheil or society; but, in all cases of importance, an appeal lies in the last instance to the khan at Kelat.

The amount of revenue enjoyed by the khan of Kelat is inconsiderable, as the ruling races, Belooche and Brahooé, pay no direct taxes, and their poverty and simple habits prevent them from contributing much indirectly. His income is therefore derived from his resources as a proprietor of lands or towns, from a proportion of the produce paid in kind by the Afghan, Dehwar (Parsee), and Jet cultivators; from dues on direct and transit trade, and from arbitrary exactions, a never-failing mode with Eastern potentates of recruiting an exhausted treasury. Pottinger estimates the amount at 350,000 rupees; Masson, who had ample means of acquiring information through colloquial channels, at 300,000: which of these statements makes the nearest approximation to correctness cannot be determined, but neither seems improbable. With such a revenue, it is obvious that no standing army can be maintained; and Masson, certainly very competent to the task of acquiring information on this subject, states that Mehrab Khan, the late ruler, "nearly destitute of troops in his own pay, was compelled, on the slightest cause for alarm, to appeal to the tribes, who attended or otherwise as suited their whims or convenience." Pottinger computes the numbers available for the service of the khan at 60,000 fighting men, but has not mentioned how so vast a host could, if collected, find food in this barren country. Mehrab Khan could on no occasion assemble more than 12,000; and in his final struggle for property, power, and life, the number of his troops did not amount to 3000. The Belooche soldier is heavily encumbered with arms, carrying a matchlock, a spear, a sword, a dagger, and a shield. Pottinger considers them good marksmen, and states that in action they trust principally to their skill in this respect, avoiding close combat; but their readiness in general to close with the British troops shows that he is in this instance mistaken. They formed the strength of the armies of Sinde; but the battle of Meanee proves how little, even with great superiority of numbers, they are able to withstand a disciplined force. The greater part serve on foot; but a number, not inconsiderable, have horses, and, in their irregular forays, camels, which they often prefer, on account of their greater powers of endurance. (J. C.) (E. T.)

Belper || Belt.

BELPER, a market-town and chapelry of Derbyshire, in the parish of Duffield, and hundred of Appletree. The town is agreeably situated on the banks of the Derwent, which is here crossed by a handsome stone bridge. It is seven miles north of Derby, on the line of the North Midland railway. Belper, now one of the most flourishing towns of Derbyshire, is principally indebted for its prosperity to the establishment of cotton works here by Messrs Strutt. It also manufactures linens, nails, hosiery, &c. It has three churches, several chapels for Independents, Methodists, Baptists, &c., a mechanics' institution, and a subscription library. Pop. (1851) 10,082.

BELSHAM, Thomas, LL.D., for some years the principal of the Dissenters' Academy at Daventry, was born at Bedford in 1750. He abandoned Calvinism for the Unitarian theology, and proved himself in numerous publications a learned exponent of that system. In 1801 he gave to the world *Elements of the Human Mind, and of Moral Philosophy*, in which, following the doctrines of Hartley, he explained all mental operations by the association of ideas. He died at Hampstead in 1829.

Belsham, *William*, the younger brother of the preceding, was born in 1752, and died at Hammersmith in 1827. He published various political tracts in support of Whig principles, and was the author of a history of Great Britain from the accession of George I. to the peace of Amiens in 1802, in 12 vols. 8vo. His volume on the *Philosophy of the Mind* is less known.

BELSHAZZAR, the last king of Babylon, generally supposed to be the son of Evilmerodach, and grandson to Nebuchadnezzar. See Daniel, chap. v. It may be noticed that Xenophon's account (*Cyropæd.* viii. 5, 30) agrees with the Book of Daniel as to the fate of Belshazzar.

BELT, Great and Little, the name of two straits which connect the Baltic with the Cattegat. The former lies between the islands of Zealand and Funen. Its greatest width is about twenty miles, and its depth varies from five to twenty fathoms. The navigation of the Great Belt is dangerous, from the number of sand-banks and small islands which it

Belt || Belzoni.

contains. The shores in general are neither bold nor lofty, but they afford convenient harbours and anchorage. Vessels passing this strait pay toll at Nyborg, where a guard-ship is stationed to enforce compliance. The Little Belt separates the island of Funen from Jutland. Its greatest breadth is not more than the half of that of the Great Belt, and at the fortress of Fredericia, where the tolls are levied, it does not exceed a mile. The depth is from four to twenty fathoms. It contains several sand-banks, and the current from the Baltic to the Cattegat is of great strength. The passage of both Belts is attended with risk for large vessels, and on that account the Sound is more generally frequented.

BELT, *Balteus*, properly denotes a kind of military girdle or cincture, usually of leather, by which the sword or any other weapon is sustained. The belt was an essential piece of the ancient armour; insomuch that we sometimes find it used to denote the whole armour. In later ages the belt was given to a person when he was raised to knighthood; and hence it has also been used as a badge or mark of the knightly order.

BELTS, in *Astronomy*. See ASTRONOMY.

BEL-TEIN, or BEL-TANE, a superstitious custom formerly observed in the Highlands of Scotland, being a kind of rural sacrifice, performed by the herdsmen on the 1st of May. It seems to have been a remnant of some Oriental superstition relative to the worship of Baal or the Sun, and derived from Druidical times. Some account of this festival may be found in Pennant's *Tour*, General Stewart's *Sketches*, and in almost every work which treats of the Highlands. The Beltane of the Irish is celebrated on the 21st of June.

BELTURBET, a town of Ireland, in the county of Cavan, on the river Erne, 77 miles N.W. of Dublin. A corn-market is held here weekly. Pop. (1851) 2054.

BELUNUM, in *Ancient Geography*, a considerable town of Rhætia, about twenty miles N.E. of Feltria, in the territory of the Veneti; now *Belluno*.

BELUS, now *Nahr Naman*, a small river of Phœnicia, which enters the sea close to Acre, the ancient Ptolemais. Here the discovery of the manufacture of glass is said to have been accidentally made by some shipwrecked mariners who kindled a fire on its banks. See Pliny, xxxvi. 26. Reland conjectures that the name Βηλεύς may be the origin of the Greek ὕέλος or ὕαλός, *glass*.

BELVEDERE, in *Italian Architecture*, denotes a pavilion on the top of a building, or an artificial eminence in a garden. The word signifies a *fine prospect*.

BELVEDERE, a town of Naples, in the province of Calabria Citra, on the Mediterranean, 32 miles N.W. of Cosenza. Pop. 4000.

BELZONI, GIOVANNI BATTISTA, the well-known traveller, was born of humble parentage at Padua, about 1778. Much of his early youth was passed at Rome, with an intention of adopting the monastic life; but from this plan he was diverted by the French invasion. He came to England in 1803; and for some time obtained a livelihood as an athlete at Astley's amphitheatre and elsewhere, for which his colossal stature and extraordinary muscular power eminently qualified him. While residing at Rome he had paid considerable attention to the study of hydraulics, and with the view of constructing improved machines for the purposes of irrigation, he went in 1815 to Egypt, where he was employed by the pacha to construct an hydraulic machine for his garden at Zubra, near Cairo, which, however, proved an unsuccessful attempt. He was then employed by Mr Salt to remove the colossal bust erroneously styled the "Young Memnon." This he effected with much ingenuity, and shipped it for England. Pursuing his travels through Egypt, he was the first to open the temple of Ipsambul, an undertaking involving extraordinary personal exertion. During a second journey in Upper Egypt he made excavations at Carnac, which well repaid his labours. It is unnecessary here to recount his various and most interesting discoveries, as they are detailed at some length in the articles EGYPT, NUBIA, &c. In 1820 he published a narrative of his operations; and in the following year he exhibited at London a beautiful model of the two principal chambers of the magnificent tomb he had opened at Beban-el-Molouk, near Thebes. In 1823 he again visited Egypt; but while making preparations for passing from Benin to Timbuctoo, he was attacked by dysentery at a place called Gato, and there he died on the 3d of December.

Bem || Benares.

BEM, JOSEPH, a distinguished general in the Hungarian war of 1848, was born in Poland, of German parents, in 1795. He died in exile at Aleppo in December 1850. See HUNGARY.

BEMBEA. See BAMBA.

BEMBO, PIETRO, *Cardinal*, a noble Venetian, secretary to Leo X., and one of the best writers of that illustrious age. He was a good poet, both in Italian and Latin; but he is justly censured for the licentiousness and immodesty of some of his poems. Besides these, he published *A History of Venice; Letters;* and a book in praise of the Duke and Duchess of Urbino. He died in 1547, in the seventy-seventh year of his age. His collected works and life were published at Venice in 1729, in 4 vols. folio.

BEN or BEINN, a Gaelic word signifying a mountain. Hence the names Ben-Nevis, Ben-Macdhui, &c.

BENACUS LACUS, the ancient name of the Lago di Garda.

BENARES, a British district of Hindustan, situate on both sides of the river Ganges, in the territory denominated the North-West Provinces of Bengal. It lies between Lat. 25. 7. and 25. 32. Long. 82. 45. and 83. 38., and has an area of 994 square miles. The principal commercial products of the district are sugar, opium, and indigo. According to the census of 1848 the population amounts to 741,426, of whom 676,050 are Hindus, and 65,376 Mussulmans. The total number of towns has been returned at 1888; of these 1818 contain each less than 1000 inhabitants; 67 have each more than 1000 and less than 5000 inhabitants; two are stated each to have more than 5000 and less than 10,000; and one alone contains more than 50,000 inhabitants. The territory was ceded to the East India Company in 1775 by the vizier of Oude.

BENARES, an extensive and opulent city of Hindustan, in the province of Allahabad, is the capital of the Benares district. It has long been celebrated among the Hindus as a seat of piety and learning, as well as a noted emporium of trade. The Ganges here forms a fine sweep of about four miles in length, and the city is situated on the northern bank of the river, and on the outward side of the curve, which is the most elevated. It is about three miles in length by one in breadth, rising from the river in the form of an amphitheatre, and is thickly studded with domes and minarets. The bank of the river is entirely lined with stone, in which are many very fine ghats or landing-places, built by pious devotees, of large stones, to the height of thirty feet before they reach the level of the street, and highly ornamented. These are generally crowded with bathers and worshippers. Shrines and temples, even within the limits of the river's rise, almost line its banks. The streets of this great city are so winding and narrow that there is not room for a wheel-carriage to pass; and it is difficult to penetrate them even on horseback. The streets are considerably lower than the ground-floors of the houses, which have mostly arched rows in front, with little shops behind them; and above these they are richly embellished with verandahs, galleries, projecting oriel windows, and very broad overhanging eaves supported by carved brackets. The houses are built of a very good stone from Chunar, and are mostly lofty, none being less than two stories in height, most of them three, and several of five or six stories, close to each other, with terraces on the summit, and extremely small windows, for the sake alike of coolness and of privacy. The Hindus are fond of painting the

Benares.

outside of their houses of a deep red colour, and of covering the most conspicuous parts with paintings in gaudy colours of flower-pots, men, women, bulls, elephants, gods, and goddesses, in all the forms of Hindu mythology. The number of temples is very great; they are mostly small, and stuck in the angles of the streets, and under the shadow of the lofty houses. Their forms are not ungraceful, and many of them are covered over with beautiful and elaborate carvings of flowers, animals, and palm branches, rivalling in richness and minuteness the finest specimens of Gothic or of Grecian architecture.

The mosque, which was built by Aurungzebe on the site of a Hindu temple, and in order to mortify the Hindus, is a handsome building, placed on the highest and most conspicuous point of land, and close to the river. Its minarets are very lofty, and command an extensive view of the town and adjacent country, and of the numerous Hindu temples scattered over the city and the surrounding plains. The Sanscrit College, instituted in 1792, is a large building divided into two courts with galleries above and below. An English department has been attached to this college. In 1850 the number of pupils amounted to 240; of whom six were native Christians, sixteen Mahometans, and 218 Hindus. The course of instruction embraces Sanscrit, Persian, Hindu law, and general literature. In this city a new government college has been recently established, in which the whole range of European literature and science is thrown open to the native student.

Benares, having from time immemorial been a holy city, contains a vast number of Brahmins who either subsist by charitable contributions or are supported by endowments in the numerous religious institutions of the city. These establishments are adorned with idols, and send out an unceasing sound from all sorts of discordant instruments; while religious mendicants from the numerous Hindu sects, with every conceivable deformity "which chalk, cow-dung, disease, matted locks, distorted limbs, and disgusting and hideous attitudes of penance, can show, literally line the principal streets on both sides." Some are seen with their legs or arms distorted by long continuance in one position; others with their hands clenched until the finger-nails have pierced entirely through the hand. A stranger, as he passes through the streets, is saluted with the most pitiful exclamations from these swarms of beggars. But besides this immense resort to Benares of poor pilgrims from every part of India, as well as from Thibet and the Burman empire, numerous rich individuals in the decline of life, and almost all the great men who are disgraced or banished from home by the political revolutions which have been of late years so frequent among the Hindu states, repair to this holy city to wash away their sins in the sacred waters of the Ganges, or to fill up their time with the gaudy ceremonies of their religion. All these devotees give away large sums in indiscriminate charity, some of them to the annual amount of L.8000 or L.9000; and it is the hope of sharing in these pious distributions that brings together from all quarters such a concourse of religious mendicants. Bulls are reckoned sacred by the Hindu, and being tame and familiar, they walk lazily up and down the streets, or are seen lying across them, interrupting the passage, and are hardly to be roused, as, in compliance with the prejudices of the fanatic population, they must be treated in the gentlest manner. Monkeys, also held sacred, are seen clinging to all the roofs and projections of the temple.

But, amid all this wretchedness and fanaticism, Benares is a splendid, wealthy, and commercial city; the bazaars are filled with the richest goods, and there is a constant bustle of business in all the principal streets. It is a great commercial emporium for the shawls of the north, the diamonds of the south, and the muslins of Dacca and the eastern provinces; and it has very considerable manufactures of silk, cotton, and fine wool, as well as of gold and silver lace; while English hardware, swords, shields, and spears from Lucknow and Monghyr, and the finer manufactures of Europe, are exported to Bundelcund, Gorruckpoor, Nepaul, and other tracts removed from the main channel of communication by the Ganges. The population of the city and suburbs, exclusive of the military cantonment, is returned at 183,491, of which number 147,082 are Hindus, and 36,409 Mahometans; and during religious festivals, the concourse of people from all parts is immense. Yet the city, notwithstanding its crowded population and narrow streets (the new market-place, constructed by the present government, being the only square or open part in it), is not unhealthy; which is probably owing to its dry situation on a high rocky bank, sloping towards the river, and to the frequent ablutions and temperate habits of the people. There are but few Europeans in Benares; a judge, collector, and register, with a few other civil servants, constitute the whole of the Company's establishment; to which may be added a few private merchants and planters. The residence of the English judge and civil establishment is at Secrole, a pleasant village about two miles from the city, where there is a military cantonment for a battalion of sepoys. Distant N.W. from Calcutta 420 miles; from Allahabad E. 74; from Delhi S.E. 466; Lat. 25. 17. Long. 83. 4. (D. B.—N) (E. T.)

Benavidius || Bench.

BENAVIDIUS, or BONAVIDUS, *Marcus Mantua*, a celebrated civilian, who during sixty years taught civil law with high reputation at Padua, the place of his birth. He died in 1582, aged ninety-three.

BENBECULA, a low, sandy, and unproductive island of the Hebrides, eight miles in length, and the same in breadth. It is situated between the islands of North and South Uist, from the latter of which it is separated by a narrow channel. It forms part of the county of Inverness.

BENCH, or BANC, in *Law*, has various significations.

Free-Bench signifies that estate in copyhold-lands which the wife, being espoused a virgin, has, after the decease of her husband, for her dower, *dum sola et casta fuerit*, according to the custom of the manor. With respect to this free-bench, different manors have different customs.

Queen's Bench, a court in which the sovereign was formerly accustomed to sit in person. It is called the King's Bench in the reign of a king, and was styled the Upper Bench during Cromwell's protectorate. This was originally the only court in Westminster Hall, being styled *Aula Regia*, and from it the courts of Common Pleas and Exchequer are supposed to have been derived. As the sovereign in person is still presumed in law to sit in this court, though only represented by the judges, it is said to have supreme authority; and the proceedings in it are supposed to be *coram nobis*, that is, before the sovereign. This court consists of a lord chief justice and four other judges, or *puisné* justices, the former appointed by writ, the latter by patent, who are, according to Sir William Blackstone, "by their office the sovereign conservators of the peace, and supreme coroners of the land." They hold their offices *quamdiu se bene gesserint*, and in case of misconduct are removable only by address of both houses of parliament. By the 2d and 3d Will. IV. cap. 116, and 14th and 15th Vict. cap. 41, the chief justice receives a salary of L.8000, and the other judges of L.5000 each, with an allowance of L.40 a year to the senior.

"The jurisdiction of this court," observes Mr Justice Blackstone, "is very high and transcendent. It keeps all inferior jurisdictions within the bounds of their authority, and may either remove their proceedings to be determined here, or prohibit their progress below. It superintends all civil corporations in the kingdom, and commands magistrates and others to do what their duty requires in every case where there is no other specific remedy. It protects the liberty of the subject by speedy and summary interposition." It takes cognisance both of civil and criminal causes: its jurisdiction on the plea side or civil branch embracing all actions

Bench || Bends.

between subject and subject, excepting only those of the real class and matters of revenue, and extending throughout the entire realm of England, the principality of Wales, and the town of Berwick-on-Tweed; and on the crown side or crown office, it includes all criminal causes from high treason down to the most trivial breach of the peace, and whether against the public good or to the injury of any particular person. Nor can any private subject suffer unlawful violence or injury against his person, liberty, or possessions, without a proper remedy being afforded him here, not only for satisfaction of damages sustained, but for the punishment of the offender; and wherever this court meets with an offence contrary to the first principles of justice, it may punish it by its own authority. Persons illegally committed to prison, though by the king and council, or by either house of parliament, may be bailed in it, and in some cases even upon legal commitments. Writs of mandamus are issued by this court, for the restoring of officers in corporations unjustly turned out, freemen wrongfully disfranchised, and in a variety of other cases. Into this court also indictments from all inferior courts may be removed by writ of *certiorari*, and tried either at bar or at *nisi prius*. Error lies from this court to the court of Exchequer Chamber, under the 11th Geo. IV., and 1st Will. IV. cap. 70.

The officers on the crown side are, under the 6th and 7th Vict. cap. 20, "the queen's coroner and attorney, one master, and one assistant-master." On the side of the pleas there are five masters and the following clerks: four to the masters, six in the rule department, three in the writ department, four in the judgment department, three in the appearance department, two in the treasury department, one in the error and outlawry departments; to which may be added, the marshal and associate to the chief justice, comptroller of judges' fees, three ushers, three tipstaffs, train bearer, crier at *nisi prius*, and body clerk. (R. M—M.)

Common Bench. See Common Pleas, Court of.

BENCHERS, in the inns of court, the senior members of the society, who are invested with the government of the body to which they belong.

BENCOOLEN, formerly the chief establishment possessed by the East India Company in the island of Sumatra, on the south-western coast. It was for a few years a distinct presidency. In 1719 the settlers were expelled by the natives, but were soon permitted to return. In 1760 all the English settlements on the coast of Sumatra were destroyed by a French fleet under Comte d'Estaign. They were afterwards re-established and secured to the British by the treaty of 1763; but in 1825 they were finally ceded to the king of the Netherlands in exchange for the Dutch settlements on the continent of India. Long. 102. 3. E. Lat. 3. 50. S.

BEND, in *Heraldry*, one of the nine honourable ordinaries, containing a third part of the field when charged, and a fifth when plain.

BENDER, a town of Bessarabia in European Russia, seated on the river Dniester, 48 miles from its mouth. It is inclosed by a wall and ditch, and has a citadel, with about 10,000 inhabitants. It was stormed and taken by the Russians in 1770, and again in 1809, and finally ceded to them by the treaty of Bucharest in 1812. In the vicinity is Varnitza, the retreat of Charles XII. after the battle of Pultowa. Long. 29. 36. E. Lat. 46. 50. 32. N.

BENDIDEIA, a festival celebrated by the Athenians in honour of Bendis, a Thracian divinity, whom they identified with their own Artemis. This festival bore much resemblance to those of Dionysus.

BENDING, in nautical language, the tying of two ropes or cables together; thus, to *bend the cable*, is to make it fast to the ring of the anchor; to *bend the sail*, to make it fast to the yard.

BENDS, in a ship, more generally called *wales*, are the thickest and stoutest planks in her side, on which men set their feet when climbing up. They form the chief strength of a ship's sides, and have the beams, knees, and foot-hooks, bolted to them.

Bendy || Benedictines.

BENDY, in *Heraldry*, is the field divided into four, six, or more parts, diagonally, varying in metal and colour.

BENE, a city of the province of Mondovi, in the kingdom of Sardinia. It stands on a hill between the rivers Sturo and Tanaro, 18 miles N.E. of Cuneo, and contains several churches and other religious houses. Pop. 6000.

BENEDICITE, among ecclesiastical writers, an appellation given to the song of the three children in the fiery furnace, on account of its beginning with the word *benedicite*. The use of this song in Christian worship is very ancient, having been sung in all the churches as early as the time of St Chrysostom.

BENEDICT, St, the founder of the order of the Benedictine monks, was born in Italy about A.D. 480. He received the first part of his education at Rome; and at fourteen years of age he removed to Sublaco (Subiaco), about thirty miles distant. Here he lived an ascetic life, shut up in a cavern, where nobody knew anything of him except St Romanus, who used to descend to him by a rope, and supply him with food. Being afterwards discovered by the monks of a neighbouring monastery, they chose him for their abbot; but as their manners were not in accordance with his own, he returned to his solitude. Many persons followed him and put themselves under his direction; so that in a short time he was enabled to build twelve monasteries. In the year 528 or 529 he retired to Monte Cassino, where idolatry was still prevalent, a temple of Apollo having been erected there. He instructed the people in the adjacent country, and, having converted them, broke in pieces the image of Apollo, and built two chapels on the mountain. Here he also founded a monastery, and instituted the order of his name, which in time became so famous, and extended itself all over Europe. In this place, too, he composed his *Regula Monachorum*, which Gregory the Great speaks of as the most sensible and best written piece of the kind ever published. The period of his death is uncertain. He was looked upon as the Elisha of his time, and is reported to have wrought a great number of miracles, which are recorded in the second book of the Dialogues of St Gregory the Great.

Benedict, abbot of Peterborough, an ancient English historian. He was educated at Oxford, became a monk in the monastery of Christ Church in Canterbury, and was some time afterwards chosen prior by the members of that society. Although a great admirer and the biographer of Thomas à Becket, he was so much esteemed by Henry II. that, by the influence of that prince, he was elected abbot of Peterborough A.D. 1177. He assisted at the coronation of Richard I. in 1189, and was appointed keeper of the great seal in 1191. He died on Michaelmas day 1193. He wrote, besides his life of à Becket, a history of Henry II. and Richard I., from 1170 to 1192, which was published at Oxford by Hearne in 1735, 2 vols. 8vo.

Benedict XIV., Pope (Prosper Lambertini), was born of an illustrious family, at Bologna, in 1675. He was celebrated for his learning, moderation, and exemplary life, which gained him the esteem even of Protestants. He greatly patronized learned men and celebrated artists, and was an elaborate writer on theological subjects. His works fill 16 vols. 4to. He succeeded Clement XII. in 1740, and died in 1758, at the age of eighty-three.

BENEDICTINES, an order of monks who profess to follow the rules of St Benedict. The Benedictines, who of all the regular clergy are alone entitled to the appellation of *monks*, wear a loose black gown with large wide sleeves, and on their heads a capuche or cowl ending in a point behind. In the canon law they are styled *black friars*, from the colour of their habit.

Benedic-tion.

The rules of St Benedict, as observed by the English monks before the dissolution of the monasteries, were as follows: The monks of this order were obliged to perform, seven times in twenty-four hours, their devotions, the whole circle of which had reference to the passion and death of Christ; they always went two and two together; every day in Lent they fasted till six in the evening, and abated of their usual time of sleeping and eating, but they were not allowed to practise any voluntary austerity without leave of their superior; they never conversed in their refectory at meals, but were obliged to attend to the reading of the Scriptures; and they all slept in the same dormitory, in separate beds, and lay in their clothes. For small faults they were shut out from meals, for greater they were debarred religious commerce and excluded from the chapel; and incorrigible offenders were excluded from the monasteries. Every monk had two coats, two cowls, a table-book, a knife, a needle, and a handkerchief. The furniture of their cells was a mat, a blanket, a rug, and a pillow.

In the year 596 Pope Gregory sent into England Augustin, prior of the monastery of St Andrew at Rome, with several other Benedictine monks; to whom the English owe their conversion from idolatry. Augustin became archbishop of Canterbury, and the Benedictines founded several monasteries in England, besides the metropolitan church of Canterbury, and other cathedrals.

Pope John XXII., who died in 1334, found, after an exact inquiry, that, since the rise of the order, it had produced 24 popes, nearly 200 cardinals, 7000 archbishops, 15,000 bishops, 15,000 abbots, and above 4000 saints, besides founding upwards of 37,000 monasteries. There have been likewise of this order 20 emperors and 10 empresses, 47 kings, and above 50 queens, 20 sons of emperors and 48 sons of kings, above 100 princesses, daughters of kings and emperors, besides dukes, marquises, earls, countesses, &c., innumerable. The order has produced an immense number of eminent writers and learned men. Rabanus set up the school of Germany; Alcuinus founded the university of Paris; Dionysius Exiguus perfected the ecclesiastical computation; Guido invented the scale of music, Sylvester the organ; and they boast of having produced Anselm, Ildephonsus, Venerable Bede, and many others of equal or superior name. There are nuns likewise who follow the rule of St Benedict.

BENEDICTION, in a general sense, the act of blessing, or giving praise to God, or returning thanks for his favours. Neither the ancient Jews nor the early Christians ever ate without a short prayer. The Jews are obliged to rehearse a hundred benedictions a-day; of which eighty are to be spoken in the morning. The first treatise of the first order in the Talmud, entitled *Seraim*, contains the form and order of the daily benedictions. Benedictions were likewise given among the ancient Jews, as well as Christians, by the imposition of hands. When at length the primitive simplicity of the Christian worship became corrupted by ceremony, they added the sign of the cross. The custom of receiving benediction by bowing the head before the bishops, is very ancient; and even emperors did not decline this mark of submission.

BENEDICTION is also used for an ecclesiastical ceremony, whereby a thing is rendered sacred or venerable. In this sense benediction differs from consecration, as in the latter unction is applied, but not in the former. Thus the chalice is consecrated, and the pix blessed, as the former, not the latter, is anointed; but in common usage these two words are applied promiscuously.

Beatic BENEDICTION, *Benedictio beatica*, is the viaticum given to dying persons.

Nuptial BENEDICTION, the external ceremony performed by the priest in the office of matrimony. The nuptial benediction is not essential to, but the confirmation of, a marriage in the civil law.

Benefice.

BENEFICE was applied by the old Romans to the portions of lands obtained by conquest and given to the soldiers as rewards or *beneficia* for past services, and as an encouragement to future exertions. Hence in time it became applicable to the portions of land granted under the feudal system by a lord to his vassal for maintenance, and as a stipendiary return for military services which they were expected to render. In this sense, a benefice was an estate in land, at first granted for life only, and so called because it was held *ex mero beneficio* of the donor; and the tenants were bound to swear fealty to their lord, and to serve him in the wars. In aftertimes, as these tenures became perpetual and hereditary, the name of *beneficia* was transferred to the livings of the clergy, and that of *feuda* assumed.

According to Duarenus, its strict and proper interpretation is "an ecclesiastical estate which is granted to some priest or clergyman for term of life, to be enjoyed by him on the account of his ministry in the church." But in the various statutes relating to church matters the term is expressly defined. Under the 12th section of the 1st and 2d Vict. cap. 106, and section 3 of the Amendment Act, 14th and 15th Vict. cap. 98 (as to the holding of benefices in *plurality*), the word is to be understood to mean a "benefice with cure of souls," and therein to comprehend "all parishes, perpetual curacies, donatives, endowed public chapels, parochial chapelries, and chapelries or districts belonging or reputed to belong, or annexed or reputed to be annexed, to any church or chapel."

Under the 2d and 3d Vict. cap. 49, sec. 21 (relating to the assignment of districts to churches augmented by Queen Anne's Bounty), it extends to "all rectories with cure of souls, vicarages, perpetual curacies, and chapelries, the incumbents of which respectively shall, in right thereof, be corporations sole."

Under the 5th and 6th Vict. cap. 27, sec. 15, and 5th and 6th Vict. cap. 108, sec. 31 (as to the grant of farming leases, and leases for long term of years), it comprehends "every rectory, vicarage, perpetual curacy, donative, endowed public chapel, parochial chapelry, and district chapelry, the incumbent of which, in respect thereof, shall be a corporation sole."

According to the canons of the Church of England, a benefice cannot be taken without the bishop's consent, nor be divided; and any division is decreed null, nor is it to be given on the bare report of the death of the incumbent, nor to be promised while full, nor to be seized by violence, nor to be farmed to a layman, unless to a clerk who shall be fully instituted as general procurator for the time agreed; and under the 1st and 2d Vict. cap. 106, sec. 108, benefices, so far as pluralities and residence are concerned, are subject to the jurisdiction of the archbishop or bishop within whose province or diocese they are locally situate.

The following requisites are indispensable in order to be legally entitled to a benefice: 1. Presentation, nomination, or collation; 2. Examination as to ability, &c., by the bishop; 3. Institution or collation, after taking the oaths against simony, of allegiance and supremacy, of canonical obedience, and by subscribing the three articles concerning the supremacy, the Common Prayer and the Thirty-nine Articles, and the declaration of conformity; 4. Induction; 5. Reading the Common Prayer, the Thirty-nine Articles, and declaration of assent thereto, together with the ordinary's certificate of subscription to the declaration of conformity; and, 6. Taking the oaths of allegiance, supremacy, and abjuration at the sessions.

An avoidance of a benefice takes place—1. By death; 2. By resignation; 3. By cession, or the acceptance of a benefice incompatible therewith; 4. By deprivation under a sentence in the ecclesiastical court; 5. By act of law, for simony, non-subscription of articles, &c.; and, 6. By non-compliance with the requisites.

Benefice || Bengal.

By the returns for the year 1850 made to Her Majesty in council by the respective archbishops and bishops, there were in the dioceses of England and Wales—

Total number of benefices in which the incumbents were resident, ...	8077
Total number of benefices in which the incumbents were non-resident, ...	2952
Miscellaneous cases, ...	699
Total,	11,728
Total number of benefices on which there is a glebe-house, ...	8214

Of these 11 are under L.10; 19 from L.10 to L.20; 32 from L.20 to L.30; 235 from L.30 to L.50; 1629 from L.50 to L.100; 1602 from L.100 to L.150; 1354 from L.150 to L.200; 1979 from L.200 to L.300; 1326 from L.300 to L.400; 830 from L.400 to L.500; 954 from L.500 to L.750; 323 from L.750 to L.1000; 134 from L.1000 to L.1500; 32 from L.1500 to 2000; 16 of L.2000 and upwards. Among the last-mentioned is the rectory of Stanhope, in the county of Northumberland, of the annual value of L.4843; and the rectory of Doddington, in the county of Cambridge, worth L.7306 a-year.

Benefice in commendam (*ecclesia commendata*) is, according to Godolphin, an ecclesiastical living which, being void, is commended to the charge and care of some sufficient clerk, to be supplied until it may be conveniently provided with a pastor; the person to whom the church is thus commended having the fruits and profits thereof only for a certain time. The law relating to this subject has, however, been abolished by the 6th and 7th Will. IV. cap. 77, sec. 18, which enacts that no ecclesiastical dignity, office, or benefice, shall be held in *commendam* by any bishop, unless he held the same at the time of the passing of the act, and every *commendam* thereafter granted, whether to retain or to receive, and whether temporary or perpetual, is declared to be absolutely void to all intents and purposes.

BENEFICIARII, in *Roman Antiquity*, those who were promoted on account of their merits, or exempted by special favour from ordinary military service. The term was likewise applied to such as were discharged from the military service, and provided with *beneficia* or pensions. They were sometimes called upon to do military service as volunteers, when they were denominated *evocati*. Before their recall they were styled *emeriti*.

Beneficiary || Bengal.

The word *beneficiarius* frequently occurs in the Roman inscriptions found in Britain, where *consulis* is always joined with it; but besides *beneficiarius consulis*, we find in Gruter *beneficiarius tribuni, prætorii, legati, præfecti, proconsulis*, and such like expressions.

BENEFICIARY, *Beneficiarius*, one who holds a benefice. A beneficiary is not the proprietor of the revenues of his church; he has only the administration of them, though not accountable for his conduct therein to any but God and his superior.

This term is applied by the writers of the middle ages to a feudatory or vassal; and also to the clerks or officers who kept the accounts of the *beneficia*.

BENEFIELD, Sebastian, a very eminent divine, born in 1559, at Prestonbury in Gloucestershire, and educated at Corpus Christi College, Oxford. In 1613 he was chosen Margaret professor in that university; which appointment he held with great reputation till 1626, when he resigned it and retired to his rectory of Meysey-Hampton, in Gloucestershire. He published commentaries upon the first, second, and third chapters of Amos; a considerable number of sermons; and some Latin treatises. He died in 1630.

BENEFIT of Clergy. See Clergy.

BENEFIT Societies. See Friendly Societies.

BENEVENTO, a city of Italy, capital of a small delegation of the same name, which belongs to the States of the Church, and is bounded by the Neapolitan province of Principato Ultra. The town is surrounded by walls and defended by a castle. It is situated on a hill near the confluence of the Calore and the Sabato, 32 miles N.E. of Naples. It occupies the site of the ancient Beneventum, and is almost entirely built of the ruins of that town. Except Rome, perhaps no city can boast of so many remains of antiquity. Of these the most beautiful and perfect is the Arch of Trajan, 52 feet in height, consisting of a single arch of Parian marble of the Corinthian order, highly ornamented with basso and mezzo rilievos. See Serlio, *Architettura*. It is the see of an archbishop, and has a cathedral, several churches, a town-hall, diocesan seminary and library, and several hospitals. Pop. of delegation (1843) 23,910; of city 17,500.

B E N G A L,

Boundaries

The largest and most important division of Hindustan, situate towards its eastern extremity, and containing Calcutta, the seat of the British government in India. Excluding the possessions of the native princes, over which the British government merely exercises political supremacy, and excluding also the Punjab and the Agra, or north-western provinces, which are administered by functionaries having the powers and authority of lieutenant-governors, the tract embraced within the presidency of Bengal lies between the 10th and the 28th degrees of north latitude, and between the 83d and 99th degrees of east longitude. Its most northern extremity is situate in the province of Assam, and its most southern point lies on the coast of Tenasserim. The district of Mirzapore, under the jurisdiction of the lieutenant-governor of Agra, forms the extreme boundary on the west, and the frontier of Siam constitutes its most eastern limit. The longest line which could be drawn with extremities lying within the limits of the presidency, is that in a direction from S.E. to N.W., from the Pak Chan river in Tenasserim to the north-western angle of the district of Sarun, where the river Gunduck issues from the mountains of Nepaul, in Lat. 27. 25. Long. 83. 55., and would measure about 1550 miles in length. A considerable part of this line would, however, lie across the Bay of Bengal. The longest line that could be drawn without crossing the bay is from N.E. to S.W., from the boundary of Assam to that of the British district of Palamow, a distance of about 870 miles. The extreme breadth of the presidency, measured at right angles to this last-stated line, is about 465 miles, bearing from S.E. to N.W., from the mouth of the Hooghly to the exit of the Gunduck from the mountains of Nepaul. The area of the presidency, as thus defined, amounts to 225,103 square miles.

Aspect of the country.

Bengal, especially as it approaches the sea, may be designated a level country. Even in its northern frontier, it is reached only on one point by any of the branches that diverge from the Himalayas. A spur from the great culminating range bounds the north-eastern extremity of Assam; and thence taking a southerly direction through the native states of Munneepore and independent Tipperah, forms the eastern frontier of the British district of Chittagong. Continuing from this point its southerly course, it stretches, under the name of the Yoomadoung Mountains, through the province of Arracan to its southernmost point at Cape Negrais, forming the western boundary of the valley of the Irrawaddy. This spur where it touches upon Assam attains an elevation of 14,540 feet above the level of the sea, and there its summit is covered with perennial snow.

Bengal. At the Blue Mountain, in the latitude of Chittagong, it rises to the height of 8000 feet; but, with these exceptions, the general elevation of the ridge ranges between 3000 and 4000 feet. Westward of this ridge, the northern frontier of Bengal is bounded by the Sub-Himalaya Mountains, of no great elevation. Separated from these subordinate ranges by the valley of the Ganges, is the eastern extremity of the tropical zone, crossing the continent of India from west to east, and known as the Vindhya range. In its approach towards Bengal, this mountainous tract expands into several parallel ranges, some of which, stretching into the British districts of Palamow, Ramghur, Chota, Nagpore, and the northern part of Orissa, hem in the presidency on its western frontier. The area thus circumscribed by mountains is, as before observed, a level country. The Ganges, which enters on the western frontier, and runs diagonally across Bengal, gives to the country its peculiar character and aspect. About 200 miles from its mouth it spreads out into numerous branches, forming a large delta composed, where it borders on the sea, of a labyrinth of creeks and rivers named the Sunderbunds, and exhibiting during the annual inundation the appearance of an immense sea. At this time the rice-fields to the extent of some hundreds of miles are submerged, and are navigated by boats of various sizes and shapes, many of them handsome, and fitted both for commerce and for state. The scene presents to a European eye many objects of singular novelty and interest; namely, the fields covered with water to a great depth, with ears of rice floating on the surface; the stupendous dikes, which restrain, without altogether preventing, the excesses of the inundations; and peasants, in all quarters, repairing to the markets, and even to the fields, with their families and their domestic animals, in the fear that the swelling waters may sweep away their habitations, with all that they contain, in the absence of their boats. The many navigable streams which fall into the Ganges intersect the country in every direction, and afford a wonderful facility of internal communication. In most parts boats can approach, by means of lakes, rivulets, and water-courses, to the door of almost every cottage; and even in the driest season there is scarcely any spot twenty miles distant from a navigable river. The lower region of the Ganges is the richest and most productive portion of Bengal, abounding in valuable produce. Another mighty river by which Bengal is intersected is the Brahmapootra, the source of whose remotest tributary is on the opposite side of the same mountains that give rise to the Ganges. These two rivers,—which, from the contiguity of their sources, and their resemblance in length of course and bulk, have been termed sisters and rivals,—proceed in opposite courses until they are more than 1200 miles asunder; and again approaching each other, intermix their waters before they reach the ocean. The other principal rivers in Bengal are the Gogra, Sone, Gunduck, Coosy, Teesta; the Hooghly, formed by the junction of the Bhagrattee and Jellinghee; and farther to the west, the Dammoodah and the Mahanuddy. In a level country such as Bengal, where the soil is composed of yielding and loose materials, the courses of the rivers are continually shifting, from the wearing down of their different banks, and also from the water being turned off, by obstacles in its course, into a different channel. As this channel is gradually widened, the old bed of the river is left dry. The new channel into which the river flows is of course so much land lost, while the old one constitutes an accession to the adjacent estate. Thus one man's property is diminished, while that of another is enlarged or improved. Rules applicable to such contingencies are accordingly in operation, under which the land-tax is subject to increase or diminution in proportion to the quantity of land lost or acquired.

Climate. The position of Bengal brings it within the range of the tropical heats; and the year is distinguished into three seasons, the cold, the hot, and the rainy. The cold season begins in October, when the rains cease. During the succeeding four months the temperature is mild and agreeable, Fahrenheit's thermometer falling frequently to 70°. The spring and the dry season then succeed, and continue for four months, during which the heat continues progressively to increase, until it becomes almost intolerable to the natives themselves, the thermometer in the shade rising to 100°. In the beginning of April, occasional thunder-storms in the middle and south-eastern parts of Bengal, with rain or hail driven by sudden tempests of north-west wind, temper the immoderate heat. In the eastern districts, mild and refreshing showers of rain are still more frequent; but towards the west, in the country contiguous to Bahar, a parching west wind prevails in the day-time during the greater part of the hot season; night, however, bringing a cooling breeze from the opposite quarter. These west winds sometimes gives place to easterly gales which continue for days and weeks. The southerly and northerly winds, which alternately prevail in the Bay of Bengal during the summer and the winter, extend their influence over that part of the flat country which faces the bay, until they are diverted in their progress up the country by mountains corresponding with the course of the Ganges. About the beginning of June, the south-west monsoon, with thunder and lightning that seem to rend the sky, ushers in the periodical rains which refresh the atmosphere and the parched earth. The rains continue for four months, when all the rivers are in flood; and in the latter part of this season, in September, if the rains break up early, the weather is extremely close and sultry, and the inhabitants, especially the Europeans, suffer from sickness. Fogs are frequent during the dry months; and dews continue copious and refreshing, greatly assisting vegetation, as they afford nearly as large a supply of moisture as the loose soil of the country appears to require. These heavy dews are supposed to be no more than sufficient to compensate for the daily evaporation by the sun during the dry season, and so far to contribute to salubrity. The damp of the climate is ascribed to the natural want of any general system of drainage in a level country, to the luxuriant vegetation, and to the denseness of the woods, which obstruct the free circulation of the air, and retain an undue quantity of moisture amid decayed leaves and other putrid vegetable substances. This is found in all countries to be a fertile source of disease; and there is little doubt that the clearing of the forests, and a judicious system of drainage, would be followed in Bengal, as in all other parts, by a decided improvement in the climate.

Bengal.

Soil and produce. The soil of so extensive a province varies, of course, in its character and fertility with the physical peculiarities of the country. In the level tract interlaced by the Ganges and Brahmapootra, with their numerous branches and tributaries, the soil is alluvial, its basis being composed of sand, on which are annually deposited, by the retiring waters, clay, calcareous matter, and other fertilizing substances. In the tracts which lie beyond the reach of inundation, it is marked by different degrees of productiveness, from the dry and arid rocks of the south-western frontier overrun with brushwood, to the hills of Chittagong and Tenasserim clothed with magnificent forests. Taken as a whole, however, the soil of Bengal, enriched as it is by the combined influence of fierce suns and deluging rains, may be said to be characterized by an amazing fertility. Its productions are those both of the tropical and the temperate climates. Of the grains which contribute to the subsistence of man, rice is of the first importance: it is the great staple of Bengal agriculture, is particularly luxuriant within the tract of inundation, and thrives in all the southern districts. It is sown after the first showers at the end of March down to the setting in of the rainy season, and occupies a period ranging (according to its variety, of which there are three principal deno-

Bengal. minations) from three to five months to ripen. The early crop is sown broadcast; the later crop, after the seed has attained the height of a few inches, is planted with the hand in rows at the distance of about a foot asunder. The rice-harvest is succeeded by the cold-weather crops, which are sown in autumn and reaped in spring. They consist chiefly of vetches, gram, barley, pease, mustard, &c. Millet and other small grains, sown at the beginning of the rains and reaped at the end, constitute the food of the poorer classes, and, bearing a very low price, are of importance. Maize is less cultivated in Bengal than in those countries where the climate is more suitable, having no preference above millet to compensate for the greater labour required for its culture. Potatoes have lately been introduced into Bengal, and have succeeded well. They are suited to the climate; and the small potato is little inferior to that raised in England. Esculent plants are found in Bengal in great abundance and variety. The different species of the cucumber are much more numerous than in Europe, and whole fields are covered with them. The water-melon is of incredible size; and its stalk, leaves, and blossoms form a finely variegated matting, with which most of the cottages in the villages are entirely covered.

The universal and vast consumption of vegetable oils which takes place in Bengal is supplied by the extensive cultivation of mustard, linseed, sesamum, and palma-christi, in addition to the produce obtained from the cocoa-nut. The sesamum comes to maturity during the rains, or soon after them, the others during the cold season. Among the most important of the commercial crops are tobacco, sugar, the opium poppy, indigo, cotton, and silk, most of which require land solely appropriated to their peculiar culture; of late years coffee has been successfully cultivated. Tobacco, which was unknown in India before the discovery of America, is now produced everywhere. The sugar-cane has flourished in Bengal from the remotest times; there is scarcely a district in which its cultivation is not pursued with success, and there seems to be no limit to its production, except the demand for it. It is cheaply and frugally manufactured; and as it now enters the British market on equal terms with West India sugar, it forms an important article of export. The manufacture of indigo appears to have been known and practised in Bengal from an early period; and from the East Europe was supplied with this dye until the superior produce of America engrossed the markets. European skill has, however, succeeded in reviving this branch of trade in Bengal, and the indigo now exported from this presidency amounts to five-sixths of the supply obtained from the whole world. Cotton is raised in abundance, but the produce scarcely exceeds the consumption: and the demand of the British and China markets for the cotton wool of India is almost wholly supplied from the western side of the country. Silk is an ancient product of India; the silkworm, it is said, being originally introduced from China. Formerly the raw material was brought from India to Greece and Italy, whence Europe was chiefly supplied. Bengal still carries on a trade in this valuable article; and although the quality is scarcely equal to the finest Italian silk, the annual export from Calcutta exceeds in value half a million sterling. A coarse species of silk is procured from the wild silkworm, which is found in the countries bordering on Bengal, and in several districts included within it. It is rendered useful in the fabrication of inferior silks, though bearing no comparison to the produce of the domesticated insect. The cultivation of the poppy is entirely regulated and controlled by the government. Annual contracts are made with the farmers to sow certain quantities of land with the plant, and to deliver the produce to the government in the form of opium at a fixed price. The sowings commence in November, and the crop arrives at maturity by the end of February. The revenue realized by the government from the sale of opium produced in Bengal alone amounts to between two and three millions sterling per annum. Bengal.

The orchard is a great object of cultivation with the peasant in Bengal; and it attaches him to his native soil, from the almost superstitious predilection which he feels for the trees planted by his ancestor. The seasons, however, from the long continuance of the rains, which occupy the greater part of the summer, are not particularly favourable for bringing fruit to maturity; yet the orange, lime, shaddock, citron, tamarind, and other fruits, may be reckoned among the productions of Bengal. Orchards of mango, a tree thriving with little care, and yielding a fruit esteemed one of the best among those of India, diversify the plains. In size and foliage this tree resembles the Spanish chesnut; its fruit is extremely delicious, and is said to surpass in flavour the large yellow peach of Venice. Another fruit-tree is the cocoa-nut, valuable not only on account of the nut, from which a superior oil is largely extracted, but in consideration also of its timber, which is peculiarly fitted for the construction of water-pipes and other useful purposes. Even the husk which envelopes the fruit furnishes a fibre from which the best cordage is manufactured. The mulberry is extensively planted in consideration of its leaves, which afford the food of the silkworm. Assam abounds with the genuine tea plant; and the bassia thrives in various localities, especially in the hilly districts. Its produce is esculent and nutritious, and its flowers yield an intoxicating spirit. From its seeds is expressed an oil which is sometimes used as a substitute for butter. There are also valuable forest trees, among which may be noticed the teak, equal to the oak for purposes of ship-building, the sal and the banyan. There is also the bamboo, which, being hollow, light, and strong, is serviceable in supplying the peasant with materials for his buildings, as well as for the manufacture of baskets, mats, and other articles of like character, to which, when split, its flexible fibre is well adapted.

Minerals. From the alluvial character of the greater portion of the soil of Bengal, no great amount of mineral wealth is to be expected. In the hilly tracts, however, both in the eastern and western parts of the country, two of the most useful products which the mineral kingdom can boast, coal and iron ore, exist in abundance. Gold, in the form of dust, is found in a few places, but not in quantities sufficient to encourage to any extent the search for it.

Landed tenures and land tax. The lands in Bengal, prior to the entrance of the British, were under the management and control of rajahs and zemindars, who collected the rents from the immediate occupiers and cultivators, and were held responsible for the payment of a fixed yearly sum into the treasury of the nabob. The titles of the different classes of occupiers were not very exactly defined; and in the anarchy which prevailed in the country, rights of every description were often violated. When the British obtained possession of Bengal, a difference of opinion arose respecting the character of the zemindars and the rights of the tenantry; one party asserting that the zemindar was the true landlord, in whom alone was vested the proprietary right; the other contending that the cultivators were the real proprietors, and that the zemindar was merely the collector of the revenue for the behoof of the sovereign, who, according to the Eastern maxims of policy, was the proprietor of all the lands in the country. Without entering into a controversy, which at this period can be attended with no practical results, it seems certain, and is indeed admitted on all hands, that the lands were assessed in a certain rate for the public tax; and that as long as this tax was regularly paid, the occupiers of land were secured in the possession of their properties, which they mortgaged for debts, and quietly transmitted to their heirs through a series of generations. It was not, however, to each individual occupier, but to the zemindar, that government looked for the immediate payment of the tax, which he again col-

Bengal. lected from the under-tenants, called the ryots or cultivators; and whether we admit the zemindars to be proprietors, or merely government stewards, it seems clear that the tax was a sort of quit-rent, and that its regular payment was the tenure by which both zemindar and cultivator held their properties. Between the acquisition of the Dewanny in 1765 and the year 1793, various expedients were resorted to by the British government in the collection of the land revenue; and during that period the relation between the zemindar and the cultivator remained undisturbed. In the year last mentioned, however, Lord Cornwallis introduced into the lower provinces the permanent settlement, whereby the state pledged itself not to increase the public demand on the land at any future period. The arrangement was made not with the cultivators, whose rights were virtually disregarded, but with the zemindars as the proprietors of the land; and there can be little doubt that the settlement was based upon erroneous principles. This is the more extraordinary, as in the discussions which took place previous to the settlement a sound and just view of the subject seems to have prevailed. It was admitted, that the cultivator had a right to the soil so long as he paid the public assessment, which was held to have been fixed beyond the power of the zemindar. It was acknowledged that the zemindar had no right of absolute property in the land itself, and there was no proof "of the existence of such right discernible in his relative situation under the Mogul government in its best form." Yet the Bengal government proceeded to recognise the zemindars as the actual proprietors of the land, and to transfer to their keeping, and surrender to their mercy, the rights of all other persons,—rights far more generally admitted and respected than the right of the zemindar to collect and pay over the revenue of government. The right of the ryot appears, as has been expressed, to be "the greatest right in the country," and "a right which never seems to die." The zemindars have in many cases been in a state of constant change, but the right of the ryot is believed to be inalienable. He may quit his land for any period of time, and the cultivation may be assumed by others; but if he or his heir return and reclaim the land, he has only to come to a compromise with the party in possession for the value of the crop on the ground, and his inheritance is restored to him immediately.

The permanent zemindary settlement was a favourite plan of Lord Cornwallis, and undoubtedly originated in benevolent intentions. Its effects, however, have not been such as its projectors anticipated. It was felt and declared to be "the duty of the ruling power to protect all classes of the people, and more particularly those who from their situations are most helpless;" but the interests of all parties, except of the zemindars, were unfortunately sacrificed.

By the permanent arrangement the amount of the payment to government, which had previously been variable, was fixed in perpetuity. But while the government thus excluded itself from any prospective increase of revenue, by limiting its own demand upon the zemindar, it did not protect the cultivator from oppression, by limiting the demand of the zemindar upon him. A provision was indeed made that puttahs or leases should be granted; but this was, in fact, annihilating the rights of the superior class of cultivators who had an hereditary title to their land, and reducing them to the condition of the inferior class who possessed no hereditary right of occupancy. The zemindar was elevated from the situation of a revenue agent to that of a landlord. He was enjoined to grant leases, but he might demand whatever terms he pleased, and obtain the best that he was able. He even acquired a power to dispose of rights far more ancient, and in the eyes of the people more venerable, than his own; and might, to use the words of the home government, "oust even the hereditary ryots from the possession of their lands, when the latter refused to accede to any terms of rent which might be demanded of them, however exorbitant." The local government had anticipated, that the reciprocal wants of the zemindars and cultivators would compel them to enter into just and equitable arrangements; but these flattering expectations were not realized, and it is almost impossible not to feel some surprise that they should have deceived the good and able men by whom they were indulged. The reciprocity, as Lord Hastings observed, is by no means clear. It indeed resembles some other projects of alleged reciprocal advantage, of which it has been said that the reciprocity is all on one side. The zemindar wants cultivators; but, in the language of Lord Hastings, "he wants them upon his own terms; and he knows that if he can get rid of the hereditary proprietors who claim a right to terms independent of what he may vouchsafe to give, he will obtain the means of substituting men of his own; and such is the redundancy of the cultivating class, that there will never be a difficulty of procuring ryots ready to engage on terms only just sufficient to secure bare maintenance to the engager." The existence of such a state of things justified his lordship in affirming that, "if it were the intention of our regulations to deprive every class but the large proprietors, who engaged with government, of any share in the profits of the land, that effect has been fully accomplished in Bengal." This was not indeed the intention of the originators of the permanent zemindary settlement, but it has unhappily been the result of their measures. Bengal.

Cotton piece goods form the staple manufacture of Bengal; though the use of Indian fabrics of this description in Europe has almost entirely ceased, while even in India the demand for them has been in a great degree superseded by the cheaper goods of Great Britain. The district of Dacca, in the eastern quarter of Bengal, has long been famed for the manufacture of plain muslins, distinguished by various names according to the fineness and the closeness of their texture, as well as for flowered, striped, or chequered muslins of the most beautiful and exquisite fabrics. Several kinds more closely woven are manufactured on the western side of the delta of the Ganges; but those of a more rigid texture do not seem to be limited to particular districts: coarse turbans and handkerchiefs are also made in almost every province. Under the general appellation of calicoes, are included various species of cloth, which are still distinguished by their Indian designations. Moorshedabad and its neighbourhood is the chief seat of the silk manufacture. Manufactures and commerce.

The internal trade of Bengal consists chiefly in the exportation from the grain districts of corn and rice in exchange for salt. The supply of this article in Bengal is provided partly by manufacture conducted on account of the government, partly by importation, and to a small extent by private manufacture under a system of excise. The duty on all imported salt is at the rate of five shillings on 82 lb., or about three farthings per lb.; and the same rate of duty is levied on the home manufacture of the article, the prime cost of which amounts to about one farthing per lb. The wholesale price of salt at Calcutta may therefore be estimated at one penny the pound. Its supply is no longer a monopoly; for though the manufacture and sale have not been relinquished by the government, yet the public participate in its provision, under a combined system of customs and excise. The net revenue derived from salt by the government within the presidency of Bengal exceeds a million and a half sterling per annum.

Salt is a very ancient source of revenue in the East; but a feeling against its manufacture being carried on by the government has been for some time on the increase. During the parliamentary session of 1853, a clause was proposed to be inserted in the India bill, then in its progress through parliament, forbidding the manufacture after the 1st May 1856; and though opposed by the ministry, it was in the House of Commons carried. By the House of Lords it was however rejected, it being deemed unsafe thus suddenly to

Bengal. diminish the resources of India by so large an amount as that of the revenue produced by the trade as at present conducted. The facilities afforded for the introduction of English salt have for several years past caused a great increase of the imported article, the quantity received in Calcutta in the official year 1850–51 being double that of previous years.

The internal trade of Bengal is greatly aided by the navigable communications which intersect the country in every direction. The boats used in this navigation vary in form and construction, being each adapted to the nature of the rivers which they generally traverse. Steam navigation has been introduced upon the Ganges with success; and the macadamized trunk road from Calcutta to Delhi has afforded facility of communication with the capital to various parts of the presidency: but there can be little doubt that in the course of a few years the rivers and roads of Bengal will alike become subsidiary to the great arteries of communication which, in the form of railways, are now commencing to intersect the country. The line from Calcutta to Burdwan is advancing rapidly to completion; from this point it will be continued in a northerly direction to Rajmahal on the Ganges, whence it will traverse the heart of the presidency in a north-westerly direction to Allahabad.

Bengal carries on an extensive commerce with Britain. The exports consist chiefly of all the staple articles of the country, such as cotton, silk, sugar, rum, and indigo. The imports are metals of all sorts, wrought and unwrought; woollen and cotton manufactures of various kinds, which can be sent from Britain and sold cheaper than the home manufactures of the same description; naval and military stores; gold and silver bullion; and almost every article of British manufacture. An extensive trade is carried on to China and the countries and islands to the east. The exports are chiefly opium, saltpetre, gunpowder, cotton, and cotton piece goods. Bengal.

The wild animals are such as are commonly found in Hindustan, namely, the elephant, the rhinoceros, the bear, the tiger, the leopard, the wild boar, the jackal, and the buffalo, with apes, monkeys, &c., which swarm in all the woods, and some times plunder the fruit shops of a village; for, being considered sacred animals, they are never disturbed by the natives. The elephant is tamed for domestic uses, and is found extremely valuable in the military service. The Ganges and its numerous tributary streams abound in a variety of excellent fish; and during the periodical rains, when reservoirs and jhils overflow, and the rivers rising run into every creek, fish are to be had for the mere catching, and then become the food of the poorest classes. It also abounds in a peculiar species of crocodile. Animals.

The area and population of the several districts and territorial divisions comprised within the presidency are given in the table below. Population.

District.	Area, Sq. miles.	Pop.	District.	Area, Sq. miles.	Pop.	District.	Area, Sq. miles.	Pop.
Jessore	3,512	381,744	Birbhoom	4,730	1,040,876	Cachar	4,000	60,000
Twenty-four Pergunnahs	1,186	288,000	Dacca	1,960	600,000	Lower Assam: Camroop	2,788	300,000
			Furreedpore and Deccan Jelalpore	2,052	855,000	Lower Assam: Nowgong	4,160	70,000
Burdwan	2,224	1,854,152				Lower Assam: Durrung	2,000	80,000
Hooghly	2,089	1,520,840	Mymensing	4,712	1,487,000

The following are the principal towns, with their population: Calcutta, 413,182; Dacca, 60,617; Moorshedabad, 146,963; Burdwan, 53,900.

Small villages containing from 100 to 500 inhabitants are very numerous; forming, in many parts of the country, a continuous town for many miles along the banks of the rivers, and presenting to the inland navigator, as he passes along, the cheerful bustle of a crowded population. The genuine Bengali towns are not arranged into streets, but into divisions of east, west, north, south, and centre. The Hindus, Mahometans, and others not professing either of those creeds, reside each in their own quarter. A Bengal hut has a pent roof constructed of two sloping sides, which meet in a ridge, forming the segment of a circle, so that they have the appearance of a boat turned upside down. The Bengali has one hut for himself and another for his cattle. The framework in general consists entirely of bamboos. The door is the only opening in the hut.

The elevated tracts in Bengal are inhabited by a race of a different origin from the people of the plains. In the northern mountains, beyond the limits of the province, the natives appear to be of a Tartar origin, by which race also the northern parts of Bengal are peopled. The high country which Bengal includes on the west is peopled by several races of mountaineers, who are supposed to be the aborigines of the country, being distinguished by religion, character, language, and manners, as well as by features, from the Hindu natives. Some of them have scarcely emerged from a state of barbarity. In the mixed population of Bengal the Hindus and Mahometans are easily seen to be distinct classes, as among the latter the Mogul, the Afghan, and their immediate descendants, may be distinguished from the naturalized Mussulman. The character of the Bengali has never been held in high esteem. That he is pusillanimous cannot be denied; that he is deficient in a regard for truth and honesty must be readily admitted; but at the same time it ought not

Benguela.

to be forgotten that the peasant of Bengal has been overridden for ages by an uninterrupted rule of priestcraft and oppression, of one or the other of which both his weaknesses and his vices are the genuine offspring. In the enumeration of his good qualities, patient endurance must certainly not be omitted. He is, moreover, acute and intelligent. Under the beneficent rule which is now paramount in India, the defects of character which have been generated by despotism may be expected to lose their universality; those which have had their rise in superstition will probably be of longer duration, and will not, perhaps, give way to the more robust qualities, either of disposition or intellect, until the influential classes who are now being educated in the government colleges shall diffuse European knowledge throughout the masses of the population. A list of the government colleges and schools, in which a complete education in European literature and science is afforded through the medium of the English language, is given below. The names of the Oriental institutions supported by the state are appended, together with the number of pupils attached to each institution, whether British or Oriental.

Of Bengal, prior to the Mahommedan invasion of India, our knowledge is very imperfect. From its conquest by Shahabudin at the commencement of the thirteenth century, it appears to have been ruled in feudal subordination to the empire, until the year 1340, when, during the reign of Mohammed Toghluk, it succeeded in throwing off its allegiance. A few years later, the successor of Toghluk consented to receive an embassy from Bengal, and thus recognised the independence of its ruler. In 1528 the king of Bengal, having been defeated by Baber, consented to terms of peace. Shortly after the province was again brought under the dominion of Delhi by the Afghan monarch Shir Shah; and though subsequently it succeeded in re-establishing its independence, it was finally reunited to Delhi by the Emperor Akbar, who formed it into a soubah or viceroyalty of the empire. Bengal continued to be ruled by governors under the Mogul dynasty, until the breaking up of the empire in the middle of the last century. The attack upon Calcutta by the nabob of Bengal in 1756, and the barbarous treatment of the servants of the East India Company, led to the battle of Plassy, and to the increased power and influence of the British. In 1765, the Emperor of Delhi conferred upon the East India Company the dewanny of Bengal, Bahar, and Orissa, and thus did this part of India form one of the earliest and most important of the acquisitions of the British in the East. (E. T.)

Bengal Bay || Benguela.

Bengal, Bay of, a portion of the Indian Ocean, of the figure of a triangle, having on its western side the coast of Bengal, and on the east the coast of Arracan, Pegu, and the Malayan peninsula. Its two sides, from Bengal to Ceylon on the west, and to Junkseylon on the east, may be estimated at 1120 miles in length, and the whole is comprehended within the latitudes of 8° and 20° N. At the bottom of the bay the breadth from Chittagong to Balasore is not above 250 miles; and at its mouth, from Cape Comorin to the Malayan peninsula, the breadth may be estimated at 1200 miles. The western and eastern coasts of the Bay of Bengal form a singular contrast in all the points most essential to a navigator. On the western coast there are no harbours for large ships, while on the eastern coast there are many excellent harbours, such as Arracan, Cheduba, Negrais, and Syriam, in Pegu; a harbour near Martaban, Tavay river, and King's Island; and several harbours in the Mergui Archipelago, besides Junkseylon, Telebone, and Pula Lada. Off the west coast of Coromandel there are no soundings about thirty miles from the shore, while the east coast has soundings two degrees from it. Coromandel presents an open country: it is often parched with drought from winds blowing over sultry sands; the mouths of its rivers are shallow from bars of sand, and it is often visited by dangerous gales. The east coast, on the other hand, is covered with wood. The climate is always temperate; the rivers are deep and muddy; and the weather is generally calm. The monsoons blow over the Bay of Bengal, though it is remarkable that here, as in many parts of India, strong winds are found blowing directly from the sea, while at some distance from the land it is a dead calm. Thus in Bengal there are strong northerly winds, while at sea calms prevail until May and June; and on the Malabar coast the south-west monsoon does not commence blowing till the beginning of the rainy season, while on shore there are strong westerly winds about and after the time of the vernal equinox. (D. B—N.)

BENGUELA, a considerable country on the western coast of Africa, included in the territory of Angola. Being occupied by the Portuguese, to the exclusion of all other European nations, the knowledge of it is withheld from the latter with the most jealous care. The general observations made upon the coast of Angola will in a great measure apply to Benguela. The air is said to be unwholesome, the water is bad, and the natives are extremely fierce and uncivilized. The mountains contain mines of copper, which is extracted only in very small quantities. The port of St Felipe de Benguela was formed by the Portuguese on the Bahia das Vallas or Cone's Bay, and made the centre of their trade upon this coast, especially of the iniquitous traffic in slaves, which is still clandestinely carried on. The articles almost exclusively in demand among the natives are coral and beads, which are not only used as ornaments, but circulate as

Benicarlo || Benin.

money. The few Portuguese ships which now pass to and from the East Indies touch here for refreshment. Long. 13. 37. E. Lat. 12. 30. S. Pop. of town about 3000.

BENICARLO, a city of Spain, in the province of Castellon de la Plana, on the coast of the Mediterranean. It is celebrated for its red wine, of which large quantities are annually exported to Bordeaux for mixing with clarets and other French wines. Pop. 6060.

BENIN, an extensive country of Western Africa, situated on a bay or bight of the same name, near the eastern extremity of the Gulf of Guinea. Here commences that long chain of estuaries by which the Niger discharges itself into the ocean. See NIGER.

Benin was discovered by the Portuguese about the year 1485. It escaped the observation of Diego Cam when he sailed from El Mina to the mouth of the Congo; but tidings of it having been there obtained, Alfonso de Aveiro sailed thither, and brought the first specimen of the plant called long or Guinea pepper. He came accompanied also by an ambassador from the king of Benin, requesting, it is said, that missionaries should be sent to instruct the people in the Christian religion. The king of Portugal accordingly despatched an expedition under Fernando Po, who discovered and gave his name to a fine island near the mouth of the gulf; and having ascended the river, established a settlement at Gatton. A church was built, and upwards of a thousand persons received baptism. Much interest was excited by the account of a regular embassy sent at the accession of every new prince to the court of a powerful sovereign named Ogané, whose capital lay about 700 miles to the eastward. He was held in almost religious veneration, and his sanction was considered necessary to render valid the title of any new monarch. This mysterious prince maintained himself in retired pomp, and at every audience a silk curtain concealed him from view. At the parting interview, however, his foot was put forth from behind the curtain, and was venerated as a sacred object. He delivered to the ambassador a staff, a helmet, and a cross, all of brass, to be presented to his sovereign. From these circumstances the Portuguese inferred that this was the Prester John or Christian prince whom they expected to find in the interior of Africa; but Major Rennell has more reasonably concluded that he was the king of Ghana or Cano, who then held extensive sway over that continent.

The Portuguese carried on for some time a brisk trade in slaves, who were carried to El Mina, and sold to the natives of the Gold Coast. John III., however, prohibited this nefarious traffic; and as the situation was found very unhealthy, while the conversions were professed only with the view of obtaining military aid against their neighbours, the settlement was ordered to be withdrawn. The Dutch afterwards established factories, and maintained them for a considerable time, chiefly with a view to the slave trade. The English and French have also formed occasional settlements. But all these are at present abandoned, and trading vessels come merely to the mouth of the river. On the whole, the river of Benin has always been, and now is, much less frequented for commercial purposes than that of Bonny and the towns situated at the opening of more southern estuaries.

The coast of Benin presents a succession of river branches, all diverging from one great trunk, connected and interlaced with numerous creeks and channels, which afford easy navigation for boats from one to the other. The whole of this territory consists of an immense swamp, either covered with water or composed of soft mud, out of which rises a dark and impenetrable forest. The waters are so muddy that no fish except eels can subsist in them. The river, called by the Portuguese Formosa, is about two miles wide at its mouth; but it is crossed by a bar of mud, on which there is only twelve feet of water at spring tides. Eighteen miles up is New Town, where vessels can anchor in 3½ fathoms water. It is a mere trading station, consisting of hovels built on a foundation of mud, so soft as to render it necessary to place old canoes with their bottoms upwards to form a passage from house to house.

Benish-Days.

At New Town a branch strikes off on each side, and these are followed by traders in preference to the main trunk. The left or northern branch leads first to Gatton, the port of Benin, to which barks of sixty tons can ascend, and near which dry land first appears emerging out of the morass. Benin, the capital, is forty miles further up the river.

From information obtained on the Gold Coast, M. Dupuis considered Benin as exceeding in importance even Ashantee and Dahomey; possessing an extensive and highly cultivated territory, and capable of sending 200,000 men into the field, 10,000 of whom were armed with muskets. But Captain Adams, who appears to be the last that actually penetrated to Benin, leads us to believe this description exaggerated. The city was indeed found to cover a great extent of ground; but the houses were so scattered that the population did not appear to exceed 15,000. The country around was also fruitful, but by no means highly cultivated. Sheep, goats, pigs, and poultry, were plentiful; but the vegetable food consisted almost entirely of yams. No information, however, is given respecting the districts in the interior. The king is absolute, being revered by his subjects as a species of divinity. It is a crime to believe that he either eats or sleeps; and all offences against him are punished with the utmost severity. At his death, or that of any of his great men, numerous human victims are devoted to attend them in the other world; and every year, at the mouth of the river, three or four are presented as votive offerings, to attract ships and commerce. Yet the practice of human sacrifice does not appear to exist on the same dreadful scale as in Ashantee and Dahomey.

The large channel that branches off to the right from New Town communicates with the Rio de Forcados, and then with another river whose branches inclose the beautiful island of Waree, which is about five miles in circumference, and seems almost like a spot fallen from the clouds in the midst of a desert. Being somewhat elevated above the surrounding swamps, it is dry, verdant, and cultivated. The soil consists of a tenacious red clay, fitted for the manufacture of earthen jars, which form an article of trade. The island contains two towns, the joint population of which is estimated at 5000. The government is monarchical, but mild; and the natives seem to enjoy a considerable degree of freedom and equality. The houses are neatly built of clay, and some of them are ornamented with wooden pillars. Waree carries on a communication with the sea by New Town, which is at present dependent upon it.

The main stream of the Formosa extends upwards in an east-north-easterly direction, but is not navigable for ships of fifty tons burden for more than fifty miles. Europeans have never ascended it, nor received accounts of any town situated on its banks.

Since the abolition of the slave trade, the chief commodities to be obtained in the river of Benin are palm oil and ivory, both at tolerably cheap rates. The imports consist of salt, silk and cotton stuffs, guns and gunpowder, coral, beads, iron, brass, brandy, tobacco, &c. (See Lander's *Travels;* Clapperton's *Second Exped.;* Smith's *Voyage to Guinea;* Adams's *Remarks on the West Coast of Africa.* (H. M.)

BENISH-DAYS, among the Egyptians, a term applied to three days of the week, which are days of less ceremony in religion than the other four, and are so called from the *benish*, a garment of common use, not of ceremony. At Cairo the benish-days are Monday, Wednesday, and Saturday, on which the citizens throw off all business and ceremony, and go to their little summer-houses in the country.

Benjamin || Bennet.

BENJAMIN (Sept. Βενιαμίν), youngest son of Jacob, by Rachel. In Gen. lvi. 21, *sq.*, the immediate descendants of Benjamin are given to the number of *ten*, whereas in Num. xxvi. 38–40, only seven are enumerated, and some even under different names. This difference probably arose from the circumstance that some of the direct descendants of Benjamin died either early or childless.

The tribe of Benjamin, though the least numerous of Israel, became nevertheless a considerable race. In the desert it counted 35,400 warriors, and at the entrance of Israel into Canaan even as many as 45,600. The portion allotted to this tribe was encompassed by the districts of Ephraim, Dan, and Judah, and contained thirty-six towns (with the villages appertaining to them), of which the principal were Jericho, Bethagla, Bethel, Gibeon, Ramah, and Jebus or Jerusalem.

In the time of the Judges, the tribe of Benjamin became involved in a civil war with the other eleven tribes. This war terminated in the almost utter extinction of the tribe; but it eventually revived, and in the time of David it numbered 59,434 able warriors; in that of Asa, 280,000; and in that of Jehoshaphat, 200,000.

This tribe had the honour of giving the first king to the Jews, Saul being a Benjamite. After the death of Saul, the Benjamites declared themselves for his son Ishbosheth; until, after the assassination of that prince, David became king of all Israel. David having expelled the Jebusites from Zion, and made it his own residence, the close alliance that previously existed between the tribes of Benjamin and Judah was cemented by the circumstance that, while Jerusalem belonged to the district of Benjamin, that of Judah was immediately contiguous to it. At the division of the kingdom after the death of Solomon, Benjamin espoused the cause of Judah, and they formed a kingdom by themselves. Indeed, the two tribes stood always in such a close connection as often to be included under the single term Judah.

BENJAMIN *of Tudela*, in Navarre, a celebrated Jewish rabbi of the twelfth century, whose *Itinerary* is a literary curiosity. He visited Constantinople, Egypt, Assyria, and Persia, penetrating to the frontiers of China. Though credulous, and not accurate in discriminating fable from history, his work contains some curious notices of the countries he visited. The Itinerary was translated from the Hebrew into Latin by Arias Montanus in 1575. It appeared in French in 1734, and again in 1830. An English translation was published in 1783, with notes by the Rev. Benjamin Gerrans, from the Hebrew and Latin edition of the Elzevirs of 1633.

BENNET, HENRY, Earl of Arlington, a distinguished statesman in the reign of Charles II., was born of an ancient family in Middlesex, in the year 1618. In the beginning of the civil war he was appointed under-secretary to George Lord Digby, secretary of state. He afterwards entered himself as a volunteer for the royal cause, and did the king good service, especially at Andover in Hampshire, where he was severely wounded. He was made secretary to the Duke of York, received the honour of knighthood from Charles II. at Bruges in 1658, and was sent as envoy to the court of Spain. Upon the return of the king to England, he was called home, made keeper of the privy purse, and principal secretary of state. In 1670 he was of the council distinguished by the title of the Cabal, and one of those who advised the shutting up of the exchequer. In 1672 he was made Earl of Arlington and Viscount Thetford, and soon after knight of the Garter. "Henry Bennet, Lord Arlington (Macaulay's Hist., vol. i. p. 212), then secretary of state, had, since he came to manhood, resided principally on the Continent, and had learned that cosmopolitan indifference to constitutions and religions which is often observable in persons whose life has been passed in vagrant diplomacy. If there was any form of government he liked, it was that of France. If there was any church for which he felt a preference, it was that of Rome. He had some talent for conversation, and some talent also for transacting the ordinary business of office. He had learned, during a life passed in travelling and negotiating, the art of accommodating his language and deportment to the society in which he found himself. His vivacity in the closet amused the king; his gravity in debates and conferences imposed on the public; and he had succeeded in attaching to himself, partly by services and partly by hopes, a considerable number of personal retainers." He died in 1685. His *Letters to Sir William Temple* were published after his death.

Bennet || Benson.

BENNET, *Dr Thomas*, an eminent divine, born at Salisbury on the 7th of May 1673, and educated at St John's College, Cambridge. In 1700 he was made rector of St James's in Colchester; afterwards became lecturer of St Olave's, Southwark, and morning-preacher at St Lawrence, Jewry; and at last was presented to the vicarage of St Giles's, Cripplegate. His writings were chiefly of a controversial character. He died Oct. 9. 1728.

BENOIT, RENÉ, a famous doctor of the Sorbonne, and curate of St Eustace at Paris, was born at Savernières, near Angers, in 1521. He was a secret favourer of the Protestant religion; and that his countrymen might be able to read the Bible in their own tongue, he published at Paris the French translation which had been made by the reformed ministers at Geneva. This translation was approved of by several doctors of the Sorbonne before it went to the press, and Charles IX. had granted a privilege for the printing of it; yet when it was published it was immediately condemned. He had previously been confessor to Mary queen of Scotland during her stay in France, and attended her when she returned to Scotland. Sometime before the death of Henry III., Benoit, or some of his friends with his assistance, published a book, entitled *Apologie Catholique;* in which it was shewn that the profession of the Protestant faith was not a sufficient reason to deprive Henry king of Navarre of his right of succeeding to the crown of France. When Henry IV. had resolved to embrace the Catholic religion, Benoit assisted at the assembly in which the king abjured the reformed religion. In 1597 Henry promoted him to the bishopric of Troyes in Champagne, but he could never obtain the pope's bulls to be installed. He enjoyed however the temporalities of that bishopric for eleven years, when he resigned it. He died in 1608.

BENSERADE, ISAAC DE, an ingenious French poet, born in 1622 at Lions-la-Forêt in Normandy. He made himself known at court by his verses and his wit, and had the good fortune to please the cardinals Richelieu and Mazarin. He wrote, 1. A Paraphrase upon Job; 2. Verses for Interludes; 3. Rondeaux upon Ovid; 4. Several Tragedies. A sonnet of his, which he sent to a young lady with his paraphrase on Job, having been placed in competition with the *Urania* of Voiture, a dispute on their relative merits long divided the whole court and the wits into two parties, who were respectively styled the *Jobelins* and the *Uranists*. Some years before his death, Benserade applied himself to works of piety, and translated almost all the Psalms. According to the Abbé Olivet, he latterly withdrew from court to his residence at Gentilly, where he died on the 19th October 1691, in the eighty-second year of his age.

BENSHEIM, a city of the province of Starkenburg, in the duchy of Hesse-Darmstadt; situated between Darmstadt and Mannheim, about fifteen miles from the former. Pop. 4500, mostly manufacturers, or cultivators of vineyards.

BENSON, GEORGE, a learned dissenting minister, born at Great Salkeld, in Cumberland, in 1699. His mental capacity was so precocious, that at eleven years of age he was able to read the Greek Testament. He afterwards

Bent Grass || Bentham.

studied at Dr Dixon's academy at Whitehaven, from which he removed to the university of Glasgow. In 1721 he was chosen pastor of a congregation of dissenters at Abingdon, in Berkshire; in 1729 he received a call from a society of dissenters in Southwark, with whom he continued eleven years; and in 1740 he was chosen by the congregation of Crutched Friars colleague to the learned Dr Lardner. In 1731 appeared his "Defence of the reasonableness of Prayer, with a Translation of a Discourse of Maximus Tyrius, containing some popular Objections against Prayer, and an Answer to these." Subsequently to this he published Paraphrases and Notes on the Epistle to Philemon, the two Epistles to the Thessalonians, the first and second to Timothy, and the Epistle to Titus; adding dissertations on several important subjects, particularly on inspiration. In 1735 he published his *History of the First Planting of Christianity*, in 2 vols. 4to, a work of great learning and ability. He also wrote the "Reasonableness of the Christian Religion," the "History of the Life of Jesus Christ," a Paraphrase and Notes on the seven Catholic Epistles, and several other works, which procured him great reputation. One of the universities in Scotland sent him a doctor's diploma; and several prelates of the Church of England, as Herring, Hoadly, Butler, Benson, and Conybeare, bestowed on him marks of favour and regard. Dr Benson died in 1763.

BENT GRASS, a species of *agrostis*. It has bent and wiry stems, and is exceedingly difficult to eradicate from the soil.

BENTHAM, JEREMY, was born in Red-Lion Street, Houndsditch, London, on the 15th of February 1748. He received his boyish education at Westminster school, and entered Queen's College, Oxford, in the summer of 1760, when he was little more than twelve years old. It was ever a consolation to him, when he had formed the great leading opinions of his life, that he had been exempted, by his tender age, from the subscription of the Thirty-nine Articles. He had a precocious capacity for acquiring knowledge; and paternal vanity subjected him to a degree of educational forcing, accompanied by occasional displays of the acquisitions of the accomplished youth, which would not, according to ordinary anticipations, have been favourable to the progress of so original and self-constituted a mind as his became. The father, a sagacious attorney, who had realized a considerable sum by practice, brought up his promising son to the bar, as a sphere in which the fortunes of the family might in such hands rise to great state and eminence. There was, however, little permanent geniality between them, for the son turned into a course entirely his own, and disappointed all the glittering hopes of the ambitious father. In his own work, the *Chrestomathia*, Bentham has given a sketch, quite unconsciously, of that paternal ambition which he did not realize. "Of the apothecary," he says, "the ambition is to see his child a physician of the highest eminence; of the attorney, to behold in his son a lord chancellor; of the parish clergyman, to behold in his an archbishop. The Lord Chancellor More makes his reverence and begs a blessing, as in the great hall of Westminster he passes by his father, then sitting in the Common Pleas; but the puisne judge, and not the lord high chancellor, is the great object of envy to a paternal breast."

That the son should turn out a philosopher and a law reformer, instead of realizing his father's practical anticipations, was perhaps the more mortifying, as the attorney, after the death of Jeremy's mother, married, in 1765, the widow of Dr John Abbot and the mother of Charles Abbot, afterwards speaker of the House of Commons and Lord Colchester. The step-brothers were matched against each other; and as young Abbot went straight onwards through a course of practical advancement, the erratic self-will of his own son, destined by the father's ambitious anticipations for the woolsack, became the more mortifying.

Bentham.

With the exception of some trifling youthful efforts, Bentham's earliest publication was his *Fragment on Government*, which appeared in 1776. As of many of his subsequent works, the title contained nothing to lead men to a notion of its object, which in this instance was a political criticism on the fundamental principles of Blackstone's popular commentary on the law of England. Bentham was peculiar in almost everything; and though he was not deficient in an egotism and vanity of his own kind, yet his first publication, so far from being that nervous ordeal which it generally proves to other authors, was a matter of trivial and fugitive thought to him, for he was occupied, when he printed it, in elaborating his great work on the *Principles of Morals and Legislation*. Before it was completed he had been brought into a social circle which offered to him wider views and more genial immediate elements than the dusty inns of court or the money-making cronies who dined with his father. Lord Lansdowne, with the instinctive appreciation of high eminence which has been remarkable in his family, sought out the author of the *Fragment on Government*, and received him as a guest at Bowood. Bentham evidently relished the life he led there; he had the first society of his day to converse with, and could retire to write on ethics and jurisprudence when he pleased. The one romance of his life, indeed, centred in Bowood. Among the young ladies whom he met there, one, who must have been little more than a child when he approached middle age, made so deep an impression on his heart, that, more than twenty years afterwards, and when he had entered his fifty-fourth year, he made her a formal offer of marriage. The lady's answer—a refusal—has been preserved in the memoir of Bentham by Dr Bowring (*Works*, x. 419.) The rejection was conceived in a tone honourable both to the head and heart of the writer; and since death has removed all who were connected with this little incident in the life of a great man, it need, perhaps, no longer be concealed, that Miss Caroline Fox, Lord Holland's sister, was the person on whom Bentham had bestowed his affections.

Almost all the other events of Bentham's life are embodied in the preparation and publication of his books. With the exception of a tour in Russia which he undertook in 1785, and a subsequent visit to France, he lived the life of a hermit, admitting some chosen friends or pupils only to his table and study in Queen Square, Westminster, and generally labouring, through all available hours unnecessary for rest and refreshment, at his varied works. He died on the 6th of June 1832.

It has not been deemed necessary to make this article a critical history of his works, since they are amply noticed under various heads of the *Encyclopædia*. There is especially a full critical history of the fundamental principles of his ethical philosophy in the Introductory Dissertation by Sir James Mackintosh (p. 393 *et seq.*) It is there mentioned, that Bentham's writings on jurisprudence do not come within the scope of the dissertation. These works, which he began with systematic inquiries into the principles of the science, were in his latter years a continuous elaborate application of these fundamental principles to the existing state of the law in Britain, or, in practical language, they were works on law reform. They have had a singular literary fate, of which the *Rationale of Judicial Evidence*—published in five octavo volumes in 1826—may be taken as a type. The object of this work was to show how much more rational it is for the tribunal which examines evidence to decide what is to be believed and what discredited, than for the legislature to separate credible from incredible evidence, and, permitting the tribunals to listen only to the former, exclude the latter class as tainted. His opinions, elaborately maintained, were in his day deemed so paradoxical that very few people would undergo the task of reading what he said. Through the exertions of these few readers,

Bentham || Bentinck.

however, opinion has now been so entirely revolutionized, that, by the abolition of disqualifications, the principles of the *Rationale of Evidence* have been established by statute, and have become so familiar, as the only true and sound principles, that the book in which they are set forth is deemed unreadable, as a string of truisms. The same history attaches to many of his practical suggestions; and it would occupy considerable space to describe those projects first suggested from his utilitarian hermitage, which are now in legal force. He advocated a uniform system of poor-laws under central inspection and superintendence, and an organization for the protection of the public health by sanitary purification. He pleaded for the adoption of local courts, for the cheap conveyance of letters, for a register of merchant seamen, for the protection of savings'-banks and friendly societies as the depositories of the savings of working people, and for many other projects with the realization of which we are now familiar. Bentham's works were chiefly known through the French abridged translation of Dumont, of which a collected edition was published at Brussels in 1829 in three large octavo volumes. A complete edition of his works in English was commenced in 1838, under the superintendence of his literary executor Dr Bowring, and completed in 1842, in eleven volumes, royal octavo. (J. H. B.)

BENTHAM, *Thomas*, bishop of Lichfield and Coventry, was born at Sherbourn, in Yorkshire, in 1513, and educated in Magdalen College, Oxford. On Edward VI.'s accession to the crown, he threw off the mask of popery, which, during the equivocal reign of Henry VIII., he had worn with reluctance. On the accession of Mary he was deprived of his fellowship, and retired to Basle in Switzerland, where for some time he expounded the Scriptures to the English exiles in that city, but returned before the death of the queen, and was appointed superintendent of a private congregation in London. In the second year of Elizabeth, Bentham was consecrated bishop of Lichfield and Coventry. He died in 1578. He had the character of a pious and zealous reformer, and was particularly celebrated for his knowledge of the Hebrew language.

BENTINCK, WILLIAM HENRY CAVENDISH, third Duke of Portland, was born in 1738. During the American war he joined the Opposition; and on the resignation of Lord North he was appointed lord-lieutenant of Ireland, but held that office little more than three months, being recalled when Lord Shelburne came into power. He held the situation of prime minister when the coalition came into power, and went out of office with them. In 1792 he was elected chancellor of the University of Oxford, and shortly afterwards joined Mr Pitt's party. He was home secretary from 1794 till 1801; and in 1807 he succeeded Lord Grenville as first lord of the treasury. He continued in this office till within a short time of his death, October 30. 1809.

The abilities of his Grace were certainly but moderate, and altogether inadequate for the authorship of *Junius's Letters*, of which, absurdly enough, some have endeavoured to prove him the writer; but his understanding was good, and his political integrity has never been questioned.

BENTINCK, *Lord William George Frederic Cavendish*, better known as Lord George Bentinck, second son of the fourth Duke of Portland, by Henrietta, sister to the Viscountess Canning, was born February 27. 1802. He was educated at Eton, and at Christ Church, Oxford; after which he entered the army, and served for several years in the Guards. On retiring from the army, he acted for some time as a private secretary to his uncle Mr Canning, then prime minister; in which capacity he gave proofs of high ability for the conduct of public business. In 1828 he succeeded his uncle Lord William Bentinck as member for Lynn-Regis, and continued to represent that constituency during the remaining twenty years of his life. Till within three years of his death, Lord George Bentinck was little known out of the sporting world. His early attempts at public speaking afforded no indication of the abilities which the subsequent course of political events served to develop so conspicuously. His failures in the House of Commons seem to have discouraged him from the attempt to acquire reputation as a politician. The natural energy of his character, however, found scope in another arena. As one of the leaders on "the turf," he was there distinguished by that integrity, judgment, and indomitable determination, which, when brought to bear upon matters of weightier importance, placed him, with a rapidity almost unexampled, in the foremost rank of British senators. On his first entrance into parliament he belonged to what may be called the moderate Whig party, and voted in favour of Catholic emancipation, as also for the Reform Bill, though he opposed some of its principal details. Soon after, however, he joined the ranks of the Opposition, with whom he sided up to the important era of 1846. When, in that year, Sir Robert Peel openly declared in favour of free trade, the advocates of the corn-laws, then without a leader, after several ineffectual attempts at organization, discovered that Lord George Bentinck was the only man around whom the several sections of the Opposition could be brought to rally. His sudden elevation to so prominent a position took the public mind by surprise; but he soon gave convincing evidence of powers so formidable, that the position of the Protectionist party at once assumed an imposing aspect. Towards Sir Robert Peel, in particular, his hostility was marked and uncompromising. Believing, as he himself expressed it, that that statesman and his political colleagues had "hounded to the death his illustrious relative" Mr Canning, he combined with his opposition as a political leader a degree of personal animosity that gave additional force to the poignancy of his invectives. On entering on his new position, he at once abandoned his favourite pursuits, disposed of his magnificent stud, forsook all connection with the turf, and devoted his whole time and energies to the laborious and trying duties of a parliamentary leader. Apart from the question of the corn-laws, his politics were strictly independent. In opposition to the rest of his party, he supported the bill for removing the Jewish disabilities, and was favourable to the scheme for the payment of the Roman Catholic clergy in Ireland by the landowners. Having held no high office under government, his qualifications as a statesman never found scope beyond the negative achievements of a leader of Opposition; but it may be safely affirmed that nothing but his untimely death could have debarred him from acquiring a distinguished position among the statesmen of Britain. This sudden and melancholy event, caused by the rupture of a vessel in the heart, took place on the 21st September 1848, while his lordship was proceeding on foot to visit a friend in the country. His biography has been written by his friend the Right Hon. B. Disraeli.

Bentinck.

BENTIVOGLIO, GIOVANNI, was born at Bologna in 1443, two years before the murder of his father Annibale, then the chief magistrate of the republic. In 1462 Giovanni contrived to make himself master of the state, which he continued to rule with a stern sway for nearly half a century; but his encouragement of the fine arts, and his decoration of the city by sumptuous edifices, gilded his usurpation. He was finally expelled by Pope Julius II., in 1506, and died in the state of Milan at the age of seventy.

BENTIVOGLIO, *Guido*, Cardinal, an eminent statesman and historian, was born at Ferrara in 1579. After studying at Padua, he went to reside at Rome, where he became universally esteemed. He was sent as nuncio into Flanders, and afterwards to France; and when he returned to Rome he was intrusted by Louis XIII. with the management of the French affairs at that court. He was the intimate friend of Pope Urban VIII., and on the death of Urban public opinion marked out Bentivoglio for his successor. But on

Bentley. entering the Conclave, the excessive heat of the weather threw him into a fever, of which he died on the 7th of September 1644. He has left several works, the most remarkable of which are, *A History of the Civil Wars of Flanders; An Account of Flanders;* Letters, and Memoirs.

BENTLEY, RICHARD, one of the greatest critics of modern times, was born at Oulton in the west riding of Yorkshire, on the 27th of January 1662. His ancestors belonged to the higher class of English yeomen. His father, Thomas Bentley, who was the possessor of a small estate at Woodlesford, married, as his second wife, Sarah, the daughter of Richard Willie, a stone-mason at Oulton; and their first child was the individual who afterwards rendered the family illustrious. For the first elements even of classical learning he is said to have been indebted to his mother, who is described as a woman of an excellent understanding. After having been a day-scholar at the neighbouring hamlet of Methley, he was sent to the grammar-school of Wakefield. On the 24th of May 1676, he was entered as a subsizar of St John's College, Cambridge. Having continued at college for upwards of two years, he became a scholar on the foundation of Dr Dowman; and at the expiration of the third year, he succeeded to one of the Yorkshire scholarships founded by Sir Marmaduke Constable. At the regular period he took the degree of A.B. From a fellowship of his college he was excluded by a provision in the statutes, which prohibited more than two fellows from being chosen from the same county. He was however appointed head master of the grammar-school of Spalding in Lincolnshire. On attaining the age of majority, he disposed of his interest in the Oulton property to his brother; and the money thus procured he devoted to the purchase of books. After an interval of about twelve months, he became domestic tutor to the son of Dr Stillingfleet, dean of St Paul's. In July 1683 he took the degree of A.M. Soon after the Revolution, Stillingfleet, now Bishop of Worcester, sent his son James to Oxford, where both he and his tutor became members of Wadham College.

He now projected editions of Greek grammarians and of Latin poets; he indeed pursued an arduous course of study, which gradually prepared him for any department of classical enterprise. The plan which he contemplated as the foundation of his fame was a complete collection of the fragments of the Greek poets. This plan he never executed; but of his competency for such a task he has left sufficient evidence in his collection of the fragments of Callimachus, afterwards communicated to Grævius. At the suggestion, as is supposed, of the very learned Bishop Lloyd, he undertook the stupendous task of publishing a complete edition of the Greek lexicographers: but the general design, which was too vast to be properly executed by one individual, appears to have been abandoned after a short interval; and it is much to be regretted that he did not at least publish an edition of Hesychius, an author in whom he professes to have made upwards of five thousand corrections. Of his familiarity with this lexicographer he exhibited a sufficient specimen in his earliest publication, his *Epistola ad. cl. v. Joannem Millium, S. T. P.* subjoined to Dr Hody's edition of the chronicle of Joannes Malela Antiochenus, which was printed at Oxford in the year 1691. By the publication of this little work, at the age of twenty-nine, he laid the foundation of a high reputation among men of learning.

His next appearance before the public was in the character of a divine. He had received deacon's orders from Compton, bishop of London, in the year 1690, and soon afterwards had been appointed one of the bishop of Worcester's chaplains. In 1692 the four trustees, one of whom was Evelyn, honoured him with the first nomination to Boyle's lectureship. The eight discourses which he preached in consequence of this appointment, embrace a confutation of atheism: they are in a great degree directed against the principles of Hobbes and Spinoza, which have too certain a tendency to atheism, although they are not professedly atheistical; and Bentley claims the merit of having been the first to display the discoveries of Newton in a popular form, and to explain their irresistible force in the proof of a Deity. His reputation was greatly augmented by the publication of his lectures; of which the sixth edition, including other three discourses, was printed at Cambridge in the year 1735. The lectures were translated into Latin by Jablonski, who was himself a writer of distinguished learning. Nor did the merit of the author remain without its reward: in 1692, soon after he had taken priest's orders, he obtained a prebend in the cathedral of Worcester; and in the course of the following year, he succeeded Henry de Justel as keeper of the king's library. In 1694 he was again appointed to preach the Boyle lectures, and he then selected as their subject the defence of Christianity against infidels; but this series of discourses his friends could not prevail upon him to publish, nor has it been ascertained that the manuscript is still preserved. In the following year, his patron the bishop of Worcester gave him the rectory of Hartlebury, to be held till his old pupil should arrive at the canonical age. The interest of the same worthy prelate had, about this period, procured him the nomination of chaplain in ordinary to the king. It must be recorded as an instance of scandalous ingratitude, that, when the bishop's grandson Benjamin Stillingfleet was left an orphan, and was sent in the humble capacity of a sizar to Trinity College, Bentley refused to give him a fellowship, and preferred several competitors of inferior attainments. At the beginning of the year 1696, he ceased to reside in the bishop's house in Park-street, Westminster, and took possession of the librarian's apartments in St James's Palace; and in the month of July he took the degree of D. D. at Cambridge.

Bentley.

Dr Bentley was now making a rapid approach to the full height of his literary fame; and his principal efforts were more the result of accidental excitements than of his own deliberate plans. In the year 1692 Sir William Temple, one of the most fashionable writers of the age, had published an *Essay upon the Ancient and Modern Learning*, in which he strenuously opposed the opinions of Fontenelle and Perrault, who had given a very decided preference to the moderns. But his own learning was inadequate to so serious an undertaking, and his commendation of the ancients is therefore of very doubtful value. Of his mode of estimating the merit of modern writers, it has been justly mentioned as a curious specimen, that the names of Shakspeare, Milton, Bacon, and Newton, have not found a place in his essay. In confirmation of his position, that the oldest books extant are still the best of their kind, he produces the Fables of Æsop and the Epistles of Phalaris, which he believed to be the most ancient pieces of prose written by profane authors. And in reference to the work which bears the name of the ancient tyrant, he is pleased to remark, "I think he must have little skill in painting, that cannot find out this to be an original." The attention thus directed to Phalaris seems to have suggested the expediency of a new edition; and the dean of Christ Church, Dr Aldrich, committed the task of editing his epistles to the Honourable Charles Boyle, brother to the earl of Orrery; a young gentleman of pleasing manners, and of a relish for learning creditable to his age and station. On his admission at Christ Church, he was placed under the tuition of Atterbury, who, if not a profound, was at least an elegant scholar. In his editorial labours he was aided by his private tutor John Freind,

Bentley. then one of the junior students, and afterwards a physician of no small celebrity. The editor of Phalaris wished to procure a collation of a manuscript belonging to the royal library; but, instead of making any direct application to the librarian, he had recourse to the agency of Thomas Bennet, a bookseller in St Paul's Churchyard, who appears to have executed his commission with no extraordinary degree of zeal or dispatch. In order to conceal his own negligence, he is supposed to have misrepresented the entire transaction to his employers at Oxford; and the preface to Mr Boyle's edition of Phalaris, published in the year 1695, contains a sarcastic reflection on Bentley for his want of civility. To the editor he immediately addressed a letter, explaining the real circumstances of the case; but instead of receiving an answer in the spirit of conciliation, he was given to understand that he might seek redress in any way he pleased. It is however dangerous to take a lion by the beard.

Dr Wotton, his friend and fellow-collegian, had recently engaged in the controversy respecting the comparative excellence of the ancients and moderns; and after he had sent to the press his *Reflections upon Ancient and Modern Learning*, Bentley happened to state, in the course of their conversation, and in reference to the extravagant commendation bestowed by Sir William Temple, "that the Epistles of Phalaris are spurious, and that we have nothing now extant of Æsop's own composition." This casual remark was converted into a promise that he would furnish a written statement of his opinion, to be added to the second edition of the Reflections. To the second edition, which appeared in 1697, was accordingly subjoined Dr Bentley's "Dissertation upon the Epistles of Phalaris, Themistocles, Socrates, Euripides, and others, and the Fables of Æsop." Of the spuriousness of all the productions thus enumerated, his demonstration is by every competent judge admitted to be very complete; but his most vigorous efforts are directed against the Epistles of Phalaris. After having produced the chronological proofs of their spurious origin, he considers the language, and next the matter, of the Epistles, and concludes with an argument drawn from what he calls their late appearance in the world. This work certainly betrays some symptoms of hasty composition; but the number of mistakes or oversights which his adversaries were capable of detecting was surprisingly small. The entire disputation is managed with great learning, and with sagacity not inferior to his learning. The contemptuous strain of Bentley's animadversion excited great indignation in the members of Christ Church; and an answer was speedily prepared by a confederacy, which, however deficient in critical learning, was by no means deficient in self-esteem. The leaders were Francis Atterbury and George Smalridge, both of whom were afterwards elevated to the episcopal bench: Robert Freind, afterwards head-master of Westminster school, his brother John Freind, and Anthony Alsop, all students of Christ Church, are generally understood to have lent their aid. The share of Atterbury is sufficiently ascertained from a passage in one of his letters to Boyle, in which he reminds him that, "in writing more than half the book, in reviewing a good part of the rest, and in transcribing the whole, half a year of his life had passed away."[1]

The motley production, bearing the title of "Dr Bentley's Dissertations on the Epistles of Phalaris and the Fables of Æsop, examined by the Honourable Charles Boyle, Esq." was published in the year 1698; and in the following year Bentley published "A Dissertation upon the Epistles of Phalaris, with an Answer to the Objections of the Honourable Charles Boyle, Esquire." They are both Bentley. in the octavo form; the former extending to about 300 pages, and the latter to 655. The wits of Christ Church were overwhelmed with an immense mass of learning, and that so well digested, and animated with so much spirit, that it would be difficult to mention many critical works worthy of being compared with Bentley's Dissertation. His learning was superior, immeasurably superior, to that of the Oxford combination; nor did they find him inferior in the use of their own weapons of wit and sarcasm. Bentley's wit is not without a certain tinge of rusticity, but it is nevertheless full of poignancy. He everywhere maintains an air of undaunted confidence, and he doubtless felt for his adversaries that contempt which he so strongly expressed. As he has incidentally discussed many different topics of classical erudition, his work is interesting and valuable even to those who may not deem the principal question of much importance. The extent of his learning, and the dexterity with which he applies it to every subject that presents itself, are not more conspicuous than the intuitive sagacity of his conjectural emendations.

This controversy produced an ample number of tracts, which are chiefly anonymous, and have little intrinsic merit. On the side of Bentley's nominal antagonist, prejudice, as well as fashion, was strongly arrayed. It is not a little curious to read the following couplet in Garth's Dispensary, and to compare the partial estimate of contemporaries with the mature decision of posterity.

> So diamonds take a lustre from their foil
> And to a Bentley 'tis we owe a Boyle.

But it is only by himself that an author can be written down. A confederacy of wit and fashion may for a certain time succeed in exalting one writer above, and in depressing another below, his proper standard; but as no large community of men is without a latent sense of justice, no attempt of this nature can be attended with ultimate success; nor is it more certain that heavy or light bodies will sink or float according to their specific gravity, than that the reputation of good and bad writers will finally maintain some perceptible relation to their actual desert.

When Bentley produced this singular work, he was in the thirty-eighth year of his age. His literary merit, though not duly appreciated by the public, was well known to the most competent judges; and on the promotion of Dr Montague to the deanery of Durham, he was recommended to the vacant office of master of Trinity College, Cambridge. To this office he was admitted on the first of February 1700, and was thus placed in a situation of dignity and emolument; but his appointment was unpopular from the beginning, and his administration was marked by a series of the most flagrant acts of rapacity, injustice, and oppression. On the 4th of January 1701, he married Joanna the daughter of Sir John Bernard, Bart. of Brampton in the county of Huntingdon. In the course of the same year, Bishop Patrick bestowed upon him the archdeaconry of Ely, which, being endowed with the two livings of Haddenham and Wilburton, was an office of emolument as well as dignity. The residue of his ecclesiastical history we shall compress within the compass of a few sentences. His stall at Worcester he had resigned in 1700. In 1709 he was an unsuccessful candidate for the bishopric of Chichester. In 1717 he was elected regius professor of divinity. In 1724 he refused the bishopric of Bristol, and in 1730 the deanery of Lin-

[1] Atterbury's *Epistolary Correspondence*, vol. ii. p. 21.

Bentley. coln. If he had not disgraced himself by the indecent violence of his conduct, he would in all probability have attained to one of the highest stations in the church; but the history of his proceedings at Cambridge presents a sickening detail, which is happily unparalleled in the academical annals of the united kingdom. His great prosperity, operating upon the native arrogance of his disposition, and unattended by the salutary restraint of religious feeling, seems to have produced a total disregard of every consideration except those of his own power and interest. His government of Trinity College was that of an unprincipled despot. In the course of three years, he had no fewer than six lawsuits before the court of king's bench; and these animosities and contentions, injurious to the university, and scandalous to the church, commenced in the vigour of his manhood, and were only terminated with his long life.

Some of the fellows of the college made repeated and strenuous attempts to procure his removal from the office of master. Their first petition, dated in February 1709–10, was addressed to Dr Moore, bishop of Ely, as visitor of Trinity College; and among the thirty fellows who subscribed it was the celebrated Conyers Middleton, who afterwards proved the most formidable of his literary antagonists. After many proceedings of a preliminary nature, the cause at length obtained a hearing at Ely House in the year 1714, and was before the court for the period of six weeks. The visitor came to the conclusion that the charges of wasting the goods and violating the statutes of the college had been sufficiently established; and he accordingly directed a sentence of ejectment from the mastership to be prepared in due form; but having caught cold in consequence of his long sittings in the hall, he was seized with an illness which terminated fatally before judgment could be pronounced. To his successor in the see of Ely, Dr Fleetwood, fresh articles of accusation were speedily presented by one of the fellows, Edmond Miller, serjeant at law, subscribed by him "in the name and behalf of many of the fellows;" but the bishop declined to take cognizance of the cause, and a petition, subscribed by nineteen fellows, was in 1716 presented to the king. This attempt likewise proved ineffectual; and Dr Greene having succeeded to the bishopric of Ely, a petition was presented to him in the year 1729. The promoter in this suit was Robert Johnson, B. D., one of the fellows; and the articles of accusation, which are sixty-four in number, embrace almost all the material events in the history of the college for the space of eighteen years.[1] The final decision of the visitor was preceded by much litigation in the king's bench and house of lords; but at length, on the 27th of April 1734, he pronounced sentence of deprivation against the master, for dilapidating the goods and violating the statutes of the college. Bentley's usual intrepidity and address did not forsake him on so critical an occasion; and he placed his chief reliance on the very defective provision of the fortieth statute, according to which a master, convicted before the visitor of any of the greater offences there specified, is immediately to be deprived by the vice-master of the college. Soon after the sentence had been pronounced, his devoted adherent Dr Walker was appointed to this office. Notwithstanding various applications to the court of king's bench, the sentence was never carried into execution; and Bishop Greene dying in the year 1738, the course of nature, and not of law, put a period to the contest. In this protracted and complicated suit the master's share of the expenses amounted to no less than four thousand pounds; and this sum he had no scruple in drawing from the funds of the college. Bentley.

In addition to these disgraceful contentions with his own college, he engaged in a violent contention with the university. During the royal visit of 1717, several doctors of divinity were created by mandate; and on the performance of the ceremony by Dr Bentley as regius professor, he made an unauthorized demand of four guineas from each candidate. One of these was Dr Middleton, who paid the fee, and afterwards brought an action for its recovery in the vice-chancellor's court. The professor was convicted of contempt, and was deprived of all his degrees, which were only restored in consequence of a mandamus from the king's bench.

Soon after the first petition against him had been presented to the bishop of Ely, he had sufficient energy of mind to compose one of his most remarkable works, his *Emendationes in Menandri et Philemonis Reliquias*, in which Le Clerc is treated with the most caustic severity. Under the borrowed name of Phileleutherus Lipsiensis, they were committed to the press by Burman,[2] who was a willing agent on such an occasion. His next literary enterprise was his famous edition of Horace, which was printed at Cambridge, and was completed in the year 1711. In 1713, Anthony Collins published his *Discourse of Free-thinking;* and his work was followed by several answers, but the most effective of these was Dr Bentley's "Remarks upon a late Discourse of Free-thinking, in a Letter to F. H. D. D., by Phileleutherus Lipsiensis." The friend thus designated in the title-page was Francis Hare, D. D., who was then dean of Worcester, and was afterwards successively bishop of St Asaph and Chichester. Collins's superficial learning was exposed with unrelenting severity, and his arrogance was repelled by the most arrogant of mankind. Even the most pious may sometimes do well to be angry; but when a religion, breathing peace and gentleness, is defended in the worst spirit of its enemies, the cause of truth is but imperfectly promoted. Bentley's remarks were however written with much ability, and were received with much applause; nor did he leave his adversary the same power of imposing on the ignorant and unwary. In 1720 he issued proposals for publishing a critical edition of the Greek Testament, which were attacked by Dr Middleton with much ability, and perhaps with virulence not inferior to his ability. There is little or no reason to believe that his scheme was defeated by this angry exposure: he long afterwards reverted to the plan of such an edition; nor were his nerves so infirm, or his mind so unaccustomed to the utmost bitterness of invective, as to render it probable that he could be deterred by any literary opposition, however formidable. His edition of Terence and of Phædrus was published at Cambridge in 1726. At the suggestion of Queen Caroline, he afterwards undertook to prepare an edition of Milton's Paradise Lost;[3] a task for which he was neither qualified by the elegance of his taste nor by the course of his previous studies; and, of all his literary enterprises, this was the most injudicious and most unsuccessful. It greatly contributed to impair his general reputation as a critic; for many readers, unprepared to judge of his violent distortions in the text of Horace, were sufficiently prepared to judge of his violent distortions in the text of Milton; and certainly those who were left to form an opinion of his literary merits from the mere inspection of his lucubrations on the English poet,

[1] See Bishop Monk's *Life of Richard Bentley, D. D.* Lond. 1830, 4to.

[2] *Trajecti ad Rhenum*, 1710, 8vo.

[3] Lond. 1732, 4to.

could not but be astonished at his former renown. He resorts to the extraordinary device of introducing an imaginary editor, whom he chooses to represent as having not merely committed many unintentional errors, but even as having made various additions according to his own judgment or caprice. Another labour of his declining years was a projected edition of Homer; and it is deeply to be regretted that he did not relinquish more unprofitable pursuits, and devote himself to an undertaking so worthy of his name and reputation; but his literary projects were numerous, and his thoughts must often have been distracted by the perpetual succession of his quarrels and contentions. One object to which he directed much of his attention was the poet's versification, of which he proposed to effect a general restoration, derived from ancient manuscripts, the examination of the numerous quotations dispersed in ancient writers, and, beyond all other sources, the systematic insertion of the Æolic digamma. His edition of Manilius, which he had prepared about forty-five years before, was published in 1739, under the superintendence of his nephew, Richard Bentley, D.D.

The death of Bishop Greene, in 1738, had relieved him from the hazard of deposition; and he continued to enjoy his offices till 1742, when he died on the 14th of July, after having completed the eightieth year of his age. His wife had died two years before. His only surviving son, who bore the same name, was educated to no profession; it was one of the many scandalous acts of the father's administration, that the son was elected a fellow of Trinity College at the age of fifteen. The younger Bentley, who was considered as a man of excellent talents, was the author of several works, but is best remembered as the friend of Gray. When his father once found him reading a novel, "Why," said he, "read a book which you cannot quote?" The doctor's two daughters, Elizabeth and Joanna, were both married: the latter was the wife of Denison Cumberland, who was grandson to the learned bishop of Peterborough, and who himself became bishop of Kilmore, and the father of Richard Cumberland, one of the most eminent of the recent English dramatists.

The principal works published during the author's lifetime have already been enumerated; but we must not neglect to mention the posthumous collection entitled "Richardi Bentleii et doctorum Virorum Epistolæ partim mutuæ. Accedit Richardi Dawesii ad Joannem Taylorum Epistola singularis." Lond. 1807, 4to. Of this splendid volume two hundred copies were printed at the expense of the late Dr Burney, not with any view to publication, but as presents from the munificent editor. An enlarged edition of the same collection has very recently been printed in a more accessible form: "Richardi Bentleii et doctorum Virorum Epistolæ partim mutuæ: ex editione Londinensi Caroli Burneii repetiit, novisque additamentis, et Godofredi Hermanni Dissertatione de Bentleio ejusque Ed. Terentii, auxit Frid. Traug. Friedemann." Lipsiæ, 1825, 8vo. The Rev. J. Wordsworth has published an edition of Bentley's Letters, with notes, in 2 vols. 8vo; and a complete edition of his works by the Rev. A. Dyce, has appeared in 3 vols. 8vo. (D. I.)

BENZOIC ACID, BENZAMIDE, BENZINE, BENZYLE. See CHEMISTRY.

BENZOIN, or BENJAMIN, a concrete resinous juice which exudes from incisions made in the *Styrax Benzoin*, a tree of Sumatra, &c. It is a combination of resin and benzoic acid, and is much used by the perfumer on account of its fragrance.

BERAR. See NAGPORE.

BERBERIS, a genus of plants belonging to the nat. ord. of Berberidia, of which the best known is *B. vulgaris*, common barberry. The fruit of *B. aristata* and *B. Nepalensis* is prepared in India like raisins.

BERBICE. The colony of Berbice is described in the article GUIANA, BRITISH.

BERBICE, a river in British Guiana. Lat. at its mouth, 6. 20. N. Long. 57. 11 W. It runs from south to north, and discharges itself into the Atlantic Ocean. The coast on each side of it forms a bay at its entrance, which is nearly a mile in width, having a small island in the middle, called Crab Island, from the number of land-crabs on it. Outside the entrance of the river there is a bar of sand, over which at high tide there is seldom more than eighteen feet of water; but within, the water is of sufficient depth, and the river is navigable for ships of burden 200 miles from its mouth. On account of the bar, however, few vessels anchor here, preferring the port of Demerara.

BERCHEM, or BERGHEM, NICHOLAS, an eminent painter, born at Haerlem in 1624. He received instruction from several distinguished masters; and it was no small addition to their fame that Berchem was their pupil. The pictures of cattle and figures by this master are highly esteemed; and many of them have been finely engraved by John Visscher, an eminent artist in his own line. The distinguishing characters of Berchem's pictures are, the breadth and just distribution of the lights, the grandeur of his masses of shadow, the nature and simplicity in the attitudes of his figures, the just gradation of distances, brilliancy and transparency of colouring, the correctness and true perspective of his design, and the elegance of his composition. He died in 1683.

BERCHETT, PETER, an eminent historical painter, was born in France in 1659, and at the age of eighteen was employed in the royal palaces. He came to England in 1681, to work under Rambour, a French painter of architecture; but after staying a year, he returned to Marli. He revisited this country, however, and was employed by King William to decorate the palace then building at Loo, which occupied him fifteen months. Coming to England a third time, he painted the ceiling of the chapel of Trinity College, Oxford, the staircase at the Duke of Schomberg's in Pall-mall, the summer-house at Ranelagh, and various other works. Towards the close of his life he retired to Marybone, and painted only small pieces of fabulous history. He died there in January 1720.

BERCHTESGADEN, or BERCHTOLSGADEN, a small town, most beautifully situated on the south-eastern confines of Bavaria, and long celebrated for its extensive mines of rock-salt. Fresh water is brought into the mine, which, after acting a certain time upon the salt rock, becomes brine, and in that state is run off in pipes to a reservoir in the vicinity; whence by the aid of two celebrated water column engines, constructed by Reichenbach of Munich, it is raised 1500 feet, and conducted to Traunstein and Rosenheim, about forty miles farther inland. The town contains three old churches, and some good houses. Its inhabitants, amounting to about 1600, are principally employed in the mines and the manufacture of salt. Some few also are engaged in making toys and small articles of stag and chamois horns. Its vicinity comprehends the most picturesque portion of Bavaria; the snow-capped peaks of the Watzman towering over it to the height of 7000 feet, while the Königssee at its foot, one of the wildest lakes among the Alps, is not exceeded by any in beauty and sublimity. The small red trout of the Königssee, called by the common people *schwartzreitic*, are highly prized; and no portion of the Alpine range is better supplied with game, particularly the stag, the chamois, and the steinbok or ibex, an animal elsewhere almost extinct.

BERDASH, a name formerly used in England for a certain kind of neck-dress. The maker or vender of such articles was called a *berdasher*, whence our word *haberdasher*.

BERECYNTHIA, a surname of Cybele, derived from Mount Berecynthus, where she was worshipped.

BERENGARIANISM, a name applied by ancient ecclesiastical writers to the doctrine of those who deny the actual presence of the body and blood of Christ in the eucharist

Berengario || Berenice.

The denomination took its rise from Berengarius, archdeacon of the church of St Mary at Angers, who in the year 1045 publicly maintained the opinion of John Scotus that the bread and wine, even after consecration, do not become the true body and blood of our Lord, but only a figure and sign thereof; which is the distinctive feature of the Protestant doctrine. Berengarius died in 1088.

BERENGARIO, Giacomo, a celebrated anatomist and physician, born at Carpi, near Modena. He was a professor in the university of Bologna from the year 1502 until 1527, and may be considered as one of the chief restorers of anatomy, which he found in a very low state. He made several important discoveries in anatomy, and communicated the result of his researches in his various works. He employed mercurial frictions largely in his practice; but he was not the first who employed mercury, as is often erroneously reported.

BERENICE, daughter of Ptolemy Auletes king of Egypt, and eldest sister of the famous Cleopatra, ascended the throne on the deposition of her father by the Alexandrians, B.C. 58. Berenice, in order to support her authority, married Seleucus the brother of Antiochus XIII. king of Syria; but soon growing weary of her choice, she caused Seleucus to be put to death. She then married Archelaus, whom Pompey had made king of Comana in Pontus; but a few months afterwards Ptolemy was reinstated by the Romans, and Berenice and Archelaus were slain, B.C. 55. (Liv. *Epit.* 109; Dion Cass. xxxix. 55–58.)

Berenice, wife of Ptolemy Euergetes king of Egypt, cut off her hair in pursuance of a vow, and consecrated it in the temple of Venus. This deposit having disappeared, Conon the mathematician, in compliment to the queen, declared that her locks had been conveyed to heaven, and composed the constellation which to this day is called *Coma Berenices*. Callimachus celebrated the hair of Berenice in a poem, of which only a few lines are extant: it still exists however in the translation of Catullus.

Berenice, daughter of Costobarus, and of Salome the sister of Herod the Great, was first married to Aristobulus, son of the same Herod and of Mariamne. The cruel Herod having put his son to death, Berenice married a second time; and again became a widow, but whether or not by similar means it is not said. She accompanied her mother to Rome, where she enjoyed the favour of Augustus, and the friendship of Antonia the wife of Drusus, which ultimately proved of great service to her son Agrippa.

Berenice, or *Beronice*, grand-daughter of the preceding, and daughter of Agrippa I. king of Judæa, acquired a discreditable celebrity by her amours. She was betrothed to one Marcus, but he died before the marriage was consummated. Soon after she married her uncle Herod, who, at the desire of Agrippa, his brother and father-in-law, was created king of Chalcis by the Emperor Claudius. On the death of her husband, A.D. 48, she lived for a considerable time with her brother Agrippa, with whom it was rumoured that she committed incest. To avoid this scandal, she offered herself in marriage to Polemon, king of Cilicia, provided he would change his religion. He accepted her offer, was circumcised, and married her. But Berenice soon left him, and returned to Agrippa, with whom she was still living when St Paul appeared before him at Cæsarea, A.D. 62. She seconded her brother in his attempt to prevent the desolation of Judæa, and at the risk of her own life interceded with Florus to spare her miserable countrymen. This artful woman drew Titus into her snares; but the murmurs of the Roman people opposed an obstacle to their contemplated marriage, and she became the concubine of the emperor.

Berenice, the name of several cities, particularly of a celebrated seaport in the Sinus Arabicus, near Ras-Benas. Lat. 23. 50. N. Long. 35, 34. E.

Beresina || Bergamo.

BERESINA, or Berezina, a river of Russia, rising in the north of the province of Minsk, and falling into the Dnieper, after a course of 200 miles. It is connected with the Dwina by a canal, which thus establishes a communication between the Black Sea and the Baltic. The passage of the Beresina is celebrated as one of the most disastrous events in the retreat of Napoleon from Moscow. See France.

BEREWICHA, or Berewica, in our old writers, denotes a village or hamlet belonging to a town or manor. The word frequently occurs in Doomsday-book: e.g. *Istæ sunt berewichæ ejusdem manerii.*

BEREZOV, a Russian town of Siberia, on the river Soswa, 18 miles from its confluence with the Obi. It contains three churches and a chapel. Its northern situation forbids all kind of agricultural industry: the inhabitants subsist by hunting and fishing; and the furs which they procure are exchanged with the Russian merchants for such articles as they require. They also supply Tobolsk and other places on the Irtisch with dried fish in summer, and with frozen fish during winter. The inhabitants are chiefly Cossacks, and are much addicted to drinking. This town has afforded a place of exile to several distinguished statesmen. Berezov is 400 miles N.N.W. of Tobolsk. Lat. 63. 30. N. Long. 65. 55. E.

BEREZOVSKOI, a town and fortress of Asiatic Russia, in the government of Orenburg, on the river Oural. In the vicinity are several productive gold mines.

BERG, formerly a duchy of Germany, on the right bank of the Rhine, and bounded on the north by the duchy of Cleves, on the east by the county of Mark and the duchy of Westphalia, and on the south by the Westerwald. It contained about 1188 square miles. It was formerly subject to the elector palatine, but since 1815 has been included in the grand duchy of the Lower Rhine. The duchy of Berg was taken from Bavaria in 1806, and bestowed upon Murat, afterwards king of Naples, who derived from it the title of Grand Duke of Berg. It is a populous and flourishing district, very fruitful along the Rhine, but mountainous and woody towards the county of Mark. The principal rivers, besides the Rhine, are the Wipper, Agger, and Sieg.

BERGA (ancient *Bergium*), a town of Spain, province of Barcelona, in a mountainous district, 14 leagues N.N.W. of the city of Barcelona. It has a garrison, several churches and convents, and a hospital founded A.D. 1290. Pop. 6999, principally engaged in cotton weaving. It is a place of considerable industry and commerce.

BERGAMO, a province, or, as it is usually termed, a delegation, of the Austrian kingdom of Lombardy. It is bounded on the north by the delegation of Valtelino, on the east by those of Tyrol and Brescia, on the south by Cremona, Lodi, and Crema, and on the west by Milan and Como. The extent is about 1615 square miles, or 1,033,600 acres. It is divided into 18 districts, and these into 372 communes or parishes, and comprehends one city, 22 market-towns, and 333 villages. Pop. (1851) 378,123.

The whole northern part of the delegation is filled with the Alpine mountains, whose spurs extend to the capital; but the southern division forms part of the plain of Lombardy. The country is deficient in corn; but the surplus of cattle, with iron from the mines in the northern part, and the silk produced in the southern, are exchanged for the grain required by the inhabitants. There are manufactures of silk, and of woollen goods. There are some quarries of marble, and of other kinds of stone from which grindstones and whetstones are cut and prepared for export ation.

The capital of the province is the city of the same name, laid out on several elevations in the form of an amphitheatre, surrounded with walls and ditches, and defended by two insignificant forts. It is the see of a bishop, and the seat of the provincial courts of law; and comprehends, besides the

Bergamo ‖ Bergen-op-Zoom.

cathedral, fourteen churches, four hospitals, six orphan-houses, a number of monasteries and nunneries, town-hall, college, athenæum, public library, &c. Its principal manufactures are silk, woollen, cotton, and linen goods, hardware, &c. The largest fair in northern Italy is annually held here in the month of August, and continues for a fortnight. Pop. 32,000. Bernardo Tasso, the father of the illustrious Torquato was born here in 1493.

Bergamo (the ancient *Pergamus*), a city of Anatolia, on the river Mendere-Chai (ancient *Simois*), in Lat. 39. 4. N. Long. 27. 12. E. It is still a place of some importance, with a mixed population, estimated at 14,000. The houses are mostly small and mean, but it still preserves many remains of its former magnificence. See Pergamus.

BERGAMOT, a species of citron, *Citrus limetta*, distinguished from the orange and lemon by having wingless leaf-stalks. It is a native of the south of Europe, and is produced abundantly in the neighbourhood of Nice. The fruit has a delicious taste and smell, and its essential oil is highly esteemed as a perfume. The essence of bergamot is also called *essenzia di cedro*. It is extracted from the yellow rind of the fruit by cutting it in small pieces, and expressing the oil, or by distilling it from water. One hundred bergamots of Nice yield, by expression, 2½ ounces of oil.

Bergamot is also the denomination of a coarse tapestry, manufactured with flocks of silk, wool, cotton, hemp, cow's or goat's hair, and supposed to have been invented at Bergamo in Italy.

BERGEN, a fortified city and seaport of Norway, capital of the province of South Bergen. It is situated at the head of a deep bay, on the Atlantic, has a fine harbour with two good entrances, and is surrounded by hills, some of which attain the height of 2000 feet. The appearance of the town is picturesque; it rises in the form of an amphitheatre, and is generally well built, though some of the houses are of wood. Pop. (1845) 25,611, employed chiefly in the fishery. The export trade, which consists of stock-fish, lobsters, timber, rock-moss, skins, horns, fish-roes, herrings, oil, &c., is chiefly carried on with the northern countries of Europe. In 1842 the number of ships that entered the port was 1078, with a tonnage of 80,545.

Bergen contains a cathedral, several churches and hospitals, a national museum, diocesan college, naval academy, several public libraries, various charitable institutions, and a theatre. It is the seat of a tribunal of secondary jurisdiction, and of one of the three public treasuries of Norway. This city was founded in the eleventh century by one of the kings of Norway, and joined at an early period the Hanseatic League. Long. 5. 20. 33. E. Lat. 60. 24. N.

Bergen, a town of Prussian Pomerania, circle of Stralsund, and capital of the Isle of Rügen. It contains a castle, a court of justice, and a convent for noble ladies; and has some woollen manufactures. Pop. 3024.

BERGEN-OP-ZOOM, a maritime town of Holland, province of North Brabant, situated on the river Zoom, near its confluence with the Scheldt. The houses are well built, the market-places and squares handsome and spacious. It contains a town-house, grammar-school, a school of design and architecture, and has numerous earthenware manufactures, besides a considerable trade in anchovies. Pop. (1846) 8000. It is so strongly fortified, both by nature and art, as to be deemed almost impregnable. The fortifications are reckoned the masterpiece of the celebrated Cœhorn, the rival and contemporary of Vauban. In 1586 it was unsuccessfully besieged by the famous Duke of Parma; and afterwards, in 1622, it defied the utmost attempts of Spinola, who was forced to abandon the enterprize, after a siege of ten weeks, with the loss of 12,000 men. In 1747, however, it was taken by stratagem by the French under Count Lowendahl, and in 1814 was again rendered famous by an unsuccessful attempt of the British troops under Lord Lynedoch, then Sir Thomas Graham, to take it by a *coup de main* on the night of the 8th of March. The troops destined for this attack amounted to 3950, and were divided into four columns, two of which, after most desperate efforts, succeeded in establishing themselves on the ramparts; but the other two were completely unsuccessful, and driven back with prodigious loss. Above two-thirds of the whole assailing force were killed, wounded, or taken in this attempt. A marble tablet recording the names of the brave men who fell on the occasion, has been erected in the church by the British officers. The place, however, was given up at the treaty of peace in May 1814. Bergen-op-Zoom is fifteen miles north of Antwerp, and twenty-two W.S.W. of Breda.

Bergerac ‖ Bergman.

BERGERAC, the capital of an arrondissement of the same name, in the department of Dordogne, in France. It is situated in a fertile plain, 27 miles S.S.W. of Perigueux, and on the right bank of the Dordogne, which is here crossed by a magnificent bridge of five arches. The town is well built, and has a communal college, tribunals of primary jurisdiction and commerce, a public library, and manufactures of paper, iron and copper ware, serges, hats, hosiery, leather, &c. It has an active trade with Bordeaux and Libourne in wines, grain, &c. The fortifications by which it was once surrounded were demolished in 1621, by order of Louis XIII. Pop. (1851) 9971. The arrondissement contains 13 cantons and 174 communes: pop. (1851) 118,247.

BERGHEM. See Berchem.

BERGMAN, Sir Torbern, a celebrated chemist and natural philosopher, born in 1735, at Catharineberg, in West Gothland. His father was receiver-general of the finances, and had destined him to the same employment; but nature had designed him for the sciences. His first studies were confined to the mathematics and physics; and the efforts that were made to divert him from science having proved ineffectual, he was sent to Upsal, with permission to follow the bent of his inclination. The fame of Linnæus at that time filled the whole kingdom; and Bergman was attracted by the splendour of his renown. He applied himself at first to the study of insects, and made several ingenious researches into their history, particularly into that of the genus of *tenthredo*, so much preyed on by the larvæ of the ichneumons, which nestle in their bowels. He discovered that the leech was oviparous; and that the *coccus aquaticus* is the egg of this animal, from which issue ten or twelve young. Linnæus, who had at first denied this fact, was struck with astonishment when he saw it proved. *Vidi et obstupui*, were the words he wrote at the foot of the memoir when he gave it his sanction. Bergman not only distinguished himself as an astronomer, naturalist, and geometrician: when the chair of chemistry and mineralogy became vacant by the resignation of Wallerius, he appeared as a competitor; and without having before this period paid any particular attention to chemistry, he published an able memoir on the preparation of alum. His dissertation was warmly attacked in the periodical publications, and Wallerius himself criticized it without reserve. The Prince Gustavus, afterwards king of Sweden, and then chancellor of the university, took cognizance of the affair; and after consulting two persons most competent to give him advice, and whose testimony went in favour of Bergman, he addressed a memorial, written with his own hand, in answer to all the grievances alleged against the candidate, to the consistory of the university and to the senate, who in consequence confirmed the wishes of his royal highness.

Bergman had now a hard duty to fulfil. He had to satisfy the hopes which had been conceived of him, to fill the place of Wallerius, and to put envy to silence. Accustomed to precision, he applied himself to experiments without paying any attention to theories; and he was the first to introduce

Bergmote || Berkeley.

into chemistry that process of analysis which is the essential antecedent of scientific system.

The continual application which Bergman bestowed on his studies proved ruinous to his health. He died in June 1784. The university of Upsal paid the most distinguished honours to his memory; and the academy of Stockholm consecrated to him a medal to perpetuate the recollection of his merits. His *Physical and Chemical Essays* were translated by Dr Edmund Cullen, and published in 2 vols. 8vo, in 1788; to which a third volume was added, published at Edinburgh in 1791.

BERGMOTE (Saxon *beorg*, a hill, and *mote*, a meeting), a term still applied to an assembly or court held upon a hill in Derbyshire for deciding controversies among the miners.

BERGOMUM, in *Ancient Geography*, a town of the Transpadana, built by the Gauls on their incursions into Italy; now *Bergamo*, in Lombardy.

BERIA, BERIE, BERRY, signifies a large open field; and hence those cities and towns in England, the names of which end with that word, are built on plain and open places, and do not derive their names from boroughs, as Sir Henry Spelman imagines. Most of our glossographers, in the names of places, have confounded the word *berie* with that of *bury* and *borough*, as if it had been the appellative of ancient towns; whereas the true sense of the word *berie* is a flat wide champaign, as is proved from sufficient authorities by Dufresne, who observes that *Beria Sancti Edmundi*, mentioned by Matthew Paris, 1174, is not to be taken for the town, but for the adjoining plain.

BERING, VITUS, of Copenhagen, a Latin lyric poet and historian, who flourished about 1650.

BERJA, a town and *partido* of Spain, province of Almeria, pleasantly situated in a valley of the Sierra de Gador, in the centre of the mining district, nine leagues from Almeria. It is well built, and contains one church, several monasteries, and three primary schools. Pop. 8709, chiefly employed in agriculture and mining. The principal traffic consists in the conveyance of the lead to the neighbouring port of Adra. One mine in the neighbourhood yielded from 1820 to 1841, 3,000,000 arrobas of ore.

BERKELEY, GEORGE, celebrated as the bishop of Cloyne, by which title he is almost as often referred to in philosophical writings as by his family name, was born at Kilcrin, near Thomastown, in the county of Kilkenny, and was the eldest son of William Berkeley, a cadet of the family of Earl Berkeley. On his monument it is stated that the year of his birth was 1679; and as he died in 1753, his life would thus be exactly contemporaneous with that of the great German philosopher Christian Wolf. In truth, however, he was born five years later, namely, on the 12th of March 1684. Sent very young to Kilkenny school, where Swift had already received his early education, he at the age of fifteen followed Swift to Trinity College, Dublin, and obtained a fellowship in 1707. It was there probably that he first became acquainted with his great Irish contemporary, who seems to have patronized him in some degree, and to have been the means of introducing him at a later period to Steele and Addison, Arbuthnot, and Pope.

He not only became a fellow in 1707; he also became an author, publishing a tract, *Arithmetica absque Algebra aut Euclide demonstrata*, which, however, appears from the preface to have been written three years before, at the age of twenty. But far more important, and indeed so important as to form an epoch in science, was the work which made its appearance in 1709, *An Essay towards a New Theory of Vision*, in which he is considered to have established the doctrine that the eye, no more than the ear, has any natural perception of space; all its perceptions of distance, of magnitude, and of situation, being acquired from the sense of touch. Mr Stewart has, in his Preliminary Dissertation, dwelt upon this theory at such length, that here it is only necessary to record that a great living authority in optics, Sir David Brewster, has questioned the truth of it; and that the question is interesting not only to the optician, but also far more to the psychologist, suggesting, as it does, many inquiries into the origin of our ideas generally. It may also be added, that twenty-four years afterwards (1733), Berkeley published a pamphlet in vindication of his theory, which is not, however, collected in his works.[1] Its title is, *The Theory of Vision, or Visual Language, showing the immediate Presence and Providence of the Deity, vindicated and explained. By the author of Alciphron, or, the Minute Philosopher.* Berkeley.

From this title it will be seen, that his early essay on the nature of vision contains the germs which afterwards fructified into the Berkeleian philosophy; and, especially, it will be seen that his speculations were not merely speculations, but had a noble practical object in view—the service of religion. The common opinion of him would seem to be, that he was a dreamer, who wrote romances in philosophy, and acted romances in religion. Judged by the standard of his own time, judged by any ordinary standard, his missionary zeal was certainly romantic; but in philosophy he was no romancer. The premises with which he starts, premises almost universally accepted amongst philosophers until the time of Reid, drag absolute idealism after them by a chain of the most irresistible logic; and the distinguishing characteristic of Berkeley's system is, that it is more reasonable than all previous ones, while it is at the same time applied to a more practical end.

This system was first promulgated (1710) in *A Treatise concerning the Principles of Human Knowledge, wherein the chief causes of error and difficulty in the sciences, and the grounds of scepticism, atheism, and irreligion, are inquired into.* We have quoted this title in full, that we may again call attention to the end which young Berkeley had in view,—it was to erect a polemic against the infidelity of the age. And he did so by denying, on the received principles of philosophy, the reality of an external world; thence arguing, that as there is no such world, we must, in order to account for the phenomena of sense, postulate a Deity continually acting on the minds of men, and necessitating certain perceptions. This scheme of objective or theistic idealism, it will be seen, is essentially distinct from the subjective or egoistic idealism of Fichte and the later German schools; it fraternizes with the idealism of Malebranche (to a certain extent), of Collier, and, in later times, of Schelling. (But for a more explicit statement of Berkeley's position, we must refer to Sir William Hamilton's *Discussions*, No. VI. p. 187, and to his *Dissertations* affixed to Reid's Works, pp. 816–819.)

Three years later, Berkeley went to London, and published a defence of his system in *Three Dialogues between Hylas and Philonous.* This was in 1713, a date which ought to be remembered, as it was in the same year that Arthur Collier first published in the *Clavis Universalis* his demonstration of the existence of the impossibility of an external world. So that, although Collier's speculations are quite independent of Berkeley's, they were published three years after; and Berkeley is thus the first philosopher who proposed a scheme of absolute idealism.

These dialogues, without making many converts, procured Berkeley many friends. He became intimate, chiefly

[1] This pamphlet seems to have been utterly unknown until it was lately discovered by Sir William Hamilton, who is in possession of a copy which he has kindly shown to the present writer, at the same time pointing out a footnote in the works of Berkeley (vol. i. p. 145, ed. 1784) where the existence of this pamphlet is expressly indicated.

Berkeley. through Swift, with the great wits of the time, contributing several essays to the *Guardian;* and before the end of the year accompanied the Earl of Peterborough to Italy, as chaplain and secretary of legation,—this also, on the recommendation of Swift, who seems to have taken a fancy to him. Berkeley's letters from the Continent are interesting in themselves, and as showing the sociability of his nature; he writes like a poet to Pope; he writes like a naturalist to Arbuthnot; he writes like a boon companion to Thomas Prior—his dear Tom. He returned next year to England, but soon again departed on a continental tour with a Mr Ashe. It was on this tour that he paid the celebrated visit to Malebranche, which ended in the death of the reverend father. On his former trip to Paris, he wrote to Prior,—"To-morrow I intend to visit Father Malbranch, and discourse him on certain points;" so that probably the present was not his first visit. On this occasion "he found the ingenious father in his cell, cooking in a small pipkin a medicine for a disorder with which he was then troubled, an inflammation in the lungs. The conversation naturally turned on our author's system, of which the other had received some knowledge from a translation just published. But the issue of the debate proved tragical to poor Malebranche. In the heat of disputation, he raised his voice so high, and gave way so freely to the natural impetuosity of a man of parts and a Frenchman, that he brought on himself a violent increase of his disorder, which carried him off a few days after." And no wonder, for Berkeley must easily have demolished the peculiar system of the father. The principles of Malebranche lead directly to absolute idealism, and Berkeley followed them to that result. But if absolute idealism be true, what becomes of the doctrine of transubstantiation? To save himself from heresy, the Catholic father had to bolster up his philosophy with an hypothesis, a mere hypothesis, which was, after all, but a vain attempt to frustrate the logical result of his speculations.

Berkeley returned to London in 1721. During his absence he had been elected senior fellow of his college, and on his return he took the degrees of bachelor and doctor in divinity. In the year following his fortune received a considerable accession from a very unexpected bequest. On his first going to London (1713), Swift introduced him to the family of the celebrated Vanessa, Mrs Esther Vanhomrigh, and took him often to dine at her house. It was the intention of this lady to have made the dean of St Patrick's her heir, but—her story is well known—she was disappointed in him, and left the whole of her fortune, about L.8000, to be divided equally between her near relation, Mr Justice Marshall, and Dr Berkeley. If money were an object to the philosopher, he shortly afterwards (1724) received a deanery, the value of which, about L.1100 a-year, his more worldly friends constantly, wonderingly, pityingly, contrasted with the paltry L.100 for which his missionary zeal very soon prompted him to exchange it. He resigned his fellowship, and became dean of Derry.

The scheme on which he had set his heart, and which the ease and comparative wealth of his deanery could not make him forego, was that of erecting a college in the Bermudas, to train pastors for the colonial churches, and missionaries for the American Indians. His position is thus described by Swift in a letter of recommendation to Lord Carteret, which we quote entire, as it conveys a very lively idea of what Berkeley's contemporaries thought of him:—"September 3. 1724. There is a gentleman of this kingdom just gone for England; it is Dr George Berkeley, dean of Derry, the best preferment among us, being worth about L.1100 a year. He takes the Bath in his way to London, and will, of course, attend your excellency, and be presented, I suppose, by his friend my Lord Burlington; and because I believe you will choose out some very idle minutes to read this letter, perhaps you may not be ill entertained with some account of the man and his errand. He was a fellow in Berkeley. the university here, and going to England very young, about thirteen years ago, he became the founder of a sect there, called the Immaterialists, by the force of a very curious book on that subject: Dr Smallridge and many other eminent persons were his proselytes. I sent him secretary and chaplain to Sicily, with my Lord Peterborough; and upon his lordship's return, Dr Berkeley spent above seven years in travelling over most parts of Europe, but chiefly through every corner of Italy, Sicily, and other islands. When he came back to England, he found so many friends that he was effectually recommended to the Duke of Grafton, by whom he was lately made dean of Derry. Your excellency will be frighted when I tell you, all this is but an introduction; for I am now to mention his errand. He is an absolute philosopher with regard to money, titles, and power; and for three years past, hath been struck with a notion of founding a university at Bermuda, by a charter from the crown. He hath seduced several of the hopefullest young clergymen and others here, many of them well provided for, and all of them in the fairest way of preferment; but in England his conquests are greater, and I doubt will spread very far this winter. He showed me a little tract which he designs to publish, and there your excellency will see his whole scheme of a life academico-philosophical (I shall make you remember what you were), of a college founded for Indian scholars and missionaries, where he most exorbitantly proposeth a whole hundred pounds a-year for himself, forty pounds for a fellow, and ten for a student. His heart will break if his deanery be not taken from him, and left to your excellency's disposal. I discourage him by the coldness of courts and ministers, who will interpret all this as impossible and a vision, but nothing will do. And therefore I do humbly entreat your excellency either to use such persuasions as will keep one of the first men in the kingdom for learning and virtue quite at home, or assist him by your credit to compass his romantic design, which, however, is very noble and generous, and directly proper for a great person of your excellent education to encourage." With much importunity, and after a tedious attendance, Berkeley at length obtained from the minister an assurance that his scheme would be supported, and it was in the happiness of this prospect that he penned these well-known lines:—

> "Westward the course of empire takes its way,
> The four first acts already past;
> A fifth shall close the drama with the day;
> Time's noblest offspring is the last."

Being now certain of success, Berkeley prepared to depart, and his first step was to marry. In August 1728, he married Anne, eldest daughter of the Right Hon. John Forster, speaker of the Irish House of Commons; and next month he set sail for Rhode Island. But in vain; the promises of the government were never fulfilled; he was left alone to fight his own battle; and after years of weary waiting beyond the sea, worried to death by creditors, all his expectations baffled, he returned to England sick at heart, having spent seven years of his prime, and the greater part of his fortune, in attempting to establish a scheme which, with all its simplicity, was yet too grand and too pure for the powers that then were to appreciate. His only earthly comfort seems to have been in his wife and child. In his wife he must have been very happy. When he married her, he wrote to his dear Tom, with a beautiful simplicity, "Her humour and turn of mind pleases me beyond anything I knew in her whole sex." Perhaps he was easily pleased; at least we gather as much from the way in which he talks of her painting and singing. Of her painting he says: "For my part, I think she shows a most uncommon genius;" the worthy bishop being then more than sixty years of age, and his wife having never handled a brush till six months before. Then of her singing: "My wife, I am told, is this

Berkeley. day inferior to no singer in the kingdom;" the bishop not being himself able to judge as having no ear for music, but seeming to take great delight in the music lessons, and summoning his family at four in the morning to the bass-viol and the Italian master.

By this time, however, Berkeley was settled in the bishopric of Cloyne, which he received in 1734 as a special mark of favour from the queen. It will be remembered that Queen Caroline was fond of listening to metaphysical conversations, and debates often arose in her presence between Clarke and Berkeley as principals, Hoadly and Sherlock as seconds. Hoadly had no sympathy whatever with Berkeley, blasting his philosophy and his Bermuda project as the reveries of a visionary. Sherlock, on the other hand, we are told, warmly espoused his cause, and particularly when *The Minute Philosopher* made its appearance, carried a copy of it to the queen as a triumphant testimony in favour of Berkeley. Her Majesty gave Berkeley the first bishopric that fell vacant. And so we find him happy and content as ever at the little village of Cloyne, admiring his own portrait painted by his wife after six months' lessons, and enjoying her singing without understanding a note of the music.

The Minute Philosopher was written against freethinkers of the Shaftesbury class. Soon after he became bishop of Cloyne, Berkeley wrote another polemic, *The Analyst*, against the mathematical sceptics, and especially against Halley, who had in conversation hazarded the remark, that the doctrines of Christianity are incomprehensible, and the religion itself an imposture; and he showed in this work that mysteries in faith are unjustly objected to by mathematicians, who admit much greater mysteries in science—the doctrine of fluxions for example. The most important of his remaining treatises are, *Queries proposed for the good of Ireland* (1735); a letter addressed to Roman Catholics during the rebellion of 1745; another to the Catholic clergy, entitled *A Word to the Wise* (1749); *Siris, a Chain of Philosophical Reflections and Enquiries concerning the Virtues of Tar-Water* (1744); and *Farther Thoughts on Tar-Water*, published 1752. This was his last performance for the press, and he did not survive it long. His health was delicate, he was somewhat of a hypochondriac, and drenched himself, perhaps hurt himself, with copious draughts of tar-water, the receipt of which he was constantly sending to his friends: "Give a heaped spoonful of common rosin, powdered in a little broth, &c. &c." Hypochondriac in his later days, tar-water was the absorbing idea of his mind; to drink it seemed to be in his eyes a moral obligation incumbent on all mankind. He advises a friend, in one letter, to shun late hours and drink tar-water; again he announces in another, that a spoonful half tar half honey is the remedy for cold. "My cholic," he says in a third letter, "is changed to gout and sciatica, the tar-water having drove it into my limbs." What a horrible complication of maladies campaigning it through his poor body,—stormed out of this fastness only to be driven into some out-of-the-way limb! So entirely did tar-water at this time seem to engage his highest intellect, that in the above-mentioned treatise entitled *Siris* he not only appears to regard it as the infallible all-heal of creation, but easily and naturally passes from the contemplation of it to the contemplation of the loftiest mysteries, so that, beginning with tar, he ends with the Holy Trinity.

In 1751, feeling the infirmities of age, and wishing to retire from the care of his diocese to superintend the education of his son, then nominated a student of Christ Church, that the revenues of the church might not be misapplied, nor the interest of religion suffer by the absence of the pastor from his flock, he sought to resign his bishopric, the annual income of which was not less at that time than L.1400. Failing of success in this application, he let the lands of his demesne at Cloyne on very easy terms, at the rent of L.200, which he directed to be distributed every year until his return among the poor housekeepers of Cloyne, Youghal, and Aghadda. He removed to Oxford in July 1752, being then in a very feeble state of health. "On Sunday evening, January 14. 1753, as he was sitting in the midst of his family, listening to a sermon of Dr Sherlock's, which his lady was reading to him, he was seized with what the physician termed a palsy of the heart, and instantly expired. The accident was so sudden, that his body was quite cold and his joints stiff before it was discovered, as the bishop lay on a couch, and seemed to be asleep, till his daughter, on presenting him with a dish of tea, first perceived his insensibility."

Berkeley || Berkshire.

The best edition of Berkeley's works is that published in London in 1784, 2 vols. 4to. (See Life of Berkeley, prefixed to his works. Tenneman says that it was written by Dr Arbuthnot. It was really drawn up by Dr Joseph Stock, most of the particulars having been furnished by the bishop's brother, the Rev. Robert Berkeley, D.D.) (E. S. D.)

BERKELEY, a market-town in the county of Gloucester, near the river Severn, on the Bristol and Gloucester railway. It is pleasantly situated on a gentle eminence, in a rich pastoral vale to which it gives name, and which is celebrated for its dairies, producing the famous cheese known as "double Gloucester." The town has a handsome church, a grammar-school, town-hall, market-house, and some trade in timber, malt, and cheese, by means of the Gloucester and Berkeley canal. Berkeley was the birthplace of the celebrated Dr Jenner, whose remains are interred in the church. Market-day Wednesday. Pop. (1851) 949.

Berkeley Castle, on an eminence S.E. of the town, is still in good preservation. This magnificent structure was built in the reign of Henry I., but it suffered considerably during the civil wars of the seventeenth century. It is still one of the noblest baronial castles extant in England. It is noted as the scene of the most barbarous murder of Edward II.

BERKHAMSTEAD, GREAT, a market-town of England, in the county of Herts, 26 miles N.W. of London, on the Junction canal and the London and Birmingham railway. It has a church, three chapels, an old market-house, a grammar and a free school, several almshouses, gaol, &c. Pop. (1851) 3395, chiefly engaged in straw-plaiting.

BERKSHIRE, one of the midland counties of England, bounded on the north by Oxfordshire and Buckinghamshire, from which it is separated by the Thames; on the east by Surrey; on the south by Hampshire; and on the west by Wiltshire. At the north-eastern corner this county comes slightly in contact with Gloucestershire. It is of a very irregular figure, its whole northern and eastern side being bounded by the sinuosities of the Thames. From east to west it extends about forty-two miles; from north to south, in its widest part, it is about thirty miles; but in its narrowest it is not more than seven. Area 451,040 acres.

The surface is generally level, diversified with undulations, though in some parts, as in the vicinity of the Thames, the hills rise rather abruptly, and give diversity and beauty to the scenery. This is especially the case near Farringdon, and on the opposite corner of the county near Windsor. Windsor forest was immortalized by Pope, at a time when its beauties were even less conspicuous than at present. The south and east sides of the county are well wooded, but the trees are not generally of great size, nor of the most valuable or picturesque kind. A line of chalk hills, a continuation of the Chilterns, runs east and west through the county at its broadest part, separating the two fertile valleys of the Kennet and the Thames. The highest land in the county is a range of chalk downs which extend from the banks of the Thames, between Reading and Wallingford, towards the north of Wiltshire, the highest point being White-Horse Hill, 893 feet high. The western and most elevated part is devoted to the pasture of sheep. The most celebrated breed is the well-known Southdown, which, together with a cross from

Berkshire. the old Notts and Leicester breeds, has almost entirely superseded the native stock.

The agriculture of the county varies much according to the locality. Wheat and beans are well cultivated: and a species of peat found on the banks of the Kennet yields ashes that are of great value to the soils near that river. More than one-half of the land is calculated to be under tillage, about one-quarter is pasturage, and the remainder consists of woodlands or uncultivated heaths. In the two valleys already mentioned, namely the vales of Kennet and White-Horse, dairy farming predominates. There is a large proportion of woodland in the south and east parts of the county. The district to the south of Reading, which has a mixed soil of clay, gravel, and sand, together with the fertile tract to the east of Wantage, yield rich crops of corn. Near Farringdon pigs are extensively reared, and the breed is celebrated. The eastern part of the county, though picturesque, is, with some exceptions, the most backward in its agriculture. The estate of Mr Pusey, M.P. for Berks, situated in the N.W. of the county, may be cited as one of the best examples of the improved system of farming. The farms are generally held from year to year. The condition of the labouring population is considered to have improved, and cottage rents are moderate.

Few parts of England are better supplied with the facilities of water communication than the county of Berks. It is connected by means of the Thames, which runs round or through it, on one hand with London and the sea, and on the other with the Severn at two separate points on that river; one through the Thames and Severn canal, with Gloucester; the other through the river Kennet and the Kennet and Avon canal, with Bath and Bristol. Besides the navigable rivers, it enjoys the benefit of the Wilts and Berks canal, which connects the Thames at Abingdon with the Avon at Trowbridge in Wiltshire, and comunicates with the Kennet and Avon canal. The other rivers, which all finally fall into the Thames, are the Ock, the Loddon, the Auburn, and the Lambourn.

The turnpike roads are generally good. The principal of these are the roads from London to Bath and Oxford, both of which enter the county at Maidenhead, and soon afterwards separate, the former running S.W. to Reading, the latter nearly due west to Henley. The Great Western railway passes through Berkshire from Maidenhead to near Swindon. The branch lines pass from Didcot to Oxford, from Reading to Newbury and Hungerford, from Reading to Basingstoke, on the South-Western railway, and from Reading to Guildford and Reigate, on the South-Eastern and Brighton railways. Besides these there is a branch of the South-Western line to Windsor, and another branch to that town from the Great Western.

The woollen manufacture was introduced into this county under the Tudors; and the story of the celebrated clothier, Jack of Newbury, has been handed down to the period when the establishments founded by him passed to the northern parts of the kingdom. At Abingdon some linen manufactures still linger. The copper smelted in Wales is conveyed to some large mills near Marlow, where it is rolled into sheets for coppering vessels. There are some few paper-mills near Newbury. The chief commerce of the county consists in the sale of its agricultural produce, and some transit trade, from being in the way of inland navigation between the two greatest English rivers, the Thames and the Severn.

The county is divided into twenty hundreds, containing twelve market-towns and 142 parishes, besides fourteen others chiefly or partially included in Berks. The county is in the diocese of Oxford and the ecclesiastical province of Canterbury. It forms an archdeaconry by itself, and is divided into the four rural deaneries of Abingdon, Newbury, Reading, and Wallingford. It is on the Oxford judicial circuit, and the assizes are held alternately at Reading and Abingdon. County courts are held at Abingdon, Farringdon, Hungerford, Maidenhead, Newbury, Reading, Wallingford, Wantage, Windsor, and Wokingham. Berlin.

Berkshire returns nine members to parliament, three for the county, two each for Reading and New Windsor, and one each for Abingdon and Wallingford.

At the five decennial enumerations the population of the county was as follows:—

Year.	Males.	Females.	Total.
1811.....	57,936	61,494	119,430
1821.....	65,832	66,807	132,639
1831.....	72,983	73,251	146,234
1841.....	80,582	81,177	161,759
1851.....	84,927	85,138	170,065

From the vicinity to the metropolis, the salubrity of the climate, and the general beauty of the country, few counties have more numerous seats of the nobility and gentry than are to be found in Berkshire. Among these stands pre-eminent the royal castle of Windsor, the favourite residence of our monarchs during many centuries; for although chiefly rebuilt in the reign of Edward III., it was originally constructed by William the Conqueror. See Windsor.

Antiquities, both Roman and Saxon, are numerous in various parts of this county. The Watling Street road of the former enters Berkshire from Bedfordshire at the village of Streatley, and leaves it at Newbury. Another Roman road passes from Reading to Newbury, where it divides into two branches, one passing to Marlborough in Wiltshire, and the other to Cirencester in Gloucestershire. A branch of the Icknield Street road passes from Wallingford to Wantage. Near Wantage is a Roman camp, of a quadrangular form; and there are other remains of encampments at East Hampstead near Wokingham, on White-Horse Hill near Pusey, and at Sinodun Hill near Wallingford. At Lawrence Waltham there is a Roman fort, and near Denchworth a fortress said to have been built by Canute the Dane, called Cherbury Castle. Dragon Hill is supposed to have been the burying-place of a British prince called Uter Pendragon, and near to it is Uffington Castle, supposed to be of Danish construction. On White-Horse Hill, in the same vicinity, is the rude figure of what is called a horse, although it bears a greater resemblance to a greyhound. It has been formed by cutting away the turf and leaving the chalk bare. It is said to occupy nearly an acre of land, and to have been executed by Alfred to celebrate a victory over the Danes in the reign of his brother Ethelred, in the year 872.

Berkshire comprehended the principality inhabited by the *Atrebates*, a tribe of people who originally migrated from Gaul before the island was divided into Roman provinces. Under that nation it formed part of *Britannia Prima*, and during the Saxon heptarchy was included in the kingdom of West Saxony. When Alfred divided the country into shires, hundreds, and parishes, it obtained the name of *Berocscire*, which was subsequently changed to that which it now bears. It was frequently the scene of military operations from the time of Offa down to the troubles in the reign of Charles I. During the civil war two battles were fought at Newbury. In 1643, after a siege, Reading was taken by the parliament forces, and the royalist party were expelled from the whole of the county except Wallingford.

Mineral springs are found at Cumnor and Sunninghill, and at the latter there are establishments for the reception of visitants. There is a strong chalybeate called Gorrick Well, near Luckley House, and some springs near Windsor of the nature of the Epsom waters.

The following are the principal towns in this county:—Reading, Newbury, Thatcham, Wokingham, Wallingford, Windsor, Abingdon, Wantage, Farringdon.

BERLIN, the capital of Prussia, and one of the most beautiful towns in Europe, is situated in the province of Brandenburg, regency of Potsdam, in Lat. 52. 30. N. and

Berlin. Long. 13. 24. E., in the middle of a sandy plain on both banks of the Spree, and is twelve miles in circumference. It is the ordinary residence of the king, and seat of the principal authorities.

It is divided into five large parts or quarters, which in German are called towns: Berlin, properly so called; Cologne, divided into Old and New Cologne; Friederichswerder, Friedrichstadt, Dortheenstadt or Neustadt. These are divided into 22 quarters or sections, which altogether comprehend 280 streets and 20 public places. The streets are broad and straight, crossing at right angles; the houses and even the greater part of the public buildings are of brick and plaster; and, from the flatness of the ground, the water in the drains stagnates, causing disagreeable and noxious odours, and the foot pavements are so narrow that two persons can scarcely walk abreast. Among the streets the principal are the Friederichstrasse, 4068 paces in length, and the magnificent street called Unter den Linden, 1032 paces long and 161 feet in breadth, planted with four rows of trees, and lined with superb edifices. This fine street is terminated on the west by the magnificent Brandenburg gate, erected in 1790, of colossal size, designed as an imitation of the Propylæum at Athens, and surmounted by a car of Victory drawn by four horses, which was carried away by the French in 1807, and brought back in triumph in 1814, when the Prussians bestowed upon the goddess the eagle and the iron cross which she now bears. Among the places or squares may be mentioned the Wilhelmsplatz, bordered with lime trees and ornamented with statues of the celebrated warriors of Prussia; the Lustgarten, planted with poplars and chestnut trees, and adorned by a statue of Prince Leopold of Anhalt-Dessau; the square of the Opera, with the statue of Blucher and other military heroes.

Berlin is encircled by a wall with sixteen gates, besides two *portes d'eau*. The ramparts serve for the purposes of police, but are useless as means of defence. There are 41 bridges, the most remarkable of which are the Lange-Brüche, adorned by a statue of Frederick William, and the Kœnigs-Brüche.

The city is embellished with many splendid buildings. Among the principal of these is the royal palace or schloss, imposing by its magnitude. In the White Hall, fitted up at an expense of L.120,000, the first meeting of the Prussian parliament was held (April 1847). The museum, begun in 1823 and finished in 1830 from designs by the architect Schinkel, is the finest edifice in the city. Opposite the entrance is a gigantic basin of polished granite, 22 feet in diameter, which was formed out of a vast isolated boulder which lay at Fürstenwald, about 30 miles from Berlin, and was conveyed in a flat-bottomed boat along the Spree to the city. The royal library is a tasteless heavy-looking building: it contains about 500,000 volumes, and nearly 5000 manuscripts, the former including Luther's Hebrew bible. This library is entitled to a copy of every work printed in the Prussian dominions. The arsenal, erected in 1695, forms a square each side of which is 268 feet in length, and previously to the revolution of 1848 contained a large store of warlike ammunition. When taken possession of by the mob it was plundered. The churches are numerous, but by no means handsome. Among these are the cathedral, an unsightly building; the Lutheran church of St Nicholas, the most ancient in the town; that of St Mary, with a steeple or tower 286 feet high; the Reformed church; the French church. Among the other buildings are the bourse, the opera-house, the charity and maternity hospitals, the invalid hotel, the custom-house, the mint, the post-office, the barracks, &c. The Thiergarten promenade is renowned throughout Germany.

It was not till 1851 that a monument was raised in honour of Frederick the Great. In that year an equestrian statue in bronze, modelled by Rauch, was erected in the Unter den Linden, opposite Prince William's palace and the university; the statue is 17 feet 3 inches in height, and stands on a granite pedestal 25 feet high. The monarch is represented in the costume he usually wore, and on each face of the pedestal are represented the great military commanders in the Seven Years' War, with other figures. This is one of the most magnificent monuments in Europe. A little out of the town, near the Halle gate, is a Gothic spire in bronze, raised to the memory of the brave men who fell in the campaigns of 1813–14–15. Berlin.

The university, founded in 1819, ranks among the first in Germany, especially as a medical school, and has the largest number of pupils next to that of Vienna. Before the late disturbances it was attended by nearly 1800 students. The number of professors, regular and extraordinary, amounts to 156, besides 8 teachers of languages and gymnastics. The number of students for the session ending June 1852 was 1409 (exceeding that of the previous year by 81), classed as follows:—

Theology	Natives,	128	
	Foreigners,	41	
			169
Law	Natives,	497	
	Foreigners,	123	
			620
Medicine	Natives,	210	
	Foreigners,	65	
			275
Philosophy	Natives,	210	
	Foreigners,	106	
			345
Total (besides unmatriculated auditors, 762),			1409

Berlin may be regarded as the principal centre of the intelligence of Germany, and it possesses to a great extent the means of intellectual advancement. Besides the university, there are six royal gymnasiums or high schools, numerous inferior academies, schools for trade, the fine arts, architecture, &c. All these institutions are under the direction of men of distinguished merit. The benevolent establishments, which are no less numerous, include seventeen hospitals, institutions for the deaf and dumb and for the blind, hospitals for orphans, &c.

Berlin is one of the first manufacturing towns in Germany. Its principal branches of industry—which supply the simplest wants as well as the delicacies of the most refined luxury—are porcelain, silks, linen and cotton stuffs, hosiery, ribbon-weaving, gunpowder, paper, tobacco, jewellery, clock-making, Berlin iron, &c. Cast-iron goods of all kinds are manufactured at the foundry outside the Oranienburg gate. The finer kinds of ornamental iron-work of Berlin are very celebrated. The navigation of the Spree, which communicates by means of canals with the Elbe and the Oder, and the numerous railroads and the different routes of which Berlin is the centre, promote the commerce of this town with the interior of the country and with Europe.

In 1688 the population of Berlin was about 18,000; in 1775 it had increased to 135,900; in 1816 it was 182,381; in 1838, 290,797; and in 1849, 423,902—of whom, 22,748 were military, 220,874 males, 203,028 females, 398,727 Protestants, 15,532 Roman Catholics, and 9604 Jews. The number of dwelling-houses at this date was 9155. The denseness of the population arises from the custom of different families dwelling in the separate stories of the same house. In May 1852 the population was 446,931, exclusive of military. The total number of deaths in 1852 was 11,614. Of these 226 were by violence (of which 107 were suicides), and 2389 by bronchial affections and consumptions.

Among the many celebrated men to whom Berlin has given birth, may be mentioned the philosopher Baumgarten, the chemist Achard, the lawyer Albrecht, the diplomatist Ancillon, Tieck the poet, and the two Humboldts.

Berme || Bermudas.

The history of Berlin is very obscure. According to the most common opinion, Albert the Bear, Count of Anhalt, who took the title of Margrave of Brandenburg, founded the city. It increased and acquired importance under Waldemar of Anhalt, who died in the year 1319. It declined, however, considerably under the reign of the princes of the house of Luxembourg; but under Frederic of Hohenzollern, elector of Brandenburg, Berlin entered on a new era of prosperity. Lutheranism, adopted by the house of Brandenburg under the reign of Joachim II. (1535–1570), gave an increasing impulse to arts and sciences, trade, commerce, and everything which makes towns flourishing and a people happy. In spite of a terrible pestilence which ravaged the town in 1582, and the disasters of the Thirty Years' War, Berlin continued to advance in prosperity. It is to Frederick William, and especially to Frederick the Great, that the capital of Prussia is indebted for its prosperity and magnificence. The two most remarkable events connected with the history of the town are its occupation by the Austrians in 1760, and by the French in 1806, after the battle of Jena. It contains no remains of the mediæval period, but is entirely indebted to modern art for its present magnificence.

BERME, in *Fortification*, a space of ground left between the rampart and the fosse, designed to receive the ruins of the rampart, and prevent their filling the fosse. It is sometimes palisadoed, and in Holland it is generally planted with a quickset hedge. It is also called *liziere, relais, foreland, retrait, pays de souris*, &c.

BERMUDAS, or SOMERS'S ISLANDS, a cluster of small islands in the Atlantic Ocean, about four hundred in number, but for the greater part so small and barren that they possess neither inhabitants nor name. The north part of these islands is situated in Long. 62. 28. W. Lat. 32. 34. N. Their discovery resulted from the shipwreck of Juan Bermudas, a Spaniard (whose name they now bear), when on a voyage from Old Spain to Cuba with a cargo of hogs, about the year 1522. Henry May, an Englishman, suffered the same fate in 1593; and lastly, Sir George Somers shared the destiny of the two preceding navigators in 1609. Sir George was the first who established a settlement upon them, but he died before he had fully accomplished his design. A company of 120 persons was formed in Virginia, sixty of whom, under the command of Mr Henry More, proceeded to the island; and an accession of inhabitants was gained during the civil wars, many having sought a refuge from the tyranny of the ruling party in this distant sanctuary.

Of the vast number of islands composing this archipelago, not above twelve are inhabited. The names of the principal of these are St George, Hamilton, St David, Cooper, Ireland, Somerset, Nonsuch, and Long and Bird Islands. These are closely connected, and in their characteristic features so similar, that they may be considered and described as one island. The coast is of the most dangerous description, being thickly studded with rocks, which appear and disappear with the ebb and flow of the tide. A landing is never attempted without a pilot. The extreme length of the colony, from St Catherine's Point on St George's to the western extremity of Bermudas, is not more than twenty miles; but the road continues round the Great Sound to the N.E. point of Somerset, making the distance 24 miles. The greatest breadth from north to south by land is about one mile and a half, and the whole superficies is 12,161 acres. The harbour of St George's Island has water and space enough to accommodate the whole British navy; yet until, by the labour of the convicts and submarine blasting, the entrance was deepened and enlarged, it was so obstructed by rocks that the harbour was almost unapproachable. The appearance of Bermudas at first sight is highly romantic; but a closer inspection does not justify the first impression, and the prospect becomes very monotonous. Broad fields of barren rock, and tracts of evergreen cedar, are scattered over the whole island, which is traversed by numerous sheets of salt water. There are a great number of caves, some of which pierce far into the land. Beautiful varieties of stalactites and stalagmites fret these subterranean halls. Bermudas is still greatly behind in agriculture, although capable of producing all varieties of vegetables. In 1827 there was only one plough in the whole colony, the spade being in more general request. Since 1843, however, the produce of the land has largely increased. The neglect of internal resources may be ascribed to the facility with which supplies are received from America, and also to the great variety of excellent fish with which the shores abound, withdrawing the attention of numbers of the lower orders from the cultivation of the soil. The whale is an annual visitor of the coast; the fishing of which being a lucrative employment, is another inducement to neglect the spade. The soil is very fertile in the growth of esculent plants and roots, such as potatoes, onions, cabbages, carrots, turnips, pease, French beans, &c. The citron, sour orange, lemon, and lime, grow spontaneously in great luxuriance; but the apple and the peach arrive at no perfection. Medicinal plants, such as castor, aloe, and jalap, grow to great perfection without culture; and coffee, indigo, cotton, and tobacco, are also spontaneous products. A great quantity of arrow-root is raised, which is considered of first-rate quality. Few oxen or sheep are reared in the colony, these being supplied from North America. Bermudas possesses no fresh-water streams, and only a few wells, the water of which is brackish; but there are a great many tanks, which fill during the rainy season, and afford the principal supply of water. Vegetation is very rapid on these islands, there being but little variety of temperature in the different seasons. Spring may be said never to forsake them, and accordingly the fields and forests are clad with a mantle of perpetual green. The climate, however, is by no means healthy, and only a short residence is necessary to foster the germs of constitutional disease. The yellow fever and typhus are often destructive. In 1853 the former of these diseases made dreadful ravages.

Bermudas.

There are only two small towns in Bermudas, St George's and Hamilton, each of which has a mayor and other civic officers. The former was the capital until Sir James Cockburn removed the senate and courts of justice to Hamilton, which, being centrally situated, is much more convenient. There is little display of architectural taste in these places, the buildings being both disproportioned and irregularly huddled together. They are built of sandstone, veins of which are everywhere found. Limestone is also abundant. There are three signal stations, one at St George's, another at Mount Langton, and a third at Gibb's Hill. At each of these a small party of soldiers is stationed. A dockyard, prisons, a lighthouse, a mansion for the naval commissioner, and several other public works, have been built, for the erection of which about 1700 convicts are employed. The annual cost of the maintenance of these people is about L.20 a-head. The churches and schools are numerous. Government has made great efforts to encourage education in the colony; but these have been feebly seconded by the inhabitants, especially the whites. In the admiralty school at Ireland Island, the white and coloured children are instructed together; but in other parts of the colony prejudice as yet runs too high for such a combination. The result is, that the children of the poorer class of whites, who will not associate with the coloured class, are either sent to small schools badly conducted, or not sent to school at all. It has been found that the coloured people are not only more eager to procure a good education for their children, but are better able to pay for it, than the lower class of whites.

The revenue in 1849 was L.11,914; in 1850, L.12,630; to which is to be added the annual parliamentary grant of L.4049. The expenditure in 1849 was L.17,426; in 1850,

Bernadotte || Bernard.

L.16,227. The military expenditure in 1850 was L.70,160. The charge for 1566 prisoners during 1850 was L.34,595. The value of imports in 1849 amounted to L.132,733; in 1850, to L.130,501: of these the larger proportion was from the United States. The exports for 1849 amounted to L.15,315; for 1850, to L.19,960.

The population in October 1843 was 9934; on the 1st January 1851, 11,092,—consisting of 4669 whites; males 1965, females 2704. The coloured population amounted to 6423; males 2832, females 3591. The increase of white population since 1843 has been at the rate of one-eighth per annum; the increase of the coloured population at two-eighths. The great disproportion between the males and the females among the whites is attributed to the increasing emigration of the young men.

BERNADOTTE, afterwards CHARLES XIV., king of Sweden and Norway, was the son of a lawyer at Pau in Béarn, and was born Jan. 26. 1764. His original name was Jean-Baptiste-Jules Bernadotte. He was destined by his parents for the law; but he chose the profession of arms, and enlisted in 1780 as a private in the royal marines. When the revolution swept away the arbitrary distinction of classes, and opened up to all alike the path of preferment, the abilities of Bernadotte were speedily acknowledged. In 1792 he was made a colonel; in the following year a general of brigade; and soon after a general of division. In the campaigns of the Rhine and of Italy his military talents found ample scope for display; and his diplomatic abilities had also been tested as ambassador at the court of Vienna. During Buonaparte's absence in Egypt, Bernadotte was appointed minister of war. He re-organized the whole army, and prepared the way for the conquest of Holland. Notwithstanding the rivalry that all along existed between him and Napoleon, Bernadotte was made a marshal on the establishment of the empire. He was also nominated to the government of Hanover, and took part in the campaign of 1805 at the head of a force of 20,000 men. At the battle of Austerlitz he covered himself with glory; and in 1806 he was created prince of Ponte-Corvo. In 1810 the assembled states of Sweden nominated him as successor to Charles XIII. of Sweden, a distinction for which he was scarcely less indebted to his nobility of character than to his military talents. The jealousy exhibited by Napoleon on that occasion, and Bernadotte's politic rebuke, are characteristic of the two men. "What!" said Bernadotte, "would you make me greater than yourself, by compelling me to refuse a crown?" Napoleon could only reply, "Go—our fates must be accomplished."

As crown-prince of Sweden, Bernadotte devoted his whole energies to the welfare of his adopted country. Owing to the infirmities of the king, he was intrusted with the entire conduct of the government. On the death of Charles XIII., in February 1818, Bernadotte ascended the throne. The events of his administration, so conducive to the prosperity of that country, are given in the article SWEDEN. He died at Stockholm, March 8. 1844, at the age of seventy-nine; and left an only son, Oscar, who succeeded him. See SWEDEN.

BERNARD, ST, the first abbot of Clairvaux, was the third son of Tescelin of Fontaine in Burgundy, where he was born in 1091. He acquired so great a reputation by his zeal and abilities, that all the affairs of the chuch appeared to rest upon his shoulders, and kings and princes seemed to have chosen him as general arbitrator of their differences. It was owing to him that Innocent II. was acknowledged sovereign pontiff, and that, after the death of Peter Louis the anti-pope, Victor, who had been named his successor, voluntarily abdicated the dignity. Bernard convicted Abelard at the council of Sens, in the year 1140; he opposed the monk Raoul; he persecuted the followers of Arnold of Brescia; and, in 1148, he caused Gilbert de la Porvicé, bishop of Poitiers, and Eonde l'Etoile, to be condemned in the council of Rheims. By such zealous behaviour he verified, according to Bayle, the interpretation of his mother's dream. She had dreamed, when with child of him, that she should bring forth a white dog, whose barking should be very loud. Astonished at this dream, which she was unable to unriddle, she consulted a monk, who said to her, "Be of good courage; you shall have a son who shall guard the house of God, and bark loudly against the enemies of the faith." But St Bernard went far beyond the prediction; for he barked sometimes against chimerical enemies, and was more successful in exterminating the heterodox than in putting down infidels, although he attacked the latter, not only with the ordinary arms of his eloquence, but also with the extraordinary weapon of prophecy. He preached the crusade under Louis the Younger, and added greatly to the troops of the crusaders. But all the splendid visions with which he had flattered the people were disappointed by the event; and when it was alleged that he had hurried a vast number of Christians to slaughter without sharing the dangers himself, the saint alleged in his defence that the sins of the crusaders had destroyed the efficacy of his prophecies. He is said to have founded 160 monasteries, and to have wrought a prodigious number of miracles. He died August 20. 1153, aged sixty-three. Of the numerous editions of his works, the best is that of Father Mabillon, printed at Paris in 1690, in 2 vols. folio, which also contains the biography of St Bernard written by his secretary and disciple Geoffrey.

Bernard.

BERNARD, *Dr Edward*, a learned astronomer, linguist, and critic, was born at Perry St Paul, near Towcester, May 2. 1638, and educated at Merchant-Tailors' school, and St John's College, Oxford. On entering the university, he was already master of all the elegancies of the Greek and Latin tongues, and not unacquainted with the Hebrew. He there applied to the study of history, philology, and philosophy, and mastered the Hebrew, Syriac, Arabic, and Coptic languages; after which he studied mathematics under Dr Wallis. Having taken the degrees of bachelor and master of arts, and afterwards that of bachelor of divinity, he went to Leyden to consult several Oriental manuscripts left to that university by Joseph Scaliger and Levinus Warnerus. On his return to Oxford he collated and examined the most valuable manuscripts in the Bodleian library, and became engaged in a very extensive correspondence with the learned of most countries. In 1669, when the celebrated Christopher Wren, Savilian professor of astronomy at Oxford, was appointed surveyor-general of His Majesty's works, and obliged to spend much of his time in London, he obtained leave to name Bernard as his deputy at Oxford. In 1676 he went to France as tutor to the dukes of Grafton and Northumberland, sons of Charles II. by the duchess of Cleveland, and then living with their mother at Paris; but the simplicity of his manners not suiting the gaiety of the duchess's family, he returned about a year after to Oxford. He composed tables of the longitudes, latitudes, right ascensions, and declinations of the fixed stars; Observations in Latin on the Obliquity of the Ecliptic; and several other pieces inserted in the *Philosophical Transactions*. He also wrote, 1. A Treatise on Ancient Weights and Measures; 2. *Chronologiæ Samaritanæ Synopsis*, in two tables; 3. Testimonies of the Ancients concerning the Greek Version of the Old Testament by the Seventy; and several other learned works. This learned and pious man died January 12. 1696, in the fifty-eighth year of his age, leaving behind him a number of manuscripts which are now deposited in the Bodleian library. His biography has been written by Dr Smith.

BERNARD, *James*, professor of philosophy and mathematics, and minister of the Walloon church at Leyden, was born at Nions, in Dauphiné, September 1. 1658. Having studied at Geneva, he returned to France in 1679, and was chosen minister of Venterol, in Dauphiné, whence he was

Bernard ‖ Bernay.

removed to the church of Vinsobres. The persecution against the Protestants obliging him to abandon his native country, he retired to Holland, where he was well received, and appointed one of the pensionary ministers of Gauda. In July 1686 he commenced his *Histoire Abrégée de l'Europe*, which he continued monthly till December 1688. In 1692 he began his *Lettres Historiques*, containing an account of the most important transactions in Europe; and he carried on this work till the end of 1698. It was afterwards continued by other hands, and consists of a great number of volumes. When Le Clerc discontinued his *Bibliothèque Universelle* in 1691, Bernard wrote the greater part of the twentieth volume, and the five following volumes. In 1698 he collected and published *Actes et Négociations de la Paix de Ryswic*, in four volumes 12mo. In 1699 he began the *Nouvelles de la Republique des Lettres*, which continued till December 1710. Having acquired great reputation by his works, as well as by his sermons at Gauda and the Hague, he was unanimously elected in 1705 one of the ministers of the Walloon church at Leyden. About the same time he succeeded M. de Valder in the chair of philosophy and mathematics at Leyden; and the university presented him with the degrees of doctor in philosophy and master of arts. In 1716 he published a supplement to Moreri's Dictionary, in two volumes folio. The same year he resumed his *Nouvelles de la Republique des Lettres*, and continued it till his death, which happened on the 27th of April 1718. Besides the works above mentioned, he was the author of two excellent treatises, one on a late repentance, the other on the excellency of religion.

BERNARD, *Simon*, a celebrated French general of engineers, and aide-de-camp to Napoleon, was born at Dôle in 1779. Subsequently to the emperor's fall he emigrated to the United States, where he executed a variety of works, unequalled for magnitude, consisting of vast canals, numerous forts, and 1400 leagues of frontier fortifications. He returned to France, and in 1836 was secretary at war. He died in 1839.

BERNARD, *The Great St*, a celebrated mountain pass of the Pennine Alps, upwards of 8000 feet in height, between the Swiss canton of Valais and the valley of Aosta. Near the summit is the famous hospice, said to have been founded by St Bernard of Menthon in Savoy in 962, for the succour of travellers crossing the mountain. In their philanthropic labours the monks inhabiting the hospice have valuable assistants in their dogs, which are known as the St Bernard breed, and are noted for their extraordinary size and sagacity. In 1800 Napoleon crossed the Alps here at the head of an army of 30,000 men, with cavalry and artillery.

BERNARDINE, ST, of Siena, was born at Massa in Tuscany, in 1380. In 1404 he entered into a Franciscan monastery near Siena, and was afterwards sent to Jerusalem as commissary of the Holy Land. On his return to Italy, he preached with such applause that Ferrara, Siena, and Urbino applied to Pope Eugenius IV. to appoint him their bishop; but Bernardine declined the honour, accepting only the office of vicar-general of the Friars of the Observance for all Italy. He repaired and founded above 300 monasteries in that country, died in 1444, and was canonized by Nicholas V. in 1450. His works were published at Venice, 1591, 4 vols. 4to.; and at Paris, 1636, 2 vols. folio.

BERNARDINES, an order of monks founded at Citeaux in 1098, by Robert abbot of Molême, and reformed by St Bernard.

BERNAY, capital of an arrondissement of the same name in the department of Eure, France, is agreeably situated on the left bank of the Charentonne, 26 miles W.N.W. of Evreux. It is a town of great antiquity, and was at one time a fortified place. It was besieged by Duguesclin in 1378, taken by the English in 1418 and in 1421, and by the Admiral de Coligny in 1563. The fortress was razed in 1589. It has two fine old churches, a communal college, an hospital, and some precious remains of mediæval architecture. It has manufactures of woollen, linen, and cotton goods, and is noted as being the seat of the greatest horse fair in France, frequently attended by upwards of 40,000 persons. Pop. (1851) of town 7233, of arrondissement 77,202.

Bernburg ‖ Berne.

BERNBURG, a city, the capital of the duchy of Anhalt-Bernburg. It is situated on the river Saale, by which it is divided into two parts. It is the seat of the ducal courts of judicature, revenue, and other branches of administration. The sovereign residence or castle is on an elevation, surrounded with deep ditches, below which are the gardens and a fine orangery. It is a neat well-built capital in miniature, with a college, a mint, a gymnasium, orphan-house, and other public buildings. It has some trade in brewing, in snuff-making, earthenware, and ironmongery. Pop. 6100. Long. 11. 39. 23. E. Lat. 51. 47. 55. N.

BERNE, a canton in the centre of Switzerland, is situated between Lat. 46. 19. and 47. 30. N. Long. 6. 50. and 8. 28. E. It is bounded by the cantons of Soleure, Argau, Lucerne, Unterwalden, and Uri on the east; the Valais on the south; the cantons of Vaud, Fribourg, and Neufchatel on the west; and by the canton of Soleure and France on the north and north-west. Berne is the largest canton in Switzerland: its surface is estimated at 2562 square miles. The population in 1851 amounted to 457,921, of whom 403,769 were Protestants, and 54,044 Catholics. Nature has divided this canton into three regions, in which the climate varies with the elevation. In the southern part, called the Oberland, rise the Alps, and rich valleys lie stretched beneath them. Of the mountains, the highest are the Finsteraarhorn, the Schreckhorn, the Wetterhorn, the Eiger, and the Jungfrau. Of all Switzerland this region is the most interesting and attractive to travellers; below are fertile plains, a little above are green pastures, and higher still are gigantic glaciers, roaring waterfalls, and precipices with lofty peaks lost in the sky; below there is the temperate heat of southern climates, and above the coldness of the pole. Towards the north the ranges of the Jura are considerably lower. The central part is a fertile and carefully cultivated plain, abounding in corn and all sorts of fruits; the corn raised, however, is insufficient for the inhabitants, and large quantities require to be imported. The pastures in the Oberland and Emmethal are excellent, and produce the finest cattle: the latter valley is celebrated for its breed of horses, many of which are exported to France for draught and heavy-armed cavalry. It also produces cheese of excellent quality: the quantity made is estimated at 50,000 cwt. a-year, a great part of which is sent into Germany and Italy.

The principal river in the canton is the Aar, which receives numerous tributaries, the chief of which are the Emmat, the Birs, and the Doubs: the Emme forms the lakes of Bienne and Thun. The industrial productions are cotton, woollen, and flaxen stuffs, leather, watches, lace, and wood-work of all kinds. The rivers and roads which traverse the canton are favourable to commerce. The exports consist of hides, stuffs, *kirschwasser* cheeses, horses, and cattle. Iron, lead, and copper mines are wrought; there are also quarries of marble, lime, grit-stone, &c.; and the numerous forests furnish wood in abundance.

The canton of Berne is divided into 28 bailiwicks or prefectures. Its capital is Berne: the other chief towns are Bienne, Burgdorf, Thun, Porentruy, and Délemont. In the year 1798, 30,000 French invaded the canton, at which time Berne was deprived of nearly the half of its territory. A portion of it was restored in 1814; and there was likewise added to it the larger part of the bishopric of Bâle.

The canton of Berne occupies the second rank in the confederation, and returns twenty-three members to the national council. Its federal contingent is 104,080 Swiss francs, and 5824 men. For an account of the government and ju-

Berne ‖ Berners.

dicial system, in which great changes were made on the adoption of the new federal constitution in 1848, see SWITZERLAND.

BERNE, capital of the canton of the same name, and since 1849 the permanent seat of the Swiss government and diet, and the residence of the foreign ministers. It stands on a sandstone promontory formed by the winding of the river Aar, which nearly surrounds it, at an elevation of 1710 feet above the sea. Lat. 46. 57. N. Long. 7. 25. E. Berne was founded A.D. 1191 by Duke Berchtold of Zähringen, and gradually became a refuge for those who were oppressed by feudal exactions. In 1218 it was declared a free and imperial city by the Emperor Frederic. It thenceforward increased in importance, and excited the jealousy of the neighbouring states. They combined against it with the nobility of Berne, but were completely defeated in the battle near Laupen, June 21. 1339, by the Bernese, under Rodolph Von Erlach, to whose memory a bronze statue has been erected in the Münster-platz. In 1352 it joined the Swiss confederation. A fire destroyed the city in 1405; but it was afterwards rebuilt on the same plan. The Aar is here crossed by two fine stone bridges, one of which is 900 feet long, with a central arch 150 feet wide, and 93 feet high.

Viewed from a distance Berne presents a striking appearance. Situated within view of the snowy range of the Bernese Alps, the landscape is one of indescribable sublimity. The interior of the town itself is imposing. "It is impossible," says Stapfer, "for a stranger not to be struck with the breadth of the streets, and with the equal height and beautiful appearance of the houses, all of hewn stone, adorned with arcades, the pillars of which support the first floor; but he cannot help feeling a kind of sad solitude which pervades the almost deserted streets, the tide of passengers who traverse the thoroughfares being concentrated under the arcades. A very small number of striking edifices interrupt this row of singular habitations, all constructed on the same plan, and presenting in their general aspect the appearance of a large convent. Among these are the cathedral and the guild-hall in the middle of the city, on the southern and northern sides of the declivity on which Berne is situated; two magnificent hospitals; an asylum for orphans; a large corn-granary; a mint, and two towers for public uses. These are the only buildings which break the line of perfect republican equality which reigns in the rest of the town."

Berne possesses a university (founded in 1834), a great number of educational establishments and admirable charitable institutions, a valuable museum, a public library of 40,000 volumes, and several literary and scientific societies. Although, properly speaking, not a commercial city, it carries on some trade in cloth, printed calico, muslin, silk stuffs, silk and cotton stockings—articles fabricated in the manufactories of the town. The climate is severely cold in winter, the town being situated at so considerable an elevation above the level of the sea. The population, comprehending that of the villages under the town's jurisdiction, is reckoned at 27,000.

BERNE Machine, the name of an engine for rooting up trees, invented by Peter Sommer, a native of Berne.

BERNERA, an island on the western coast of Lewis, from which it is separated by Lochs Bernera, Burglow, and Roag. It is about 5 miles in length by 3 in breadth, and has a number of large upright stones, remains of a druidical structure. A small island off its north coast is called Little Bernera.

BERNERS, JULIANA, prioress of Sopewell nunnery, near St Albans, was the daughter of Sir James Berners, who was beheaded in the reign of Richard II. She was celebrated for her beauty, her spirit, and her passion for field sports. To her are attributed the treatises on "Hawkynge, Huntynge, and Fysshynge with an Angle; also a right noble Treatyse on the Lygnage of Cot Armours, endynge with a Treatyse which specyfyeth of Blasynge of Armys," printed in folio by Wynkyn de Worde in 1496. The first and rarest edition, printed at St Albans in 1486 does not contain the treatise on fishing. Juliana Berners is noticed by Ames and Wharton; and Hazlewood, who published an edition of the work (in facsimile of that of Wynkyn de Worde) in 1811, folio, London, has more lately examined, with industry and ability, the fair author's claims to figure as the earliest female writer in the English language.

Berneville ‖ Bernon.

BERNEVILLE, GILEBERT DE, a celebrated trouvère of the thirteenth century, is supposed to have been a native of Berneville, a small village near Arras. Twenty-six of his songs are preserved.

BERNHARDI, AUGUST FRIEDRICH, a learned German philologist, was born at Berlin in 1768, and died there in 1820. His *System of Language* (1801–3), and *Elements of the Science of Language* (1805), are works of great merit, as philosophic attempts to develop the science of vocal expression.

BERNI, FRANCESCO, an eminent writer of Italian jocose poetry, in very pure Tuscan, though often disfigured by licentious equivoques. His humour is broad, and his satire often cutting, though generally good-natured. He is best known in this country for his remodelling of the *Orlando Innamorato* of Boiardo, which was introduced to the English reader by the analyses and specimens by W. S. Rose in 1823. The best edition of Berni's *Rifaciamento* is that of 1545, which has been followed by Molini of Florence, in 1827.

BERNICLE. See ORNITHOLOGY, *Index.*

BERNICLE *Shell.* See MOLLUSCA, *Index.*

BERNIER, NICHOLAS, an eminent French musician, born at Mantes in 1664; died at Paris in 1734. He has left various works, and was esteemed one of the ablest composers of his time.

BERNIER, *François*, surnamed the *Mogul* on account of his travels and residence in the dominions of the Mogul, was born at Angers in France. After taking his degree of doctor of medicine at Montpellier in 1654, he visited Syria, Egypt, and the kingdom of the Mogul, where he became physician to Aurung-Zebe, and remained twelve years. Upon his return to France, he published the history of the countries he had visited, and spent the remainder of his life in composing various other works, particularly an abridgment of the philosophy of Gassendi, in 8 vols. 12mo. He died at Paris in 1688.

BERNIER'S ISLAND, a small island near the mouth of Shark's Bay, on the western coast of New Holland. This island consists of regular horizontal beds of sand and limestone, containing shells which sometimes appear at the height of 150 feet above the level of the sea. Vegetation is languid; the chief production being a species of cyprus, the long roots of which spread over the soil like net-work. Cormorants and sea eagles in small numbers are found in the island; and there are three species of lizards, one of which measures between four and five feet in length. A beautiful kangaroo is peculiar to this and two neighbouring islands, which, though timid, makes a vigorous resistance in defence of its young, few animals being more conspicuous for maternal affection. Lat. 24. 50. S. Long. 113. 5. E.

BERNINI, GIOVANNI LORENZO, commonly called the *Cavalier Bernin*, an Italian artist, born at Naples in 1598, was not only an architect and a sculptor, but also a painter and a mechanician. He was patronized by Pope Urban VIII. He lived during nine pontificates, and the works he executed at Rome are numerous, though of very questionable taste. He died in that city in 1680.

BERNON, elected abbot of Reichenau, on the lake of Zell, near that of Constance, in the year 1014, was celebrated as a poet, rhetorician, musician, philosopher, and divine. Besides other works, he wrote several treatises on music, particularly *De Instrumentis Musicalibus*, and *De*

Bernoulli. *Mensura Monochordæ;* but his most celebrated work is a treatise *De Musica seu Tonis.* This latter tract is part of the Baliol manuscript, and follows the Enchiridion of Odo. Bernon was highly esteemed by the Emperor Henry II., and succeeded so well in his endeavours to promote learning, that the abbey of Reichenau was as famous in his time as those of St Gal and Cluni. He died in 1048.

BERNOULLI, a name illustrious in the annals of the exact sciences, and belonging to a family of respectability, originally of Antwerp. During the oppressive and bigoted government of Spain, when the Flemings, like the expatriated Greeks with their stores of ancient learning, carried their arts, industry, and genius, to the less enlightened portions of Europe, this exiled family, driven from their liberties and soil for their attachment to the reformed religion, sought first an asylum at Frankfort in 1583, and afterwards at Basel, where they ultimately obtained the highest professional and civic distinctions. In the course of a single century not less than eight of its members successfully cultivated different branches of the mathematics, and by their personal labours contributed much to the extension of science and to the diffusion of correct knowledge over a great portion of Europe. The most celebrated of these distinguished men were James, John, and Daniel; but, for the sake of perspicuity, it may be proper to consider them nearly in the order of family succession.

I. BERNOULLI, *James*, was born at Basel on the 27th December 1654. He was educated at the public school of Basel, and, preparatory to his philosophical course in the university of the same city, he received private instruction from the learned lexicographer Hoffman, then professor of Greek. At the conclusion of his philosophical studies, some geometrical figures, which fell in his way, excited in him so ardent a passion for mathematical pursuits, that it was not to be checked even by the opposition and entreaties of his father, who wished him to be a clergyman. Like Pascal, whom he also resembled in intensity of religious feeling, he applied himself in secret to his favourite science, and by his unaided exertions became one of the most distinguished mathematicians of his time. In these forbidden labours he chiefly cultivated astronomy; while, with classic propriety, he chose for his device Phaethon driving the chariot of the sun, with the motto, *Invito patre sidera verso.*

In the spring of 1676 he visited Geneva on his way to the south of France, and subsequently extended his travels to England and Holland, without however relinquishing the studies of his choice. While at Geneva he taught a blind young lady several branches of science, and also how to communicate her ideas in writing; and he afterwards gave to the public, under the title of *A Method of teaching Mathematics to the Blind*, an account of the plan he had followed, which consisted in having recourse to the sense of touch, instead of that of sight.[1] At Bordeaux his Universal Tables on Dialling were constructed; and at London he had the happiness and advantage of being introduced into the philosophical meetings of Boyle, Hooke, Stillingfleet, and other learned and scientific men worthy of the age of Newton.

On his final return to Basel in 1682, he devoted himself to physical and mathematical investigations; and, in order to make the knowledge which he had acquired in travelling available, he opened a public seminary for experimental physics or mechanical philosophy,[2] which, from the interest of the experiments and the eloquence of the lecturer, became a source of attraction to his fellow-citizens. In the same year he published his essay on comets, *Conamen novi systematis Cometarum*, occasioned by the appearance of the comet of 1680, which had excited the attention of all the astronomers of Europe. This essay, and his next publication, entitled *De Gravitate Ætheris*, though both deeply tinged with the philosophy of Descartes, contain some truths not unworthy of the more correct philosophy of the *Principia.* But these, and several interesting papers in the *Journal des Savans* and *Acta Eruditorum* of that period, were only the preludes to greater labours and higher achievements. Bernoulli.

The pleasure which Pythagoras and Archimedes derived from their respective discoveries, was perhaps as vividly felt by the discoverers of the differential calculus. Newton and Leibnitz being independent discoverers, may be allowed to have had an equal share in that refined pleasure, as well as an equal claim to the merit of an invention which forms an epoch in mathematical science. But James Bernoulli, having had both the aid of his younger brother John, and the perusal of Leibnitz's new method of tangents and of maxima and minima, previously published in the Leipsic Transactions,[3] cannot be strictly called an independent discoverer; but, from his extensive and successful application of the calculus, he is well deserving of a place by the side of Newton and Leibnitz. As an additional claim of merit, he was the first to solve Leibnitz's problem of the isochronous curve, and to determine a curve mistaken by Galileo for a parabola—the catenarian (*la chainette*) or the curve formed by a chain suspended by its two extremities, and which he also showed to be the same as the curvature of a sail filled with wind. This curve, though proposed at first as a trial of Leibnitz's skill, is of much practical utility in regard to the nature of arches, and particularly of those of suspension.

These inquiries, like step following step, led to another interesting and useful curve, which, from being formed by an elastic plate or rod fixed at one end and bent by a weight applied to the other, he called the elastic curve, and which he also showed to be the same as the curvature of an impervious sail filled with a fluid such as water. In his investigations respecting cycloidal lines and different spiral curves, his attention was particularly directed to the loxodromic and logarithmic spirals; and his discoveries regarding the last, which possesses the remarkable property of reproducing itself under a great variety of conditions, induced him afterwards to make it the monument of his labours and the emblem of his hopes.

Whether in the frailty of envying the scientific honours of his younger brother, or in the better spirit of noble emulation, which then urged the torch of truth into brighter animation, he proposed to geometers in general, and to his brother in particular, the famous problem of isoperimetrical figures, with a promised reward for its solution. This problem engaged the attention of the British as well as continental mathematicians; and however little we may be prepared to expect such a result in the calm researches of abstract truth, it gave rise to a most unfortunate family quarrel. His brother John's solution being too hasty, and not quite satisfactory, a discussion arose, which, after much altercation, became a lasting feud, to be ended only by death.

Bernoulli. As the reward of merit, the mathematical chair of the university of Basel, vacant by the death of the learned Megerlin, had been conferred upon James not long after his return from his travels; and, in the discharge of the duties of his office he was so successful as to attract students from foreign parts, and to have pupils who became afterwards professors in some of the most celebrated universities of Germany. He was once made rector of the distinguished university of which he was a member, and he had other honourable distinctions bestowed on him. He and his brother John were the first two foreign associates of the academy of sciences at Paris; and, at the earnest request of the discriminating Leibnitz, they were both made members of the academy of Berlin. His fame, too, was increased by his posthumous work *De Arte Conjectandi*, which embraces the application of the doctrine of probabilities to moral, political, and economical subjects.

Three years previous to his official appointment at Basel, he had been offered a professorship at Heidelberg; but his union with an accomplished lady of his native city led him to decline the invitation. In this marriage he was happy; but his family, consisting of a son and daughter, though highly respectable in life, possessed little of the characteristic genius of their father. Intense application brought on infirmities, and a slow fever, of which he died on the 16th of August 1705, with all the resignation of a Christian, and all the firmness of a philosopher. Like another Archimedes he requested, previous to his death, that the logarithmic spiral should be engraven on his tombstone, with these words, *Eadem mutata resurgo;* elegantly alluding, by the properties of the curve, to the Christian's hope of the resurrection of the body.

In James Bernoulli were united many of the highest powers of the understanding with some of the best qualities of the heart. From a regard to truth he chose rather to be silent than eloquently wrong; and in religion he was equally removed from superstition and from free-thinking. With a bilious temperament, inducing that "philosophic melancholy" which is so often the attendant of true genius, his mind was peculiarly marked by elegance and simplicity, and by retentiveness rather than quickness. Like Plato, he combined the elegant exercises of the imagination with the more severe labours of the understanding; poetry with mathematics, and eloquence with philosophy.[1] He wrote elegant verses in Latin, in German, and in French; but although these were held in high estimation in his own time, it is on his mathematical works that his fame now rests. These are, 1. Jacobi Bernoulli Basiliensis Opera, Genevæ, 1744, 2 tom. 4to; 2. Jacobi Bernoulli Ars Conjectandi, opus posthumum: accedunt tractatus de Seriebus Infinitis, et epistola (Gallice scripta) de Ludo Pilæ Reticularis, Basiliæ, 1713, 1 tom. 4to. (See also Mémoires de l'Acad. de Paris, from 1702 to 1705; Journal des Savans; Acta Eruditorum; Eloges de Fontenelle; and Biographie Universelle.)

II. Bernoulli, *John*, was born at Basel on the 7th August 1667. His education was begun at six years of age; and his progress was such as to give a fair promise of future greatness. Having finished his literary studies, he was sent to Neufchâtel to learn commerce and acquire the French language. But at the end of a year, renouncing the enriching pursuits of the merchant for the less lucrative investigations of the philosopher, he returned to the university of Basel, where he was admitted to the degree of bachelor in philosophy. In a year after, at the age of eighteen, he obtained that of master of arts. His Bernoulli. thesis on the one occasion was *De Igne lambente*, written in Latin verse; and, on the other, *Que le Prince est pour les Sujets*, written in Greek verse.

In his mathematical education, it was his good fortune to have the able instruction of his elder brother James, whom he ultimately equalled in this congenial department of science. Chemistry, however, as well as mathematics, seems to have been the object of his early attention. In the year 1690 he published a chemical dissertation on effervescence and fermentation,[2] in which he endeavours to explain the phenomena of chemical action by the different figures of what he calls *active* and *passive* particles. But to have made a juvenile failure where so many have erred, and where some uncertainty yet remains, can scarcely infer any disgrace.

In the same year he went to Geneva, where he gave some instructions in the differential calculus to Fatio de Duiller, and afterwards proceeded to Paris, where he enjoyed the society of Malebranche, Cassini, De la Hire, and Varignon. With the Marquis de l'Hôpital he spent four months at his country residence in the study of the higher geometry, and the resources of the new calculus, of which he was an ardent promoter, and which he had the honour of imparting to his distinguished host. But his independent discoveries in mathematics are numerous and important. Of these it may be proper to mention the exponential calculus, and the curve called by him the *linea brachystochrona*, or line of swiftest descent, which he was not only the first to determine, but at the same time to point out the beautiful relation which this curve bears to the path described by a ray or particle of light passing through strata of variable density, such as our atmosphere.

On his return to his native city he studied medicine, a pursuit in some degree allied to his now favourite study of mathematics; and in 1694 he took the degree of M. D. On this occasion he maintained an ingenious thesis on muscular motion,[3] in which, however questionable may be the theory which he adopts respecting the contraction of the muscles, he displays a happy application of mathematical principles to the investigation of their motive power.

At this period he formed a connection by marriage with one of the oldest and most respectable families in Basel; and although he had already declined a professorship in Germany, he now accepted an invitation to be professor of mathematics[4] at Groningen. By his learned instructions he endeavoured to re-animate the then decayed state of mathematical science in that university; and in order to excite a taste for such pursuits, he gave a course of experimental physics to the public of that city.[5] During a residence of ten years in Groningen, his controversies were almost as numerous as his discoveries. An incidental expression regarding the resurrection, founded on the anatomical doctrine of a constant change in the particles of the body during life, brought on him a charge of heresy, which was preferred by a theologian of more zeal than wisdom.[6] Both his voice and pen, however, were exerted against his opponents in vindication of "his reputation, his religion, and his honour;" and in a medical dissertation *De Nutritione*, published at the time, he fully states his sentiments on this subject, and triumphs over his enemies with the resolution of *living down* such accusations.

Bernoulli. An electrical appearance of the barometer first observed by Picard, and considered by John Bernoulli under the name of mercurial phosphorus, or mercury shining in vacuo,[1] procured for him the notice of royalty, and engaged him in controversy. Through Leibnitz he received from the king of Prussia a gold medal for his supposed discoveries; while Hartsœker and some of the French academicians disputed the fact. If we could suppose the calm breast of his brother James to have been in any respect ruffled by this mark of royal favour, it might perhaps be considered as the remote cause of the family quarrel about the problem of isoperimetrical figures above mentioned. But be this as it may, the problem was proposed on this occasion; and we have no desire to use any softening when truth forbids it. Indeed his most ardent admirers must allow that, in his dispute with his brother, in his controversies with the English and Scottish mathematicians, and in his harsh and jealous bearing to his son Daniel, he showed a temper no less unfortunate for its possessor than calculated to impair the lustre of his character, and detract from the respect otherwise due to it. Having declined, during his residence at Groningen, an invitation to Utrecht, he however accepted, in 1705, the mathematical chair in the university of his native city, vacant by the death of his brother James; and here he remained till death, though flatteringly invited to higher emoluments in other distinguished universities.[2] His inaugural discourse was *De Fatis Novæ Analyseos et Geometriæ Sublimis*, which he himself so successfully applied in investigating the solid of least resistance, the problem of orthogonal trajectories, and various others both in pure and mixed mathematics. Successful in his official labours, at the request of the magistracy of Basel he applied himself to correct the relaxed discipline of the university, which was not indeed the least difficult task which he achieved.

He was several times a competitor for the prizes given by the academy of sciences of Paris; and his essays crowned with success were, on the laws of motion,[3] on the elliptical orbits of the planets, and on the inclination of the planetary orbits.[4] This last honour his son Daniel, the pupil of a better philosophy than the Cartesian, had the merit to divide with him; though the ambitious sensibility of the old man seems to have been hurt with what in other circumstances would have afforded him pleasure.

Some years after his return to Basel he published a valuable essay, entitled *Nouvelle Théorie de la Manœuvre des Vaisseaux*, which was occasioned by the questionable principles advanced by Renau on the same subject. But his works in pure mathematics are the permanent monuments of his fame, and must be studied to be fully appreciated. D'Alembert indeed acknowledges in gratitude, that "whatever he knew of mathematics he owed to the works of John Bernoulli." If his *Hydraulica*, one of the latest of his productions, was written, as has been supposed, in rivalry of the more original work of his son Daniel, it can only be considered as a proof of that infirmity from which great minds are not always free.

His health had at one period suffered much, as he says,[5] from those midnight hours of mental labour stolen from sleep; yet such was the vigour of his constitution, that he continued to pursue his usual mathematical studies till the age of eighty. He was then attacked by a complaint at first apparently trifling; but his strength daily and rapidly declined till the 1st of January 1748, when he fell asleep, Bernoulli. and thus expired without agony, or even a discomposing pang;[6] a death not unlike that of the illustrious chemist Black, who died with his usual meal of milk balanced in his hand, as if to show by an experiment how easy his exit from life had been.

He was a member of almost every learned society in Europe, and one of the first mathematicians of a mathematical age. With great warmth of temperament, he was as keen in his resentments as ardent in his friendships: a tender husband, though a severe brother; fondly attached to his family, yet disliking a deserving son; giving full praise to Leibnitz and Euler, yet blind to the surpassing excellence of Newton; sincere in his religion, though attacked by a theologian, and eulogised by a freethinker. The graphic if not faultless pencil of Voltaire has thus drawn his character:

> Son esprit vit la vérité,
> Et son cœur connut la justice.
> Il a fait l'honneur de la Suisse,
> Et celui de l'humanité.

His various writings were collected under his own eye by Cramer, professor of mathematics at Geneva, and published under the title of *Johannis Bernoulli Opera Omnia*, Lausan. et Genev. 4 tom. 4to; and his interesting correspondence with Leibnitz under the title of *Gul. Leibnitii et Johannis Bernoulli Commercium Philosophicum et Mathematicum*, Lausan. et Genev. 1745, 2 tom. 4to.

III. Bernoulli, *Nicholas*, the eldest of the three distinguished sons of John Bernoulli, was only a few months old when his father went to Groningen in the autumn of 1695.[7] His early indications of genius were cherished with all the fond attention usually bestowed on a firstborn. At the age of eight he could speak German, Dutch, French, and Latin. When his father returned to Basel he went to the university of that city, where, at the age of sixteen, he took the degree of doctor in philosophy, and four years after the highest degree in law.

During these pursuits the study of mathematics had not been neglected, as appears not only from his giving instructions in geometry to his younger brother Daniel, but from his writings on the differential, integral, and exponential calculus, and from his father considering him, at the age of twenty-one, worthy of receiving the torch of science from his own hands.[8]

Gladly embracing his father's permission to travel, he visited Italy and France. In the one he formed a friendship with Varignon, and in the other with Riccati, one of the first mathematicians of Italy, and the father of a family in some degree talented like the Bernoullis themselves; but ill health precluding him from reaping the advantages of more extended travelling, he returned to his native city.

The invitation of a Venetian nobleman, however, induced him again to visit Italy, where he resided two years, till his return to be a candidate for the chair of jurisprudence in the university of Basel. Disappointed in this object by the rather singular mode of election by lot, he was soon afterwards honourably appointed to a similar office in the university of Berne. Here he resided three years, respected and beloved, and with no other regret than what he felt on account of his separation from his brother Daniel; an attachment of kindred minds united

Bernoulli. in sentiment and pursuit, and deserving, in truth, the appellation of "par nobile fratrum." Both seemed fortunate in being appointed at the same time professors of mathematics in the academy of Petersburg; but this important office Nicholas enjoyed for little more than eight months. In the end of July 1726 he was cut off by a lingering fever, in the prime of life, and in the opening career of useful labour.

Sensible of the loss which the nation had sustained by the death of Nicholas Bernoulli, the Empress Catherine ordered him a funeral at the public expense; and, waiting at the academy, she presented her condolence in person to his surviving brother.[1]

Some of his papers are published in his father's works, and the others in the *Acta Eruditorum*, and the *Comment. Acad. Petropol.*

IV. Bernoulli, *Daniel*, second son of John Bernoulli, was born 9th February 1700, during his father's residence in Groningen. Like his father, Daniel was intended for a mercantile life; but, preferring a learned profession, he studied medicine, became a physician, and, following with hereditary ability and ardour his paternal steps, he rose to an eminence and fame worthy of his first and favourite appellation, "Son of John Bernoulli."

Taught by his father to regard mathematical learning as the sure foundation of all science and all practical art, his attention was early directed to geometrical studies, though the severity of his father's manner was ill calculated to encourage the first efforts of one of so sensitive a disposition; but fortunately, at the age of eleven, he became the pupil of his affectionate brother Nicholas.[2] Mathematics and medicine were equally the studies of his youth, and these he had the means of cultivating with particular advantage in Italy under Michelotti and Morgagni; the former being an able geometer, and the latter well skilled in several branches of physical science, as well as in anatomy. In such society he breathed a kindred element; and when he left Italy, he returned to his native country with well-won literary and scientific honours.

About this time, though only twenty-four years of age, he was invited to become president of an academy then projected at Genoa; but, declining this honour, he was, in the following year, appointed professor of mathematics at Petersburg. In this situation, although he enjoyed a competent salary, he still looked back with fond regard to the humble but equal lot of his native country. And on his resolving to leave Russia, the court of Petersburg not only augmented his salary, but granted him the half as a retiring pension, with the liberty of returning if he chose. This truly generous conduct made him for a time forego the gratification of a desire so peculiarly strong in a native of Switzerland. His health, however, allowing him only to remain three years longer, he returned to Basel, where in a short time he was appointed professor of anatomy and botany, and afterwards of experimental and speculative philosophy. In the useful and honourable labours of this office he spent the remaining years of his life, which are scarcely marked by any other events than the calm conquests of intellect, and the communication of valuable knowledge and good deeds to mankind.

He had previously published some medical and botanical dissertations, besides his *Exercitationes quædam Mathematicæ*, containing a solution of the differential equation proposed by Riccati, and which now bears the name of that celebrated geometer. In 1738 his *Hydrodynamica* appeared; and whatever may be its defects, it must be allowed to be at once an original and useful work. The equilibrium, the pressure, the re-action and varied velocities of fluids, are considered, not merely theoretically, but practically, with reference to the conveyance of water in pipes and canals, to machines for raising water, and also as a moving power in different mechanical operations. The concluding problem, illustrated by experiment, embraces an ingenious mode of propelling vessels by the reaction of water ejected from the stern.—*Hydrodynamica*, p. 30. Some of his experiments on this subject were performed in the presence of Maupertuis and Clairaut, whom the fame of the Bernoullis had attracted to Basel—a city famed for learning, and which had then, as D'Alembert remarks, become to the philosophers of France what Egypt had been to the philosophers of ancient Greece. Bernoulli.

With a success equalled only by Euler, his fellow-citizen, his friend, and successor at Petersburg, Daniel Bernoulli gained or shared no less than ten prizes of the Academy of Sciences of Paris. The first, on the construction of a clepsydra for measuring time exactly at sea, he gained at the age of twenty-four; the second, on the physical cause of the inclination of the planetary orbits, he divided with his father; and the third, on the tides, he shared with Euler, Maclaurin, and another competitor, whose only merit consisted in making a last effort to support the system of Descartes.

The problem of vibrating cords, which had been some time before resolved by Taylor and D'Alembert, became the subject of a long dispute between Daniel Bernoulli and his illustrious friend Euler. This discussion, however, was conducted with that generous spirit which soars above personalities, and with almost equal claims to praise; the one, in support of D'Alembert, displaying all the force of analysis; and the other, in defence of Taylor, using all the address of a mind fertile in resources.

In one of his early investigations on mechanics, he has given an ingenious though indirect demonstration of the problem of the parallelogram of forces; and in other papers, contained also in the Petersburg Memoirs, he has published researches of a higher character and of equal utility. His labours in the decline of life were chiefly directed to the doctrine of probabilities in reference to practical purposes, and in particular to economical subjects; to inoculation as an object of national interest, and to the duration of married life in the different sexes, and the relative proportion of male and female births. But in such speculations the premises often do not embrace all the existing circumstances; so that we need not be much surprised to find the results sometimes at variance with nature. His great object however was, in the spirit of true philosophy, to employ theory only as a means to investigate the secrets of nature, and to apply mathematics to explain with accuracy and certainty the phenomena of the universe.

By a regular and calm tenor of life, though of a delicate constitution, he retained his usual vigour of understanding till near the age of eighty, when his nephew James relieved him of his public duties. Being afflicted with a troublesome asthma, his retirement was confined to the society of a few chosen friends. In the spring of 1782 all his complaints were increased, and, after some days illness, this excellent man and true philosopher died like his father, in the repose of sleep.[3]

He was never married, owing, it is said, to a misplaced affection in youth. His manners were unaffected, and his society agreeable. His house, his table, and his dress, had nothing inconsistent with simplicity. Frugal without parsimony, and benevolent without ostentation, the wealth which might have been expended in selfish pleasure or

Bernoulli. idle show was judiciously employed in forming an endowment for poor students at Basel. Excluded by his professional character from the councils of the republic, he however received all the deference and honour of a first magistrate. He indeed enjoyed an esteem and respect seldom accorded to living worth. One of the first lessons which a parent taught his child was to bow to Daniel Bernoulli. Gratified as he must have been by this flattering regard of his fellow-citizens, he was yet wont to mention two incidents in his life as having afforded him the greatest pleasure; the accidental meeting and indirect approbation of Newton, and the solving of Kœnig's difficult problem, while he did the honours of the table for him.

Like his father, he was a member of almost every learned society of Europe, and he succeeded him as foreign associate of the academy of Paris. Several of his interesting investigations are contained in the earlier volumes of the Petersburg Memoirs; and his separately published works are, 1. *Dan. Bernoulli Dissertatio Inaugur. Phys. Med. de Respiratione.* Basil. 1721, 4to. 2. *Positiones Anatomico-Botanicæ.* Basil. 1721, 4to. 3. *Exercitationes quædam Mathematicæ.* Venetiis, 1724, 4to. 4. *Dan. Bernoulli Hydrodynamica.* Argentorati, 1738, 4to.

V. Bernoulli, *John*, the youngest of the three distinguished sons of John Bernoulli, was born at Basel on the 18th May 1710. He studied law and mathematics, and, after travelling in France, was appointed professor of eloquence in the university of his native city. In this office he continued five years, till the death of his father, whom he succeeded as professor of mathematics. He was thrice a successful competitor for the prizes of the academy of sciences of Paris. His prize subjects were, on the capstan, on the propagation of light, and on the magnet. The friendship of Maupertuis, who died under his roof while on his way to Berlin, was esteemed by him not the least of his honours. He himself died in 1790, at the age of eighty. His two sons, John and James, are the last noted mathematicians of the Bernoulli family.

VI. Bernoulli, *Nicholas*, cousin of the three preceding, and son of Nicholas Bernoulli, one of the senators of Basel, was born in that city on the 10th October 1687. He is frequently mentioned with approbation both by his uncle and Leibnitz in their epistolary correspondence. He visited England, where he was kindly received by Newton and Halley,[1] previously to his appointment at Padua to the mathematical chair which Galileo had once filled. But neither the classical recollections, nor the superior wealth of Padua, were sufficient to prevent his return to the freedom and happy mediocrity of his native city. At Basel he was successively professor of logic and of law, where he died on the 29th of November 1759. He was editor of the *Ars Conjectandi* of his uncle James. His own works are not published separately, but are contained in the *Acta Eruditorum*, the *Giornale de' Letterati d'Italia*, and the *Commercium Philosophicum*.

VII. Bernoulli, *John*, grandson of the celebrated John Bernoulli, and son of the second of that name, was born at Basel on the 4th December 1744. He studied at Basel and at Neufchâtel, and when thirteen years of age he took the degree of doctor in philosophy. His Thesis, *De Variolarum Insitione*, is still preserved in Haller's *Letters*. It gives a short history of inoculation, as well as the method of operation and manner of treatment which had recently and successfully been practised on himself.

The kindred studies of mathematics and astronomy were his early pursuits. When only nineteen years of age he was appointed astronomer royal of Berlin. Some years after, obtaining leave to travel, he visited Germany, France, and Bernoulli. England; and subsequently Italy, Russia, and Poland. On his return to Berlin he was appointed director of the mathematical department of the academy of that city. Here he died on the 10th July 1807, being, at the time of his death, a member of several of the learned academies of Europe.

He is a very voluminous and varied writer. His writings consist of several volumes of travels, besides astronomical, geographical, and mathematical works. In 1774 he published a French translation of Euler's Elements of Algebra at Lyons, in 2 vols. 8vo. He was a conductor of some of the periodical works of Berlin, and in the academical memoirs of that city are several of his papers on astronomical subjects. Those for the years 1803 and 1804 contain his observations and experiments on the cultivation of *zea mays* or Indian corn in Switzerland and Germany, and on its advantageous application to various economical purposes.

VIII. Bernoulli, *James*, younger brother of the preceding, and the second of this name, was born at Basel on the 17th October 1759. He displayed early talents, which were cultivated with the greatest care. Having finished his literary studies, he was, according to custom, sent to Neufchâtel to acquire the French language. On his return to his native city he studied law and took a degree.

The study of law, however, had neither alienated nor checked his hereditary taste for geometrical pursuits. The early mathematical lessons which he had received from his father were continued by his uncle Daniel, so as to give new vigour to his native predilection for the exact sciences. Such, indeed, was his progress in these studies, that at the age of twenty-one the directors of the university of Basel committed to him the duties of the chair of experimental physics, which his uncle's advanced years rendered him unable to discharge. But although he filled this important office with satisfaction, both to the directors and to his auditors, he did not succeed on his relative's death. The lot was capricious, and the voice of public opinion (by which almost all the important appointments at Basel were then decided) unfavourable. He had been formerly, too, an unsuccessful candidate for the chair of eloquence; so that, with perhaps a conscious feeling of unmerited neglect, he published on the present occasion a thesis *De Sublimi*.

This repeated disappointment, combined with the desire of travelling, so natural and so powerful in youth, induced him to accept the situation of secretary to Count de Brenner, which afforded him an opportunity of seeing a great part of Germany and Italy. In Italy he formed a friendship with Lorgna, professor of mathematics at Verona, and one of the founders of the Italian society for the encouragement of the sciences. He was also made corresponding member of the Royal Society of Turin; and, while residing at Venice, he was, through the friendly representation of Fuss, admitted into the academy of Petersburg, with the promise of promotion in the course of a year. In 1788 he was accordingly made one of the mathematical professors of that flourishing seminary, and in the following year he married a daughter of Albert Euler, son of the illustrious Euler. This marriage, which united names equally dear to science, and, from congeniality of sentiment, promised much happiness, was almost tragically dissolved in the space of two short months. Residence in the country, and the opportunity of bathing in the Neva, had given him a taste for that healthful but sometimes fatal exercise. Being an excellent swimmer, he was fearlessly enjoying this recreation, when at once he sunk without any appearance of danger or expression of pain. He was instantly

[1] *Com. Phil.* ep. 199.

Beroe || Berthollet

taken out by his brother-in-law, and every means of resuscitation applied, but without success. The opinion of the physicians was that his death had been occasioned by a shock of apoplexy. His constitution indeed was naturally delicate, and two years before he had suffered much from a nervous fever. His premature death at the age of twenty-nine was a source of deep regret, not only to his relatives, but to many whom he had attached to him by a character open, obliging, gentle, and modest.

Several of his papers are contained in the first six volumes of *Nova Acta Acad. Scien. Imper. Petropol.*, in the *Acta Helvetica*, in the *Memoirs of the Academies of Berlin and Turin*, and in his brother John's publications. He also published separately some juridical and physical theses, and a German translation of *Mémoires du Philosophe de Merian.* (T. A.)

BERNSTADT, a town of Prussian Silesia, twenty-two miles east of Breslau. It has a ducal castle, and manufactures of woollen and linen stuffs. Pop. 3600.

BEROE, a genus of ciligrade acalephous animals. See MOLLUSCA.

BERŒA, an ancient city of Macedonia, S.W. of Pella, on the river Astræus, a tributary of the Haliacmon. It is now known by the name of *Boor*. The Berœans are commended in Scripture for their reception of the Gospel. There was another Berœa in Syria, called also *Beroe*, and by the inhabitants *Berœa*. It is supposed to be identical with the modern Aleppo, or *Haleb*, so called from Chalep, the name given to Berœa by the Byzantine writers. There was a third town of this name in Thrace, between Philippopolis and Nicopolis.

BEROSUS, a priest of the temple of Belus at Babylon in the time of Ptolemy Philadelphus, and author of the History of Chaldæa, a work often cited by the ancients, and of which Josephus gives some curious fragments. The best editions of these fragments are by Richter, Lipz. 1825, and in Didot's *Fragm. Historicorum Græcorum*, vol. ii. Paris, 1848.

BERRE, a town of France, in the department of the Bouches-du-Rhone, and on a lake of the same name. It is remarkable for the quantity and excellence of the salt made there. Long. 5. 9. E. Lat. 43. 22. N. Pop. 1871.

BERRETINI DA CORTONA, PIETRO, historical and landscape painter, was born at Cortona in 1596, and, according to some writers, was a disciple of Andrea Commodi, though others affirm that he was the disciple of Baccio Ciarpi. This distinguished artist died in 1669. Some of his best works are in the Barberini Palace at Rome, and the Palazzo Pitti at Florence.

BERRETONI, NICOLO, historical painter, born at Montefeltro in 1637, was a disciple of Carlo Maratti, under whom he studied design and colouring, and attained such excellence that he excited the jealousy of his master. He died in 1682. (Lanzi.)

BERSARII (from *bersare*, to shoot with a bow, or from *bersa*, a fence), in writers of the middle ages, a term for hunters or sportsmen.

BERTHOLLET, CLAUDE LOUIS, one of the most distinguished chemists of the French school, was not a native of France, but born at Talloire, near Annecy, in Savoy, in 1748. He received his education first at Chambery, and subsequently in the provincial college at Turin, where he took his degree as a physician. On arriving at Paris, he soon became the medical attendant of Philip Duke of Orleans; and by the publication of a volume of chemical essays, which gained him such reputation that he was admitted, in 1781, into the Academie des Sciences. Through the interest of his royal patron he was appointed government superintendent of the establishment for the improvement of dyeing; and the result was the production of his very valuable essay *Sur la Teincture*, a work that first systematized and chemically explained the principles of the art of dyeing. This work has been well translated into English by Dr Wm. Hamilton, in two vols., 1791. Berthol-letia.

Berthollet early adopted the chemical views of Lavoisier, which he illustrated with great ingenuity, and contrasted with the phlogistic hypothesis of Stahl; and to the two former, assisted by Morveau and Fourcroy, we owe that beautiful system of chemical nomenclature to which subsequent philosophers have been so much indebted. Berthollet confirmed and extended the discoveries of Priestley on ammonia; discovered, among other curious substances, fulminating silver; and greatly extended our knowledge of that important substance the dephlogisticated marine acid of Scheele, for which the name of oxymuriatic acid was then proposed, and which is now termed chlorine. It was he who first proposed to apply it to bleaching—in 1785. During these researches he discovered the remarkable salt now called chlorate of potassa; and we owe to him also an excellent essay on the chemical constitution of soaps. But we cannot here attempt an enumeration of all the contributions to chemistry by this estimable philosopher: they are scattered through between eighty and ninety memoirs in the *Journal de Physique, Annales de Chimie, Memoires de l'Institut, and Memoires d'Arceuil*, from which they have been copied into all the philosophical journals of Europe.

At the commencement of the French Revolution the scarcity of saltpetre for the manufacture of gunpowder was much felt; and Berthollet was placed at the head of a commission for improving the processes for obtaining this important product within the territory of France. In this vocation he visited almost all France, and greatly improved and simplified the modes of obtaining and purifying saltpetre. Soon afterwards we find him one of a commission for improving the processes in the smelting of iron, and converting it into steel. The government fully appreciated his merits; and in 1792 he was appointed a director of the mint, in which he introduced several important improvements. In 1794 he was an active member of the committee on agriculture and the arts; while he filled the office of teacher of chemistry in the Polytechnic and Norman Schools of Paris, and was an active member in the remodelling of the National Institute in 1795.

When the victories of Buonaparte prostrated Italy, Berthollet and Monge were appointed by the convention as the heads of a commission to select from the spoils of Italy the choicest specimens of ancient and modern art, for the national galleries of Paris. This circumstance introduced Berthollet to the victorious general; and, in after years, led to his accompanying Buonaparte in the expedition to Egypt, where he was one of the most distinguished members of the Institute of Cairo. On the overthrow of the executive directory, Berthollet was made a senator, and a grand officer of the Legion of Honour. Under the empire he was created a count, and sat as a peer on the restoration of the Bourbons.

His last work was his curious essay on *Chemical Statistics*, in which he endeavoured to show that other causes than the mere force of elective attractions, as explained by Bergman, aided in producing chemical combinations; and he particularly showed how certain decompositions could be explained without the supposition of what was termed predisposing affinities, by the influence of insolubility, of aggregation, and of the mass of one of the ingredients. This ingenious theory was never generally adopted by chemists, the theory of definite proportions, and of opposite electric states, being supposed sufficient to explain chemical phenomena.

Berthollet was a man of great modesty and unostentatious manners. For some years he lived rather retired at Arceuil, especially after his grief for the misconduct and suicide of his only son. In 1822 he was attacked with a painful and lingering malady, which he bore with manly fortitude, and which ended in an enormous gangrene that put a period to his sufferings on the 6th of November of that year. (T. S. T.)

BERTHOLLETIA, a genus of plants of the nat. ord. of

Berthoud ‖ Bertinoro.

Lecythideæ. The lofty tree that produces the *Brazil or Para nut* is a Bertholletia. The kernels are contained in a spheroidal shell or case as large as a man's head, with four cells, in each of which are six or eight kernels. See *Plantæ Æquinoxiales* of Humboldt and Bonpland.

BERTHOUD, FERDINAND, chronometer-maker to the French admiralty, member of the Institute of France and of the Legion of Honour, was born near Neufchâtel in 1727. His father was an architect, and the son was intended to be bred to the church; but, having shown a taste for clockwork, an experienced workman was engaged to instruct him in its principles, and young Berthoud was afterwards sent to Paris to improve himself in the knowledge and practice of the art. He settled in Paris in 1745, and applied himself to the making of chronometers, an art which was then in its infancy. A chronometer is an accurately-made watch, whose chief peculiarity consists in a piece of mechanism intended to render the number of vibrations of the balance equal in equal times, at all the degrees of temperature to which the instrument is exposed; and the chronometer being a portable instrument, which can be used on ship-board, is by this mechanism made to move at a constant rate—say at the rate of mean solar time—so that it shows what hour it is at the meridian of Greenwich, if the chronometer, at the commencement of the voyage, was set to Greenwich time; whilst the observation of the height of the sun or of a star gives the hour, angle, and the hour at the place where the ship is; and the difference between these two times is the longitude of the ship. Fleurieu and Borda, by order of the French government, made a voyage from La Rochelle to the West Indies and Newfoundland for the purpose of trying the chronometers of Berthoud, and found that they gave the longitude with only a quarter of a degree of error, after a cruise of six weeks. Satisfactory results were also obtained in the expedition of Verdun, Borda, and Pingré, which was appointed to try his chronometers and those of Le Roy. An account of this expedition is published.

Sully, an English watch-maker established in Paris, was the first who in that city attempted the construction of chronometers for finding the longitude; and this he did in 1724. In 1736 the chronometers of the English artist Harrison were tried at sea. In France there were no chronometer-makers of note, from the first attempts of Sully, till Pierre le Roy and Ferdinand Berthoud, between whom there was some discussion about the priority of their discoveries and improvements. Ferdinand Berthoud's chronometers were long the most esteemed of any in France. Louis Berthoud, his nephew and successor, improved upon the machines of his uncle, and made them generally of a smaller size, so as to become more portable. Many further improvements have been made by the English chronometer-makers.

Berthoud was regular in his habits, and retained the use of his faculties to the last. He died of hydrothorax, at his country house, in the Valley of Montmorency, in 1807, at the age of eighty. The principal of his published works are *Essai sur l'Horlogerie*, 1786, 2 vols. 4to; two Tracts on Chronometers, 1773; *De la Mésure du Temps*, 1787, 4to; *Les Longitudes par la Mésure du Temps*, 1775, 4to; a Tract on Chronometers, 1782, 4to; *Histoire de la Mésure du Temps par les Horloges*, 1802, 2 vols. 4to; *L'Art de conduire et de régler les Pendules et les Montres* 1760, 12mo. This tract contains directions suited to general readers for regulating clocks and watches: it has gone through several editions. (W. A. C.)

BERTINORO, a city in the delegation of Forli in Italy, in the papal dominions, the seat of the bishop of the united dioceses of Forlempopoli and Bertinoro. It stands on a hill, below which the river Ronco flows, and is celebrated for the excellence of its wine. It contains about 4000 inhabitants. Long. 12. 2. 30. E. Lat. 44. 8 34. N.

Berwick ‖ Berwickshire.

BERWICK, THE DUKE OF, was a natural son of James II. by Arabella Churchill, sister to the great Duke of Marlborough. "The youth, named James Fitzjames (Macaulay's Hist. of Eng., vol. ii. p. 326), had as yet given no promise of the eminence which he afterwards attained; but his manners were so gentle and inoffensive that he had no enemy except Mary of Modena, who had long hated the child of the concubine with the bitter hatred of a childless wife. A small part of the Jesuitical faction had, before the pregnancy of the Queen was announced, seriously thought of setting him up as a competitor of the Princess of Orange. It does not appear that this absurd design was ever countenanced by the king. The boy, however, was acknowledged; and whatever distinction a subject not of the royal blood could hope to attain were bestowed on him. He had been created Duke of Berwick; and he was now loaded with honourable and lucrative employments, taken from those noblemen who had refused to comply with the royal commands." At the revolution of 1688, he became an exile with his father in France, where he was recommended to the court by his superior merit. He was created marshal of France, knight of the Holy Ghost, duke and peer of France, grandee of Spain, and commander-in-chief of the French armies; nor were these honours and employments greater than his services merited. He lived in an age when the Prince of Orange and many other great generals commanded against him; yet his reputation as a warrior suffered no eclipse by the comparison; while the victory of Almanza, which secured Spain to the Bourbon dynasty, stamped his character as a great and successful commander. His courage was cool and steady; and he was eminently remarkable for entire self-possession in all circumstances, even the most critical;—watchful, cautious, and persevering; ever ready to take advantage of a fault or an oversight committed by an antagonist, yet, throughout his whole career, frugal of the blood of his soldiers, and anxious that it should not on any occasion be wantonly or unnecessarily shed. The system of discipline he maintained was rigid; and although the wants of the soldier were scrupulously attended to, no commander ever punished excesses with greater severity.

The Duke of Berwick was much blamed by the more zealous and violent adherents of the Stuart family for not being sufficiently attached to the Jacobite party, which was that of his own family. But on a cool examination of his actions it will appear that his behaviour in this particular was, like the rest of his conduct, equally sensible and just. When he accepted of employments, received honours and dignities, and became naturalized in France, he considered it his duty to become a Frenchman in reality, and to be regulated in regard to the cause of the Stuarts according to the will and pleasure of the sovereign whom he served. But when commanded by his king to promote the views of the Stuart family, he acted with the greatest sincerity, and took the most sensible and effectual methods to serve his unhappy house. In a word, the Duke of Berwick was a man of high principle and honour; and he showed by his life and actions that moral integrity is compatible and consistent with the life of a statesman and a great general. He was killed by a cannon-ball at the siege of Philipsburg on the Rhine, in 1734, in the sixty-fourth year of his age.

BERWICKSHIRE, a county situated at the S.E. extremity of Scotland, is bounded by the German Ocean on the E.; by East Lothian on the N.; by a part of Mid-Lothian, but chiefly by Roxburghshire, on the W.; by the river Tweed, and that part of Roxburghshire which lies to the N. of the same river, on the S.; and by the township of Berwick on the S.E. On the S., the Tweed, in a winding course of about 35 miles, divides it, first, from the part of Roxburghshire which lies south of the river; secondly, from Northumberland; and thirdly, from North Durham. Its northern extremity is situated in N. Lat. 55. 58. 30.; and its southern

Berwick-shire.

point upon the Tweed is in 55. 36. 30. Dunse, its principal town, is situated nearly in the centre of the county. The extreme length of the county is 31¼ miles, and its extreme breadth 19½ miles. Its superficies is 446 square miles, or 285,440 acres, of which more than one-half is supposed to be arable, the remainder consisting of upland pasture and unreclaimed moor.

The county consists of two divisions distinguished from each other by well-marked natural features. The first comprises the Lammermuirs, a portion of that range of graywacké hills which, commencing with the bold promontory of St Abb's Head in this county, stretches quite across to the opposite coast of Scotland. The second consists of the level district which fills up the space between the base of the Lammermuir hills and the river Tweed. This comparatively level tract is called the *Merse*, a name which in various printed accounts is said to be derived from its ancient name the *March* or Border district. There is, however no derivation in the case, as *Merse* (mepɪc) is simply the old Saxon spelling of *Marsh*, a term which, however inapplicable to the district as we now see it, must have been singularly appropriate to it in its natural state. The valley of the Leader, called Lauderdale, forms a subdivision of the Lammermuir district.

The Lammermuirs present the well-known aspect of graywacké hills, viz., a succession of round-backed ridges with long unbroken slopes covered for the most part with a stratum of peat of varying thickness, bearing a rough herbage of heather, bents, and mosses. Their general aspect is uninviting, and the whole range is bleak and unfertile. The summit level is about 1000 feet above the sea, and rises at one point, Criblaw, to 1615 feet. Along the base of these hills, and in the numerous hollows which run into them, a red soil prevails, overlying the old red sandstone, which in general is fertile and admits of profitable cultivation. The higher grounds are fit only for sheep-walks, and are with slight exceptions entirely devoted to that purpose. It is strange, however, to notice how large a portion of these elevated grounds has at some remote period been subjected to the plough. Some of these furrows obviously bear date from the close of the eighteenth and beginning of the present century, when the exorbitant price of grain tempted many of the hill farmers to cultivate an increased breadth of their lands. But these comparatively modern ploughings can at once be recognised by the straightness and uniform width of the ridges, whereas the really ancient ones are invariably serpentine and irregular. The present occupiers of these hills are in general fully alive to their unfitness for arable husbandry, and accordingly confine themselves to pastoral pursuits. These elevated grounds have been much improved for this purpose by judiciously disposed fir plantations, and other artificial means of shelter from the snow storms to which the district is much exposed, and still more by a wholesale system of surface draining. By these simple and inexpensive means, the health and well-doing of the flocks has been very greatly enhanced. These consist of Cheviot and blackfaced sheep; both of which mountain breeds are here cultivated with eminent success.

To a spectator looking from the summit of any of the front-lying eminences of the Lammermuirs, the whole of the lower valley of the Tweed, with the Merse in the foreground, is seen spreading out in an apparently unbroken plain, from the base of the hill on which he stands to that of the opposite Cheviot range. And hardly anywhere can a lovelier landscape of the kind be met with, presenting as it does a wide expanse of richly wooded and highly cultivated country, surrounded by a natural barrier of picturesque hills which inclose it on all sides, except at the narrow opening through which the Tweed empties itself into the German Ocean. This apparently level plain has in reality a very undulating surface; the whole valley being traversed lengthwise by a succession of parallel wave-like ridges. It has this peculiarity in addition, that the land has a considerable slope from the coast inwards. An obvious proof of this latter fact is presented by the rivers Till on the Northumberland side, and Leet in Berwickshire, which fall into the Tweed near Coldstream after a course from the coast inland. The traveller finds also that the roads which traverse the Merse from east to west are comparatively level, whereas on those which run from south to north he is harassed by a perpetual rise and fall. The streams which drain the district flow through these hollows, for the most part in deep and narrow ravines, where they make little show in the general landscape, although rich in secluded nooks of exquisite beauty. The ancient marshiness of the district was not therefore owing to its flatness, but to the prevalence of land-locked hollows in which water stagnated. That very undulation of surface which occasioned its swampiness has in fact afforded peculiar facilities for its artificial drainage. This has been so effectually accomplished, that the county is now as remarkable for the absence of water as it once was for its presence. The salubrity of the district, as well as its fertility, has been greatly enhanced by this wholesale drainage. Ague, once the scourge of its inhabitants, has absolutely disappeared; and its flocks are now exempt from the rot.

Berwickshire

Berwickshire is strictly an agricultural county, as—with the exception of its fisheries, a gingham factory (at Earlston), some small woollen mills, and two considerable paper mills—there are no branches of industry pursued but such as are either directly connected with or subservient to the culture of the soil. Its agriculture, however, is of the first order. For this it is chiefly indebted to natural advantages of soil and climate, but in no small degree also to its proximity to England. To the latter circumstance it owes the early introduction of improved varieties of grain and other crops, of improved modes of cultivation, of valuable breeds of live stock, and of good markets in which to dispose of its produce. In common with the neighbouring county of Roxburgh, it bears a striking resemblance in the style of its agriculture to several of the midland counties of England. The most marked features in its husbandry are the great extent and excellence of the turnip crops, and of the flocks and herds by which they are consumed. Until a comparatively recent date the cattle and sheep reared in this county were, after being brought to a fair state of flesh, transferred to England, where the fattening process was completed; but now, owing to the increased cultivation of turnips, the tide has completely turned, and immense herds of growing cattle are annually brought from the northern counties of England into the valley of the Tweed, where they are fully fattened and then returned to the butcher markets of the south. This great increase in the extent and weight per acre of the turnip crops is due in part to tile-draining, but still more so to the liberal use of extraneous manures, such as guano and bones. These improvements in the cultivation of the arable parts of the county have led to corresponding ones in the pastoral district. Formerly the sheep farmers brought their stock to market as full-grown wedders; but now their grounds are stocked almost entirely with ewes, the lambs from which are sold at weaning-time to the low-country farmers, and by them are sent to the butcher markets when from sixteen to twenty-four months old. The most of these lambs are a cross breed between Cheviot or blackfaced ewes and Leicester rams. These yield a larger price to the breeders than they could obtain from the pure mountain stock, while the increased size and propensity to fatten which they derive from the mixture of Leicester blood, adapts them to the purposes of their low-country purchasers.

The agriculture of the county has recently derived considerable advantages from the railways by which it is now intersected and skirted. This at once led to the establishment of a weekly grain market at Dunse, in the centre of

Berwick-shire.

the county, and of a fortnightly cattle market at Berwick-on-Tweed. Nearly the whole produce of the county is now sent to market by this rapid and economical mode of conveyance. The facilities which it affords for obtaining draining and building materials, lime, extraneous manures, and fuel, have greatly furthered the agricultural improvement of the whole county, but especially of its more inland parts.

The arable farms usually contain from 300 to 500 acres, lying compactly together, and divided by well-kept thorn hedges into fields of from 20 to 40 acres each. Each farm has its substantial homestead, placed as near its centre as possible. They invariably possess thrashing machinery, which, when water is not available, is propelled by a steam-engine. Another feature of these homesteads is that they always comprise as many cottages as are required to accommodate the whole of the labourers statedly employed on the farm, which is at the rate of about one family for every 50 acres of arable land. Until a very recent period, these cottages were for the most part of the very rudest construction —mere hovels, in fact, with low unplastered walls, earthen floors, a single small window, the interior open to the rafters, and unpartitioned except by the box-beds of the occupants. A thorough reformation has, however, been in rapid progress during the past ten years. These cottages are now made higher in the walls, have good slated roofs, brick floors, partitions dividing them into two or more apartments below, and a deal floor and chambers above. The windows are large and made to open, and conveniences conducing to cleanliness and external neatness are usually provided. The establishment on a 400 acre farm of good land usually consists of a steward, a shepherd, five ploughmen, a man of all work, and perhaps a female cottar. These labourers are engaged for a year from Whitsunday to Whitsunday, and are paid for the most part in stipulated quantities of farm produce. The wages of an ordinary ploughman, or *hind*, as he is here called, consists of the following items: 54 bushels of oats, 21 do. of barley, 9 do. of peas, the keep of a cow (viz., grass in summer, turnips and straw in winter), L.4 in money, food for himself and wife in harvest, and some gratuities when sent to market with grain. This constitutes the hind's own wages; but, as he engages to provide at all seasons a young woman or lad for the lighter work of the farm, he receives at the rate of 10d. a-day for the actual time that this young person is employed; and to compensate him for her board, he gets one-third of an imperial acre of land on which to plant potatoes. The farmer furnishes manure and horse-labour for this crop, and the hind supplies the sets and undertakes the hoeing and digging. The farmer also provides a cottage and small garden for each hind, and the cartage of what fuel he requires; for which the latter pays rent by giving the labour of a female reaper (usually his wife or daughter) to assist in cutting down the crop of the farm. The money value of a hind's wages varies, of course, with the price of grain; but it usually keeps very near the rate currently paid in the district to day-labourers employed at job-work. The hind has this important advantage, however, that, being engaged for the year, his pay is not interrupted by occasional sickness or by bad weather. Farm-stewards and shepherds receive the same quantities of grain, &c., as the ploughmen; but the money wages of the former are greater by from L.6 to L.8, and the latter have the grazing of from eight to twelve sheep in lieu of the money wage. This had, indeed, formerly been the case with the ploughmen also, as they still speak of the money part of their wages as their "*sheep siller*." This hind system has undoubtedly wrought well for all concerned. The payments in produce guard the labourer from the injurious effects of excessive fluctuations in prices; they tend to encourage habits of thriftiness and sobriety; and the possession of a cow, a pig, and plenishing for a cottage, constitutes the hind a little capitalist, and furnishes at once a motive and guarantee for his good behaviour. The farmer and his labourers, from living together as a distinct community, take an interest in each other's family affairs, and interchange a variety of good offices which exercise a most wholesome influence on all. The plan of engaging *families* rather than individuals, and giving them a cottage on the farm, has the effect of preserving intact that blessed relationship, and of retaining the young under its hallowing influences to a later period than would otherwise obtain. The most plausible objection urged against the system has reference to that feature in it that the hind is taken bound to keep a young person (hence called a *bondager*) for the lighter work of the farm. When a hind has no grown children of his own it is said to be a hardship to him to have to hire in a stranger for this purpose, and that the young person so hired suffers by removal from under parental superintendence, and by being usually necessitated to sleep in the same apartment with the hind and his wife. It must, however, be remembered that these young persons are just the children of other hinds, and that they live in all respects as they would do in their parents' houses, and are usually treated as if they were members of the family. What is an inconvenience to individuals thus becomes a benefit to the class, and the manner in which they are too often lodged is an argument rather for improving the cottages than for interfering with the system. The admirable conduct, intelligence, and general good condition of the peasantry of this county affords the best possible proof that the hind system is a wise and beneficial one.

Berwick-shire.

The rivers of the county are, the Tweed, which skirts it for about 27 miles, and falls into the sea at Berwick; the Whitadder and the Blackadder, both taking their rise in different parts of the Lammermuir hills, and after uniting falling into the Tweed; the Eye, running into the sea at Eyemouth; the Leader, which gives its name to Lauderdale; of smaller note, the Dye, the Leet, and (for a short part of its course, before it enters Roxburghshire) the Eden. The most of these rivers flow with a rapid current, and so afford an abundant water-power, which is extensively employed in propelling corn and other mills. The value of this power has, however, been seriously impaired by the recent extensive drainage of the district. The rapidity with which rain-water is now discharged gives rise on the one hand to floods of unwonted vehemence, and, on the other, to such a diminished stream in fair weather, that scarcely a season now occurs in which many mills are not occasionally idle for lack of water.

The salmon-fishery of the river Tweed is very valuable, and has been the subject of many royal grants. For a number of years past a steady decrease has occurred in the quantity of these fish sent to market. This is due, perhaps, in some measure to the contamination of the waters by the influx of refuse from an ever-increasing number of woollen, paper, and other mills on the higher streams, but chiefly to an excessive capture of the fish by the proprietors, and to the enormous destruction of breeding fish by poachers during the annual close-time. Several attempts are at present in progress for multiplying these fish by the use of artificial spawning beds and rearing ponds. It is a curious fact, that during the past thirty years the sea or bull trout has increased greatly in numbers in the Tweed, as compared with the salmon proper, and has even taken possession of some of its tributaries, to the entire exclusion of the more valuable species. A similar and contemporaneous phenomenon in the natural history of the county has occurred in the Lammermuirs, where the common brown grouse have to a considerable extent been supplanted by the black game.

The sea-fishings at Eyemouth, Burnmouth, and Coldingham, are now of great and rapidly-increasing value. For a long time the inhabitants of these villages were much demoralized by being constantly engaged in a contraband trade in foreign spirits. The establishment of an efficient coast-

Berwick-shire.

guard entirely suppressed this pernicious traffic, and compelled the fishermen to apply themselves steadily to their legitimate calling. They are now an exceedingly industrious and prosperous class of people. No branch of industry in the county has benefited so much as theirs has done by the introduction of railways. Formerly they sold their fish, either to hawkers, who disposed of them in the neighbouring district; or to curers, who, by a process of salting and drying, prepared them for more distant markets. Now a large proportion of the fish is bought up by the agents of fishmongers in the great towns of England, to whom they are despatched by railway as soon as they are brought to shore.

Although Berwickshire has benefited in many ways by its proximity to England, there are other respects in which its Border position exposes its inhabitants to serious evils. The higher duty levied on Scotch whisky on its passage into England tends to encourage smuggling. The vigilance of the excise-officers, however, is such as to render this traffic extremely hazardous to those who engage in it: it is now almost totally discontinued. Another and more serious evil has grown out of a difference in the marriage law of the two countries. In Scotland a simple declaration, before witnesses, by the parties, that they are husband and wife, constitutes a valid marriage. Out of this has arisen the practice of couples from England crossing the Border, and being married by unauthorized persons who make this their trade. To impart something of formality to their proceedings, these men are in the habit (often when in liquor) of profanely making use of a form of prayer borrowed from the liturgy of the Church of England, and of filling up, with dates to suit the parties, a printed certificate of marriage, of which they have blank copies in readiness. Gretna Green has long possessed an unenviable notoriety for such proceedings; but the same irregular practice goes on at all the toll-bars and similar places situated on the borders betwixt Berwickshire and Northumberland. Nor is it confined to parties from England; for a very large proportion of the marriages among the working classes in Berwickshire take place at these tolls. The facilities thus presented for taking the most important step in life in a clandestine manner, necessarily tend to foster innumerable evils.

The county is not rich in the more valuable minerals. Thin seams of coal are known to exist in the S.E. corner of it. On the sea-coast at Lamberton several attempts have recently been made to work these, but hitherto without success. Beds of clay suitable for the manufacture of bricks and draining tiles are scattered over the county, and are in numerous instances used for this purpose. Good building materials are obtained from numerous quarries in the rocks, both of the old red sandstone formation, and of the coal measures. At Ordweel on the Whitadder, and some other places, copper ore has been found, and attempts made to work it, but hitherto without any encouraging success.

The antiquities of Berwickshire consist in the remains of military works, tumuli, and cairns; and in the ruins of many peel-houses and castles, the memorials of those incessant feuds and forays of which in the olden time this Border district was the scene. Until the beginning of the present century, there lingered among its inhabitants many traditionary reminiscences of the exciting events, fierce manners, and precarious tenure of life and property with which the Border clans were once so familiar. These popular traditions have disappeared with the progress of modern civilization, even more thoroughly than the physical memorials have done under the effects of time and agricultural improvement. Of the religious houses once so numerous, few now remain. Coldingham Priory, the most famous of them, was burned by the Earl of Hertford in his barbarous inroad into Scotland in the year 1545. The abbey of Dryburgh shared the same fate by the same hands, but its ruins yet remain to delight the eye of the traveller. The deep glen of the Pease Burn, in the N.E. angle of the county, is notable in history as one of the natural defences of Scotland. The bridge of four arches by which it is spanned, used to be, from its great height and romantic situation, an object of some curiosity; but the stupendous railway works, with which the public eye is now familiar, have quite eclipsed the honours of such objects as the Pease Bridge.

North Berwick || Berwick on-Tweed

Among the principal family seats in Berwickshire are the following: Thirlstane Castle (Earl of Lauderdale); the Hirsel (Earl of Home); Lennel House (Earl of Haddington); Dryburgh Abbey (Earl of Buchan); the Retreat (Earl of Wemyss); Mertoun House (Lord Polwarth); Nisbet (Lord Sinclair); Dunse Castle (Hay); Bemerside (Haig); Jerviswood (Baillie); Wedderburn (Home).

Berwickshire is divided into thirty-two parishes. The population, which in 1801 was 30,621, had increased in 1841 to 34,345, and in 1851 to 36,287. The parliamentary constituency in 1850 was 1062. It returns one member to parliament.

Its towns and villages are few and inconsiderable. Berwick, from which the county takes its name, forms no part of it, but yet is virtually its chief market-town. The other towns are Dunse, Lauder, Eyemouth, Coldstream, and Greenlaw. The latter is the county town, but from its inconvenient position, the sheriff-court business has, by a recent act of parliament, been transferred to Dunse. The valued rent of Berwickshire is L.178,366 Scots. The annual value of real property, as assessed in 1815, was L.245,379, and in 1842, L.252,945. In 1849 the number of enrolled paupers was 1315, and the assessment for relief of the poor L.9403, 9s. 11d. (J. W—N.)

BERWICK, *North*, a parliamentary burgh and parish of Scotland, county of Haddington, situated on the coast of the Firth of Forth, with a small harbour, but little or no trade. The town was constituted a royal burgh by James VI. Pop. of parish (1851) 1643, of whom 498 resided in the town. Distance from Haddington 9 miles, east from Edinburgh, by railway, 22¾ miles. It unites with Haddington, Dunbar, Jedburgh, and Lauder, in sending a member to parliament. It is governed by a chief magistrate, two bailies, and twelve councillors. The people are chiefly engaged in agriculture. Fishing and quarrying afford employment to a limited number. The town consists of one principal street, and contains a parish church, Free church, and a United Presbyterian place of worship. North Berwick is frequented in the bathing season. The surrounding scenery is interesting. About 2½ miles to the east of the town stand the ruins of Tantallon Castle, so graphically described in *Marmion*. The parish of North Berwick contains about 4000 acres, mostly arable. The geological formation is red sandstone and trap. North-Berwick Law, a conical hill, 940 feet high, stands close to the town.

BERWICK-ON-TWEED, a seaport town of England, situated at the mouth of the river Tweed, on its northern bank. Pop. (1851) 16,008. The townships of Tweedmouth and Spittal, on the opposite bank, are included in the borough of Berwick, and, with Berwick itself, are described in all law documents as "in the county of the borough and town of Berwick-upon-Tweed." By 2d and 3d Will. IV., cap. 64, sec. 29, it was appointed one of the polling stations for the county of Northumberland. It now constitutes an integral portion of that county, and is under English law. The borough and its liberties (commonly known as "Berwick Bounds,") forming one parish, occupy an area of nearly 8 square miles, and extend about 3½ miles northward along the coast, and about the same distance westward. The point on the north road at which they terminate is the village of Lamberton (in Berwickshire), a place of some celebrity as another Gretna Green. A toll-house adjoining the village of Paxton marks the western boundary; and to this place a similar interest attaches. By 7th and

Berwick-on-Tweed.

8th Vict., cap. 61, that small detached portion of the county palatine of Durham called Islandshire, which lay on the south side of the river, reaching to the centre of the stream, was, on account of the inconvenience resulting from the old division, included in the district of Berwick.

The town is encircled by fortified walls, bastions, and a ditch, constructed during the reign of Queen Elizabeth. These ramparts, which are under the custody of the corporation, form a delightful promenade, and might, if required, be put into a state of defence. Of the five old gates, namely, the Scotch gate, the Cow-port, the Shore-gate, the Pier-gate, and the English gate, the last has been removed. About half a mile to the north of the existing walls, the remains of the ancient fortifications are to be seen, including the Bell Tower, and a portion of Lord Soulis' Tower. The castle was situated at the W.N.W. extremity of these walls, and a portion of it still remains, including the barbican (in good preservation), which faces the west, and extends to the margin of the Tweed. The old courtyard of the castle is now occupied by the station of the North British railway. A viaduct of 28 arches, 2000 feet in length, and 120 in height, crosses the Tweed here, forming a striking feature in the landscape. This bridge was opened by Queen Victoria in person in 1850. The old bridge of Berwick, which stands about a quarter of a mile farther down the river, has 15 arches: it was completed in 1634. The internal appearance of the town is pleasing, and when viewed from the high ground on the south side of the river is exceedingly striking. It has scarcely any suburbs outside the fortifications, the river and the sea inclosing it on the south and east. The entrances to the town are on the W.N.W. by the Scotch gate leading into the High Street, and on the S. by the old bridge. Among the principal public buildings is the town-hall, a massive three-storied structure, with a portico supported by four Tuscan columns, and surmounted by a spire of 150 feet, with a chime of eight bells. The ground floor contains the exchange, which is used as a market-place for dairy produce. In the second story the quarter-sessions, county-court, and corporation meetings are held. The upper story, formerly used as a jail, is occupied by the superintendent of police. The new jail, opened in 1849, stands on the east side of Wallace's Green. The church of the Holy Trinity, at the N.E. angle of the town, was rebuilt in 1648. Like other structures of the Puritan period, it has no pretension to architectural elegance. The benefice is a vicarage in the patronage of the dean and chapter of Durham. The annual value of the tithes is L.2300. There are two places of worship in connection with the Established Church of Scotland; four United Presbyterian, and Independent, Baptist, Methodist, and Roman Catholic chapels. At Tweedmouth there is a curacy, a Scotch Established, and a Free church. The barracks stand opposite the church, and between them and the churchyard wall is the military parade.

The educational institutions are the following:—The corporation's academy for the gratuitous education of burgesses' children, averaging 300 pupils; the grammar-school, which is also free to the children of burgesses; a charity school; a Lancasterian school; a school of industry for girls; an infant school, &c. &c. Berwick possesses a public subscription library (6000 volumes), a reading-room, a mechanics' institute, a natural history society, a dispensary, a workhouse, and assembly rooms. There are two banks, branches of the Northumberland and Durham, and of the Union Bank; and also a savings-bank. Two weekly newspapers are published here, the *Berwick Warder* and *Berwick Advertiser*.

Berwick, since the time of Henry VIII., has returned two members to parliament. Constituency 676, 380 of whom are burgesses. The burgh, including Tweedmouth and Spittal, is governed by a mayor, six aldermen, and seventeen councillors, a recorder, sheriff, &c. The only article of manufacture is iron: there are several foundries and boiler manufactories at Tweedmouth and Spittal. The chief exports are corn, wool, game, and salmon. Most of the fisheries between the sea and Norham belong to, or are rented by, the Berwick Shipping Company. The average number of boxes of red fish exported during the season (15th Feb. to 15th Oct.) is 4000. Most of the fish goes to the London market. The entrance to the harbour is rocky, and has a bar, within which there is good anchorage. It is protected by a pier, with a lighthouse and two fixed lights, in Lat. 55. 46. N. Long. 2. 0. W. Distance from London by railway, 369 miles, from Edinburgh 58, and from Newcastle 64. Corn-market every Saturday; cattle-market every alternate Monday. The fair is held on the last Friday of May; there are also four hiring-markets annually.

Beryl.

Of the early history of Berwick, the Scottish chartularies supply the only records. It belonged to Scotland, as part of the Lothians, in the reign of Kenneth II.; and about 870 was in possession of the Danes, from whom it was wrested by Gregory. It thereafter remained in the custody of Scotland until towards the close of the eleventh century, when Edgar in pious gratitude bestowed it on the see of Durham; but again resuming it, it became a portion of the appanage of David; after whose accession in 1124 it was constituted one of the four royal burghs, and was long the chief seaport of Scotland. On the threshold of the two kingdoms, it suffered greatly during their wars. It was acquired in 1174 by Henry II., and for a pecuniary consideration was restored to the Scots by Richard Cœur de Lion in 1189. During the reign of Alexander III. the customs of the port amounted to L.2197, 8s.—about one-fourth that of all England. In 1292 Edward I. sat in Berwick Castle as umpire of the disputed claim to the crown of Scotland, declaring in favour of John Baliol. In 1296, having obtained a victory over the Scots and captured Berwick, Edward I. held a parliament there to arrange the future government of Scotland, and to receive homage. The heroic defence of the Red Hall—a strong building in the town—by thirty Flemish merchants who had received it from Alexander II. on condition of their never yielding it to the English, forms a well-known feature in the history of this siege. In 1297, Wallace—who had routed the English near Stirling—made his way into Berwick; but the castle having held out until succoured by Edward, the Scots were forced to retire. It was retaken by Bruce in 1318. Subsequently changing masters several times, it was, in 1551, made independent of both countries. In 1648 it was taken and garrisoned by Cromwell's forces. The lands held by the burgesses, and other privileges, are by charter of King James VI. (See Tytler's *History of Scotland*, and Redpath's *Border History*.)

BERYL; *aqua-marine; émeraude limpide; beril.* This mineral, as was originally conjectured by Pliny, is a variety of the emerald, being distinguished from the latter only by its colour. The term emerald is consequently confined to that variety which presents its own peculiar colour, namely, the rich deep emerald green; while that of beryl is given to all the other varieties, as the sea-green, pale-blue, golden-yellow, and colourless.

Of the emerald we shall treat under the proper head; for although it is identically the same mineral, it sometimes leads to confusion to treat beryl and emerald under the same denomination. For instance, Haüy, speaking of emerald in the first edition of his *Traité*, says that the largest crystal he ever saw measured six inches in length and two in thickness, and that it came from Peru. In his second edition he mentions, as the largest he had ever met with, a crystal of the same dimensions which came from Santa Fé; and immediately passes on to a description of the *Siberian* emeralds. He considered them as the same mineral species. The large crystal which he mentions is in the royal collection at Madrid, and is the true emerald. This points out the propriety of confining the name of emerald to the beautiful deep green

Berzeline || Berzelius.

gem, while that of beryl may be bestowed on all the other varieties. These are by no means uncommon. They occur in veins and drusy cavities in granite, and are found in France, at Nantes, and at Limoges; in Ireland, in the mountains of Wicklow and the county of Down; in Scotland, in the district of Cairngorm; at Schlaggenwald in Bohemia; at Swezel in Bavaria; at Brodbo in Sweden; and in the Altai and Oural Mountains in Siberia, where they seem to exist in greater abundance and in larger groups and crystals than in any other quarter of the world, always excepting the varieties from Limoges. In Peru and Brazil, there are localities well known as producing beryls. In the northern states of America many of these have been indicated by the American mineralogists. Some very fine pale green-coloured beryls have been imported from the district of Ghellan, in Hindustan, 300 miles S.W. of Madras. This mineral, therefore, is not unsparingly distributed over the globe; and it affords one of the greatest embellishments to the cabinet of the mineralogist, while it yields an abundant supply to the jeweller for the exercise of his taste in producing a variety of ornaments.

Although Pliny was the first who suggested the identity of the emerald and the beryl, it was left to Romé de Lisle to put this conjecture to the proof. Pallas, who first discovered the beryl in Siberia, sent some specimens for examination to that crystallographer, who immediately observed the perfect similarity of form between some of these and certain crystals of emerald then in his possession; which circumstance, joined to the hardness and specific gravity of the two objects, soon satisfied him that they were of the same species. This was one of the first triumphs of crystallography; and it was soon after confirmed by the labours of the chemist. The analysis of this mineral is peculiarly interesting, as will be seen by the following comparative table:—

	Emerald.		Beryl.				
	Vauquelin, Peru.	Klaproth.		Vauquelin, Siberia.	Klaproth, Nertschinsk.	Berzelius, Brodbo.	Schirab, Siberia blue.

The largest mass of precious beryl known to mineralogists is an aqua-marine belonging to the late Don Pedro: it is nearly as large as the head of a calf, and weighs 225 ounces Troy, or 18 lb. 9 oz. On one side there are slight indications of the plane of a crystal; but it is otherwise entirely water-worn. Its surface is consequently dull; but beneath it the mass is perfectly clear and transparent, and, large as it is, without a flaw. It presents a beautiful pale bottle-green colour. The largest crystals known are those from Limoges in France, and Brodbo in Sweden. At the former place they occur in a vein of quartz in granite, sometimes very perfect, and a foot in diameter; and there is a crystal from the latter place in the museum of Stockholm which weighs upwards of eighty pounds. These large crystalline masses are generally very coarse in their texture, and present an earthy aspect, somewhat like decomposed felspar.

BERZELINE, a mineral found in minute dendritic crusts on calc-spar. It is a seleniuret of copper. It occurs in Sweden and the Hartz.

BERZELITE, a honey-yellow mineral of a resinous lustre, found in Sweden. It is an anhydrous arseniate of lime and magnesia.

BERZELIUS, Baron Jan Jacob, knight commander of the Swedish order of Vasa, member of the French Legion of Honour, and of the Austrian order of Leopold, M.D., &c., &c. The honourable titles here enumerated can scarcely be said to add lustre to the name of this distinguished philosopher, but are creditable to the sovereigns and bodies who testified in this manner their appreciation of labours inseparably connected with the progress of physical science in the present century. Berzelius.

Berzelius was born August 29th 1779, at the village of Vasefunda, near Linkoping in Ostrogothland, where his father filled the humble, but in Sweden not unappreciated, office of government schoolmaster. His early acquirements and useful habits of study were formed under the care of an intelligent father. In 1796 he commenced his medical studies in the University of Upsala, where the chemical chair was then filled by Afzelius, with Ekeberg for his assistant. The account which Berzelius gave of the mode of teaching chemistry in that celebrated seminary shows how little he owed to his instructors; and contrasts very unfavourably with the practice then long established in the chemical schools of this country, when Cullen and Black had for about half a century illustrated their prelections by numerous and well-devised experiments. Berzelius stated that at Upsala the lectures were read without any experimental illustrations, and the instruction in the laboratory was of the most meagre and unsatisfactory kind.

In 1798 Berzelius quitted the university, after passing his examinations in philosophy, and became assistant to a medical practitioner at Medvi, where he soon made himself known by a masterly chemical analysis of the mineral waters of that place, which was, however, not published until he took his degree of physician, in 1804, at Upsala, where it appeared under the joint names of Berzelius and Ekeberg. Soon afterwards he gave to the world his *Physical Researches on the Effect of Galvanism on Organized Bodies;* a work which established his reputation as an experimental philosopher. He was now appointed the assistant and successor of Sparman as professor of medicine, botany, and chemical pharmacy; and succeeded to that chair in 1807. Berzelius at first followed the mode of teaching which he had seen at Upsala; but it appears that, on the suggestion of the late Dr Marcet, who at that time visited Stockholm, he adopted the method of illustrating his lectures by experiments, and speedily found that this change gave great satisfaction to his pupils, and made him a most popular teacher of chemical science.

It was in 1806 that, in conjunction with Hissurger, he commenced the *Memoirs relative to Physics, Chemistry, and Mineralogy*, his numerous contributions to these sciences exhibit that marvellous ingenuity, perseverance, and accuracy in analysis, which have placed his name among the most illustrious experimental philosophers of the age. Berzelius may also be considered as the principal founder of the highly important "Medical Society of Sweden." In 1808 he became a member of the Royal Swedish Academy, and was chosen its president in 1810.

In the intervals of his public duties he paid several visits to Paris; and in 1812 was some time in London, of which visit he always spoke with much satisfaction.

In tracing his personal career, we may briefly state that in 1815 the sovereign of Sweden enrolled his name among the knights of the *Order of Vasa;* and in 1818 he was declared perpetual secretary of the Stockholm Academy of Sciences. In the same year, on the coronation of King Charles-John, he was ennobled; and, as a special mark of distinction, was permitted, contrary to the custom of Sweden, to retain his own name; and the title of Baron Berzelius dignified the lists of Swedish nobility. In 1821 his sovereign made him "Commander of the Order of Vasa;" and foreign princes imitated the example, by nominating Berzelius a member of "the Legion of Honour" of France, and a chevalier of "the Order of Leopold" of Austria.

Berzelius.

During all that time his very important experimental researches were never intermitted; and he devoted his vigorous mind, and uninterrupted bodily health, to the cause of science with untiring ardour. When he resigned his professorship in 1832 in favour of Mosander, he continued most ardently to pursue his refined investigations.

In 1833 Berzelius took a wife; and on that event the king of Sweden wrote him a letter, in which, among other laudatory remarks, he observed, that "Sweden and the whole world were debtors to the man whose entire life had been devoted to pursuits as useful to all as they were glorious to his native country." He also about the same time received a gratifying and valuable testimony to his important services to the arts of his country from the directors of the Swedish iron works, who, in grateful acknowledgment of the light his researches had thrown on their art, conferred on him a pension for life. Among the honours conferred on him we may likewise mention, that, at a dinner given by the Academy of Sciences, of which he had been secretary for twenty-five years, the health of Berzelius was proposed by the crown prince, the chairman, who in the most complimentary terms expressed his own personal gratitude to him as the scientific instructor of his youth.

The admiration of Europe and the gratitude of his country attended him to the latest period of his life. In the midst of his fame and of his unwearied labours, Berzelius was attacked with paraplegia. He saw with calm resignation his mortal career closing, and strove to complete those investigations which he had commenced while his powers were yet equal to the task. His decay was gradual, without acute suffering; and he died on the 1st of August 1848, in the sixty-ninth year of his age.

The writer of this article considers it as one of the most fortunate events of his life that he had the pleasure of a personal acquaintance with this illustrious philosopher, and bears a willing testimony to the noble frankness and manly simplicity of his character. Berzelius was ever ready to impart, without ostentation, to others his vast stores of knowledge, —to assist the researches of those engaged in kindred pursuits, by his advice, by the unreserved communication of his beautiful methods of accurate investigation, the use of his laboratory, and by a kindness of manner that irresistibly won the attachment of all who approached him. His well-earned reputation elevated him above all jealousy of others; and, as has been well observed in the *Eloge* of Louyet in the Academy of Brussels, "Berzelius was jealous only for the cause of chemistry." Hence the occasional freedom of his strictures in his *Comptes Rendus Annuels*, which occasionally excited the displeasure of authors whose inaccuracies he detected or whose hypothetical views he opposed. But a man more willing to give due praise to the useful labours of others, or more free from a shadow of envy of contemporary genius, the author of this notice never yet had opportunity of knowing.

To attempt a detailed notice of his investigations and discoveries would be to review nearly the entire field of chemical science, for there are few parts of it which he has not illustrated; and we can here only notice his principal labours.

1. The volumes of the *Physical Memoirs*, during twelve years, containing forty-seven original papers by him of great importance.

2. His treatise on Chemistry, written with great clearness and precision, went through five large editions, and was on each occasion almost wholly rewritten. It will remain a monument of his industry and skill; for the researches there detailed are not copied from the writings of others, but are all either repeated or devised by himself. It is best known in the edition in eight volumes, translated into French, under his own inspection, by Eslangeo, and published at Bruxelles in 1835. The last volume contains an excellent dissertation on chemical apparatus, with essays on qualitative and quantitative analyses, and the use of the blow-pipe.

Besançon.

3. In 1822, at the request of the Academy of Sciences, he undertook those admirable *Annual Reports on the Progress of Physics, Chemistry, and Mineralogy*, which have proved of the utmost value to the scientific world; and the want of his free but candid and judicious criticisms is felt by all engaged in such researches.

4. His mineralogical system bears the impress of his penetrating mind. Convinced that an arrangement founded on the chemical constituents of inorganic matter was the most useful and the most interesting, he considered mineral species as depending on the atomic proportions of their principal ingredients. He arranged and designated individual minerals from this circumstance, regarding the ingredients not in atomic proportions as mechanical mixtures, that might vary in their proportions without materially changing the mineral.

5. In 1807, while the beautiful atomic theory of Dalton was scarcely well known in Britain, Berzelius began his accurate researches on "Definite Proportions;" in which, extending and systematizing the experiments of Wenzel and Richter, he applied them not only to salts, earths, and metals, but to gases and to organic compounds, and thus may be said to have been most instrumental in establishing the truth of the theory of definite proportions,—for the discoverer of which he ever expressed the profoundest respect. His determination of the atomic weights of various substances has obtained the highest praise; and, among other discoveries, we owe to him the proof of the remarkable fact, that the proportion of oxygen is constant in all the neutral salts of the same acid. It was his researches that gave the first impulse to modern organic chemistry, which of late years has made remarkable progress. We also owe to him a greater number of accurate analyses than to any other chemist of our day.

6. The last work of this celebrated man which we shall mention is his *Essay on the Use of the Blow-pipe*,—the most complete account of that instrument, of which he well knew the value. It has been translated into French by Fresnel, and from that language into English by Children in 1823. (T. S. T.)

BESANÇON, a city of France, capital of the department of Doubs, 45 miles east of Dijon, on the river Doubs, which flows round it on three sides. It is well protected by strong fortifications and a citadel on an almost impregnable rock. The town is in general well built; but the houses are old, and the streets narrow and gloomy. The principal buildings are, a Gothic cathedral, court-house, town-hall, royal college, arsenal, hospital with 500 beds, barracks, theatre, library of 50,000 volumes, museum, and several handsome fountains. It contains many Roman antiquities, including a triumphal arch, and the remains of an aqueduct and an amphitheatre. Besançon is the see of an archbishop, has tribunals of primary jurisdiction and commerce, and is the head court for the departments of Doubs, Jura, and Haute Saone. It possesses also a university-academy, a diocesan seminary, a royal academy of science and belle-lettres, a lyceum, an antiquarian museum, a society of agriculture and arts, and schools of medicine, artillery, and design, besides two deaf and dumb institutions. The chief branch of industry is the manufacture of watches and jewellery. There are also some considerable breweries, and manufactories of carpets, porcelain, hardware, Seltzer-water, &c. Besançon enjoys a central position for the commerce between France and Switzerland. Pop. (1851) 33,788. Long. 5. 56. 26. E. Lat. 47. 14. 12. N.

Besançon is a place of great antiquity. Under the name of *Vesentio*, it was held by the Romans as a fortified place in the time of Cæsar. It was destroyed by Attila, and since that period has suffered many vicissitudes. Area of the arrondissement of this name, 539 square miles; pop. 109,136.

Besant || Betchuana.

BESANT, or BEZANT, a coin of pure gold, struck at Byzantium in the time of the Christian emperors; and hence the gold offered by the king at the altar is called *besant* or *bisant*. It seems to have been current in England from the tenth century till the time of Edward III. Its value is not precisely ascertained, but it is generally estimated at 9s. 4½d. sterling.

BESOZZI, or BEZOZZI, AMBROGIO, an architectural painter of some eminence, born at Milan in 1648. He worked for a time under Dunedi, called Montalti; and afterwards studied at Rome. He died at Milan in 1706.

BESSARABIA, the most S.W. province of Russia in Europe. See RUSSIA.

BESSARION, JOHN, titular patriarch of Constantinople, archbishop of Nice, and one of those illustrious persons who contributed to the revival of letters in the fifteenth century, was born at Trebizond in 1389, or, according to Bandini, in 1395. He was very zealous to reunite the Greek with the Latin church, and induced the Emperor John Palæologus to interest himself in bringing about this great work. He passed into Italy, appeared at the council of Florence, harangued the fathers, and made himself admired as well by his modesty as by his uncommon abilities. The Greek schismatics conceived so great an aversion for him, that he was obliged to remain in Italy, where Pope Eugenius IV. honoured him with the purple in 1439. He fixed his abode at Rome, and would have been raised to the papal chair if Cardinal Alain had not represented it as injurious to the Latin church to choose a Greek, however illustrious. He was employed in several embassies; but that to France proved fatal to him. When legate at this court, he happened to visit the Duke of Burgundy before he saw Louis XI., which so displeased the capricious and tyrannical monarch, that he gave the cardinal a very ungracious reception, and even took him by his magnificent beard, saying, in his Latin patois, *Barbara Græca genus retinent quod habere solebant;* an affront which so chagrined the cardinal, as, according to Matthieu, to occasion his death at Ravenna upon his return, in 1472. Bessarion loved literary men and protected them. Argyropylus, Theodorus Gaza, Poggio, Laurentius Valla, and others, formed in his house a kind of academy, and pursued their studies in some measure under his direction. He left some works, as *Defensio Doctrinæ Platonicæ*, translations of some pieces of Aristotle, orations, epistles, &c.; and he bequeathed his valuable collection of books to the Venetian senate. He laid the foundation of the celebrated library of St Mark.

BESSEL, FRIEDRICH WILHELM, a distinguished Prussian astronomer, was born at Minden in 1784, and died March 17. 1846. For an account of his valuable contributions to science, the reader is referred to the article ASTRONOMY.

BESSI, an ancient people of Thrace, who dwelt along the southern slope of Mount Hæmus. They were a fierce and powerful race, and were probably never subdued till conquered by the Romans, after the subjection of Macedonia. Their chief town was Uscadama.

BESTAIL, or BESTIAL, in ancient statutes, all kinds of beasts or cattle.

BESTIARII (*θηριομάχοι*), those who fought with wild beasts in the Roman circus, or who were exposed to them by a sentence of the law. The bestiarii multiplied greatly under the empire, were regularly trained, and fought for pay. They are always distinguished from the gladiators, who fought with each other.

BETCHUANA, a considerable negro nation, consisting of many tribes that inhabit Southern Africa, to the north of the Gariep, or great Orange river, from about 28. to 23. S. Lat. An extensive desert is the western boundary between them and the Hottentots on the western coast; and a chain of mountains running parallel to the eastern coast, at the distance of 70 or 80 miles, divides them from Kaffirland. They have been described by Burchell, and by Campbell and other missionaries. The Betchuana are dexterous workers in copper and iron, which they fabricate into ornaments, arms, and agricultural implements, as spades and hoes. Their capital is Litâkun or Lattakoo. Each tribe is under an hereditary chief. The most civilized are the Vankeets and Mointzee tribes. The latter cultivate millet, sugar-cane, and tobacco: they build with stone, are dexterous smiths, and know how to draw copper wire, and to twist it into various neat ornaments. Of all the tribes the chief riches are cattle, and they deal in ivory to a considerable extent. Their dress consists of a covering round the loins, and cloaks of skins very neatly sewed together. (Burchell's *Travels;* Campbell's *Journeys; Geographical Journal;* Cumming's *S. Africa.*)

Betel.

BETEL, a substance compounded of different ingredients, which is chewed in the East in the same way as tobacco is used in other parts of the world, but to a much greater extent. All individuals, without exception of age or sex, begin at an early age to accustom themselves to betel, and it gradually becomes an article of such necessity, that those acquainted with the usages of the Eastern nations affirm they would more readily dispense with their ordinary quantity of food than with betel. Europeans also, who have resided long in Ceylon or India, contract the same habit, and enjoy chewing of betel equally with the natives. Betel, or *pawn* as it is denominated in Bengal, consists of part of the fruit of the *areca* palm, wrapped in the leaves of a kind of pepper plant called *betel*, smeared with a little shell lime; whence its name betel-nut is derived. The areca palm is a tree growing to forty or fifty feet in height, with a straight round stem six or eight inches in diameter, covered with a smooth ash-coloured bark, marked with parallel rings. All the leaves, which are only six or seven in number, spring from the top, and are six feet in length, declining downwards from a stalk of considerable length. The fruit or nut is covered with a green shell or skin, thin, brittle, and of the consistence of paper; it is of an oval shape, about the size of a small egg, and resembles a nutmeg despoiled of its husk. When ripe, it appears in clusters of a reddish colour, forming a beautiful contrast with the vivid green of its leaves, and then falls off to sow itself in the ground. The betel plant is a species of vine, bearing a leaf somewhat resembling ivy. It is called *piper betel* by botanists, and is of the same genus as the *piper nigrum* of Linnæus. Its culture, which is carefully attended to, is managed in the same manner. Poles are planted in the earth, around which the betel twines itself, and as it runs up, the poles require to be heightened. It is a creeping plant, seeking support from stronger vegetables, but it is said not to be destructive of them, like some other plants of a similar nature. Particular regard is paid to the cultivation of areca and betel throughout the countries of which they are natives. Several years ago it was found, on enumeration, that the number of trees, probably meaning the areca only, in Prince of Wales's Island, amounted to 342,110. The lime used with the nut is called *chunam*, and is obtained from the calcination of shells, which produces the finest kind. But the fresh nut must be avoided; it then contains a white viscous matter, insipid to the taste, and occasioning delirium, like ebriety from wine, but losing this property when dried; and it is employed either boiled or raw. The latter undergoes no change; the former is cut in slices, boiled with a small quantity of *terra japonica*, and then dried. Betel is compounded, therefore, of these three substances, with some additions or variations, according to the customs of the place where consumed; such as cardamums, and coarse pounded tobacco, by persons of more depraved taste. The union of the three ingredients is supposed to correct the effects which each would produce singly; the nut improves the bitterness of the leaf, and the lime prevents any injury to the stomach. When combined, the first consequences are, reddening the saliva, giving a bright hue

Betel.

to the lips, and, in progress of time, rendering the teeth quite black. The saliva, however, will not be tinged if the chunam be omitted; and its pernicious operation on the enamel of the teeth may be averted by rubbing them with a preparation whereby they are coated with a black substance that does not readily yield to any dentifrice, and preserves them from corrosion. Its medicinal effects are the dispelling of nausea, exciting an appetite, and strengthening the stomach. It possesses nutritious and enlivening qualities, which render it particularly acceptable to its consumers. The *terra japonica*, above alluded to, is not a universal ingredient; it is used only in certain countries, and is generally supposed to be a preparation from the areca nut itself. It consists of two varieties, the one very astringent, the other less so, and rather sweet, which is preferred by the betel-eaters. To obtain the former, the nuts are taken from the tree, and boiled some hours in an iron vessel; they are then removed, and the water remaining is inspissated by continual boiling. The nuts being dried, undergo a second boiling, and, having been taken out, the water is also inspissated, whereby the best *terra japonica* is obtained. The nuts are then dried, cut in two equal parts, and sold. Or it is obtained by inspissated decoctions of the wood of the keira tree, or *mimosa catechu*. A great quantity of this substance is made in the Mysore, and some of inferior quality in Bengal. Probably it is something of this same kind that is prepared in Sumatra, under the name of *catacamber*, and chewed along with betel to give it an additional flavour.

Betel is not only used as an article of luxury, but as a kind of ceremonial which regulates the intercourse of the more polished classes of the East. When any person of consideration waits on another, after the first salutation, betel is presented as a token of politeness: to omit it on the one part would be considered neglect, and its rejection would be judged an affront on the other. No one of inferior rank addresses a dignified individual without the previous precaution of chewing betel; two people seldom meet without exchanging it; and it is always offered on the ceremonious interviews of public missionaries. In some countries it is not uncommon for the guest who receives the betel from his host, to pass it between his thumb and fore-finger, and apply his own chunam, which never gives offence, and is thought to have orginated in guarding a stranger against the insidious conveyance of poison, formerly too frequently practised in destroying persons who were obnoxious. Philtres or amatory charms are still conveyed along with the chunam, and are conceived to consist of some powerful stimulants. Mahometans abstain from this indulgence during the fast of Ramadan, though possibly not in every country, as it would be too great a privation; and the use of it is so interwoven with the existence of the natives of the warmer climates, that females of the higher ranks are said to pass their lives in doing little else than chewing betel. When the Cingalese retire to rest at night, they fill their mouths with it, and retain it there until they awake. According to Knox, who passed many years in captivity on the island of Ceylon, most people going abroad carry a small box of gold or silver, containing the ingredients for compounding betel; and the poor keep a constant supply about them in purses of coloured straw, securely lodged in a fold of their garments. The stand or box containing it is often of elegant workmanship; it consists of silver, gold, or tortoise-shell, and forms a piece of ornamental furniture in the houses of the wealthy. It is sufficiently valuable to constitute a present between sovereigns.

Extensive gardens for cultivating betel are formed in different parts of India. The soil most favourable for the palm is a black mould on a substratum of limestone, or intermixed with calcareous nodules. Here it is planted in rows, and carefully manured and watered during several years. It begins to bear from the eighth or tenth to the fifteenth year, and remains in perfection for thirty years, soon after which it either dies or is cut down. Some, however, continue producing fruit from the fiftieth to the seventieth, or even the hundredth year; but the produce gradually declines both in quantity and quality. It appears that a very fertile tree produces at an average 857 nuts, and an ordinary one 600; but this does not hold everywhere, as there are trees affording no more than 200. The betel-leaf is either cultivated in separate gardens, where a red stony soil on the side of a rising ground is preferred, and plantains or bamboos planted along with the vines, which are arranged in trenches to support them as they grow; or when an areca plantation is formed, and the palms are fifteen years old, cuttings of the vine are planted near the roots, and trained up to the trees. In twelve or eighteen months the leaves of the vine are fit for sale, and in three years they are full-sized; but in another year they die, when all must be removed, and young plants immediately substituted for them. We do not know whether their duration is ever longer; but in the southern parts of Canara in India, the gardens require renewal every four years, and in eighteen or twenty the soil is considered to be exhausted. These gardens are always surrounded by a hedge; sometimes the cultivators are annoyed with the depredations of squirrels and elephants. The crop of areca is produced during three months; and the nuts being pulled, are cut into seven or eight pieces each, and piled up in a heap; then equal quantities of it and *terra japonica*, with a hundred leaves of betel-leaf, are beat together with water, and the juice strained into a pot. This is mixed with a decoction of the bark of the *mimosa indica* and water, and the nuts from the whole heap are successively boiled in it. They are then exposed to be dried in the sun.

Betel is a very considerable article of traffic in India and China, and, indeed, throughout Asia. In the British settlements of Bombay, Madras, and Bengal, the value of the imports amounted in a single year to L.138,836; and if the quantities consumed throughout the East are taken into view, it will appear surprising how they can be obtained. But, owing to the constant and extensive demand, the plants affording the necessary ingredients are carefully cultivated; and multitudes are employed and subsisted in the production of this Eastern luxury. (J. G. D.)

Bethabara ‖ Bethesda.

BETHABARA, or BETHBARAH, *i. e. place of the ford*, where the Israelites passed over the Jordan, mentioned in John i. 28. The best manuscripts, however have Bethany: the other reading appears to have arisen from the conjecture of Origen, who found no such place on the Jordan as Bethany, but knew a town called Bethabara, where John was said to have baptized, and therefore took the unwarrantable liberty of changing the reading. (Orig. *Opp.* ii. p. 130, ed. Huet.)

BETHANY, a village nearly two miles E.S.E. from Jerusalem, beyond the Mount of Olives. It was the residence of Lazarus and his sisters Mary and Martha, and Jesus often went out from Jerusalem to lodge there. It is now a poor village of about twenty families. The only marks of antiquity are some hewn stones from more ancient buildings, found in the walls of some of the houses. The monks, indeed, show the house of Mary and Martha, and of Simon the leper, and also the sepulchre of Lazarus; but there is no reason to believe that this is the real tomb.

BETHEL, originally called LUZ, an ancient city on the borders of the tribe of Benjamin, twelve Roman miles north of Jerusalem. It was the place of Jacob's vision, and its name was consequently changed to Bethel, which signifies the "house or place of God." It is identified with the ruins at *Beitin*.

BETHESDA, called in the Greek κολυμβηθρα προβατικη, and thence in the Vulgate *piscina, probatica*, was the Hebrew name for a pool or public bath, which had five porticos, piazzas, or covered walks, around it. This bath was called Bethesda, בית חסרה, or *Beth-Chesda*, the "House of Mercy," probably because the erection of baths

Beth-horon. || Beth-lehem.

was a kindness to the poor. Some, however, will have the word Bethesda to be בית אשרה, *Beth-asda*, the "sink-house," or "drain," because the waters which came from the temple, and the place where the victims were washed flowed thither. From the use of the word κολυμβηθρα by Josephus, to denote the baths at Jericho, Dr Macknight, in his *Harmony of the Gospels*, concludes against such an opinion; and, moreover, he considers it inconsistent with the situation of Bethesda, which was near the sheep-gate or market in the S.E. wall of the city. That which is now and has long been pointed out as the pool of Bethesda, is a great dry basin or reservoir outside the northern wall of the inclosure around the Temple Mount; but there appears much reason to suppose that this was not the pool so called. (See *Robinson's Biblical Researches*, vol. i.) With regard to the precise nature of the miracle performed here there has been much diversity of opinion. Dr M ll contends that the text of the evangelist has been interpolated, and proposes to omit a verse not to be found in the Cambridge manuscript, which originally belonged to Beza. Dr Macknight strenuously opposes this method of interpretation; and while he maintains the integrity of the text, shows that Dr Mill's expedient leaves the difficulty exactly where it was. Grotius thinks that the angel is said to have descended, not because he was ever seen to do so, but because the Jews were persuaded that God brought such things to pass by the ministration of angels. And Dr Hammond supposes that the waters became medicinal by being impregnated with a healing warmth from the blood and entrails of the beasts offered in sacrifice that were washed there; and that the ἄγγελος, "angel," or "messenger," mentioned in the text, was a common messenger or servant of the priest, who at a proper season was sent by him to trouble the pool.

BETH-HORON, two places in Scripture distinguished as the Upper and Nether Beth-horon. Dr E. D. Clarke recognised the former in the village of *Beit-Ur*, which lies twelve Roman miles N.W. of Jerusalem. The Lower Beit-Ur is separated by a narrow valley from the foot of the mountain upon which the Upper Beit-Ur stands. Both these villages are inhabited, and exhibit traces of ancient walls and foundations. They are still distinguished as the Upper and Lower Beit-Ur. (Clarke's *Travels*, vol. i. part ii. p. 628.)

BETH-LEHEM (בית לחם, *house* or *place of bread*; Sept. Βηθλεέμ), a city of Judah, six miles southward from Jerusalem, on the road to Hebron. It was generally called Bethlehem-Judah, to distinguish it from another Bethlehem in Zebulun. Bethlehem is celebrated as the birth-place of David and of our Saviour, and as the scene of the Book of Ruth.

It has always been an inhabited place, and, from its sacred associations, has been visited by an unbroken series of pilgrims and travellers. It is now a large straggling village, and is beautifully situated on the brow of a high hill, which rises in parterres of vineyards, almond-groves, and fig plantations, watered by gentle rivulets that murmur through the terraces. At the farthest extremity of the town is the Latin convent, connected with which is the Church of the Nativity, said to have been built by the Empress Helena, and alleged to be the most chaste architectural building now remaining in Palestine. It is a spacious and handsome hall, consisting of a central nave amid aisles separated from each other by rows of tall Corinthian pillars of grey marble. Two spiral staircases lead to the cave called the "Grotto of the Nativity," which is about 20 feet below the level of the church, and is lined with Italian marbles, and lighted by numerous lamps. Here a star inlaid in the marble is said to mark the exact spot where the Saviour was born, and in a kind of recess, a little below the level of the rest of the floor, is a block of white marble, hollowed out in the form of a manger, to mark the place of the one in which the infant Jesus was laid. Although tradition is in favour of this being the place of the Nativity, there are many probabilities against it. The convent was long the abode of the learned and celebrated Jerome, and most of his works were composed here. Besides the Grotto of the Nativity, and the Tomb of Rachel, Bethlehem possesses three remarkable cisterns, which are supplied with water from a pool above the town: the largest is 582 feet by 207 feet at one end, and 148 feet at the other, with a depth of 50 feet; the central one is 423 feet by 250 feet and 160 feet, and has a depth of 39 feet.

Bethlehemites || Bethylus.

The inhabitants are said to be 3000, and were all native Christians at the time of the most recent visits. Their chief trade is in beads, crosses, and other relics. The people are remarkable for their ferocity and rudeness, which is indeed the common character of the inhabitants of most of the places accounted holy in the East.

The best accounts of modern Bethlehem are those of Clarke, Wittman, Richardson, Buckingham, Hardy, Elliot, Wilde, Robinson, Paxton, Olin, Prokesch, Richter, Schubert. See also Raumer's *Palästina*, pp. 307–313.

BETHLEHEMITES, or BETHLEMITES, in *Ecclesiastical History*, a sort of monks introduced into England in the year 1257, habited like the Dominicans, except that on their breast they wore a star with five rays, in memory of the star or comet which appeared over Bethlehem at the nativity of our Saviour. They were celled at Cambridge, and had only one house in England.

BETHPHAGE, a place between Jericho and Bethany, but of which the exact site is unknown.

BETHSAIDA, a town in Galilee, on the western side of the sea of Tiberias, not far from Capernaum. It was the native place of Peter, Andrew, and Philip, and the frequent residence of Jesus: the precise site, however, is utterly unknown, and the very name has long eluded the search of travellers, though Pococke and others have attempted to identify it with different places.

On the north-eastern border of the sea of Tiberias was another Bethsaida, near which Christ fed the five thousand, and probably also the one where the blind man was restored to sight. This and not the western was the Bethsaida of Gaulonitis, which was rebuilt and enlarged by Philip the Tetrarch, and received the name of Julias, in honour of Julia the daughter of Augustus.

BETHSHAN, a town of Samaria, in the half-tribe of Manasseh, on the borders of Galilee, about two miles from Jordan, and eighteen from the southern end of lake Gennesareth. It was also called Scythopolis, and by Josephus is said to be the largest city of the Decapolis. Its site is occupied by the small village of Beisan.

BETHULIA, a place which appears to have lain near the plain of Esdraelon on the south, not far from Dothaim, and to have guarded one of the passes towards Jerusalem. Modern ecclesiastical tradition identifies Bethulia with Safed, near the lake of Gennesareth, but Dr Robinson regards the site of Bethulia as still undetermined.

BETHUNE, MAXIMILIEN DE. See SULLY.

BETHUNE, a strongly fortified town of France, department of Pas de Calais, situated on a rock above the river Brette, 16 miles N.N.W. of Arras. Its castle was fortified by Vauban. It has a tribunal of primary jurisdiction, a communal college, a Gothic church, two hospitals, and manufacturers of linen, cloth, beer, &c. The trade, chiefly in grain, cheese, linen, and oil, is facilitated by the canal which unites the Lawe with the Lys. It was taken by the allied forces in 1710, and restored to France by the treaty of Utrecht. Pop. (1851) 7150. Area of the arrondissement of this name, 360 square miles; pop. 136,078.

BETHYLUS, one of Cuvier's genera of the family of Laniadæ, or shrikes, and also a genus of hymenopterous insects.

Betlis || Betterton.

BETLIS, or BITLIS, a town of Turkish Armenia, in Kurdistan, situated on the west shore of Lake Van in a highly-cultivated valley. Here the Armenians have four churches and as many monasteries, and they enjoy more courteous treatment than usually falls to their lot in Mahommedan countries. The houses are scattered over the valley, through which runs an extremely narrow road. The castle is situated on an eminence, so steep on all sides that it is only accessible by a road winding round it. Betlis is an ancient city, founded, according to the Armenians, by Alexander the Great. It is the centre of a considerable trade. The population of the town and neighbourhood is computed at about 10,000, Kurds, Turks, Armenians, and Syrians. Long. 42. 31. E. Lat. 37. 45. N.

BETROTHMENT, a mutual promise or compact between two parties for a future marriage between the persons betrothed. Betrothment amounts to what is called by civilians and canonists *sponsalia* or espousals.

BETTERTON, THOMAS, a celebrated actor, was the son of Mr Betterton, under-cook to King Charles I., and was born in Tothill Street, Westminster, in 1635. Having received some education, his fondness for reading induced his parents to accede to his desire to be apprenticed to a bookseller; and Mr Rhodes, near Charing Cross, was fixed on for his master. Rhodes, who had formerly been wardrobe-keeper to the theatre in Blackfriars, obtained in 1659 a license to set up a company of players at the Cockpit in Drury Lane; and there Betterton made his first appearance on the stage.

Soon after the Restoration, two different theatres were established by royal authority; the one in Drury Lane, in consequence of a patent granted to Henry Killigrew, Esq., which was called the "King's Company;" and the other in Lincoln's-Inn-Fields, the company of which styled themselves the "Duke of York's Servants." The patentee of the latter was Sir William Davenant, who engaged Betterton, and all Rhodes's company, and opened the theatre in 1662 with a new play of his own, called the *Siege of Rhodes*. Betterton became so great a favourite with the king, that by his Majesty's special command he went over to Paris to examine the French stage with a view to the improvement of our own; and it was after his return, as is generally supposed, that shifting scenes were first used in the English theatre instead of tapestry.

In 1670 Betterton married Mrs Sanderson, a performer on the same stage; and his union with this accomplished and excellent woman was productive of the greatest domestic felicity. When the duke's company removed to Dorset Gardens, Betterton and his wife continued with them; as also on the coalition of the two companies in 1684.

In 1693 Betterton was enabled to erect a new playhouse within the walls of the Tennis Court in Lincoln's-Inn-Fields. It was opened in 1695 with Congreve's *Love for Love*, which was very successful. Yet, in a few years the profits arising from this theatre, opposed as it was by all the strength of Cibber's and Vanbrugh's writings at the other house, were insignificant; and Betterton, infirm through age, and labouring under violent attacks of the gout, gladly quitted the fatigues of management and the bustle of the stage.

On his retirement, the public, in order to testify their respect for this theatrical veteran, gave him a benefit-night, when the comedy of *Love for Love* was performed, in which Betterton himself, though upwards of seventy years of age, sustained the youthful part of Valentine. Some months afterwards he acted that of Hamlet, his performance of which is particularly mentioned in the Tatler. The profits of the night are said to have amounted to upwards of L.500, the prices having been raised on the occasion.

The next winter Betterton was prevailed on by Mr Owen M'Swinney, then manager of the opera-house in the Haymarket, to lend his occasional aid; and in consequence of this arrangement, in the spring of 1710, there was given out for his benefit *The Maid's Tragedy*, of Beaumont and Fletcher, in which he performed his celebrated part of Melanthus. This, however, was his last appearance on the stage: his rash attempt to reduce the swelling of his limbs by external applications, threw the gout into his head, and terminated his life on the 28th of April. On the second of May his body was interred with much ceremony in the cloister of Westminster. Betterton was the author of several dramatic works, which were popular in their day. An estimate of his character and abilities may be seen in the *Apology for my own Life*, &c., of Betterton's friend and rival Colley Cibber.

Bettinelli.

BETTINELLI, XAVIER, one of the most celebrated Italian literati of the eighteenth century, was born at Mantua on the 18th of July 1718. After studying under the Jesuits in his native city and at Bologna, he entered in 1736 upon the noviciate of this society. He then undertook a new course of study; and afterwards taught the belles-lettres, from the year 1739 to 1744, at Brescia, where the Cardinal Quirini, Count Mazzuchelli, Count Duranti, and other scholars, formed an illustrious academy. He there began to distinguish himself by some pieces of poetry, composed as scholastic exercises. Being sent to Bologna to pursue the study of divinity, he continued to cultivate his poetical talent, and wrote also, for the theatre of the college, his tragedy of *Jonathan*. The number of learned and literary persons collected in this city exceeded by far what he had met with at Brescia. The Institute, recently founded by the Count Marsigli, the Clementine Academy of Design, the school of the astronomical poet Manfredi, the growing reputation of his ingenious and learned pupils Zanotti, Algarotti, and others, at this time fixed the attention of the literary world on Bologna. It was in the midst of this society to which he was admitted, that Bettinelli completed his education, and attained the age of thirty. He went in 1748 to Venice, where he became professor of rhetoric. He left it for various missions, and returned to it often. We may see by his epistles in free verse, or *sciolti*, that he was connected on friendly terms with all that this city and state could boast as most illustrious. He was destined by the superiors of his order for the oratorical department; but the weakness of his chest compelled him to relinquish it. The superintendence of the college of nobles at Parma was intrusted to him in 1751; and he principally directed the studies of poetry and history, and the entertainments of the theatre. He remained here eight years, but not without visiting, at intervals, different cities of Italy, either on the affairs of his order, for pleasure, or for health. In 1755 he undertook a longer journey, traversed part of Germany, proceeded as far as Strasburg and Nancy, and returned by way of Germany into Italy, taking with him two young princes, sons or nephews of the prince of Hohenlohe, who had requested him to take charge of their education. He made, the year following, another journey into France, along with the eldest of these two young princes, and lodged while in Paris at the College of Louis le Grand. It was during this excursion that he wrote the famous *Letters of Virgil*, which were published at Venice with his *sciolti* verses, and those of Frugoni and Algarotti. The opinions, and we may add without much hesitation the literary heresies, maintained in these letters against the two great luminaries of Italian poetry, and particularly against Dante, created him many enemies, and, what was still more unpleasant to him, embroiled him with Algarotti. Willing to know something more of France than Paris, he made several excursions into Normandy and other provinces: he went also into Lorraine, to the court of King Stanislaus, and thence proceeded to Lyons, and afterwards to Geneva. Soon after his arrival he went to visit Voltaire. This celebrated writer sent to his

Betula || Beudant.

inn an edition of his works, upon which was inscribed this stanza, in allusion to Bettinelli's *Letters of Virgil*:—

Compatriote de Virgile,
Et son sécretaire aujourd'hui,
C'est a vous d'écrire sous lui;
Vous avez son âme et son style.

From Geneva he proceeded to Marseilles, from thence to Nismes, and returned by Genoa to Italy and Parma, where he arrived in 1759. The same year he took a journey to Venice, and afterwards to Verona, where he resided till 1767. Having resumed the occupations of preaching and teaching, he, according to the Chevalier Pindemonti, converted the youth to God in the church, and to good taste in his own house. He afterwards lived for some years at Modena, and he had just been appointed professor of rhetoric there, when, in 1773, the order of Jesuits was abolished in Italy.

He then returned into his own country, where he resumed his literary labours with new ardour, and published in succession his *Correspondence between two Ladies*, his *Letters to Lesbia on Epigrams*, his *Letters on the Fine Arts*, and his *Twenty-four Letters on Love*. The siege laid by the French to Mantua had compelled him to leave it, and he retired to Verona, where he formed the most intimate friendship with the Chevalier Hippolito Pindemonti, notwithstanding the disproportion of their age. In 1797, after Mantua had surrendered, he returned thither. Though nearly eighty years old, he resumed his labours and his customary manner of life. He began in 1799 a complete edition of his works, which was finished at Venice in 24 volumes 12mo. Arrived at the age of ninety years, he still retained the gaiety and vivacity of his mind, and died on the 13th of September 1808. The following is a list of his works:—

1. *Ragionamenti Filosofici, con Annotazioni.* 2. *Dell' Entusiasmo delle Belle Arti.* 3. *Dialoghi d'Amore.* 4. *Risorgimento negli Studj, nelle Arti e ne' Costumi dopo il Mille.* 5. *Delle Lettere e delle Arti Mantouane: Lettere ed Arti Modenesi.* 6. *Lettere dieci ei Virgilio agli Arcadi.* 7. *Italian Letters from a Lady to her Friend on the Fine Arts*, and *Letters from a Friend.* 8. *Poetry*, 3 vols. 9. *Tragedies*, 2 vols. 10. *Lettere a Lesbia Cidonia sopra gli Epigrammi.* 11. An *Essay on Eloquence*, to which are added, some letters, discourses, and other miscellanies. (See *Biographie Universelle*, tome iv.) (W. H–Z–T.)

BETULA, the genus of plants to which our birch and its congeners belong. It gives its name to the *Betulaceæ*, one division of *Amentaceæ*. See BOTANY.

BETULEIUS, SIXTUS, a grammarian, Latin poet, and philosopher, born at Memmingen, A.D. 1500. His real name was Birck. He taught the belles-lettres and philosophy with reputation, and became principal of the college of Augsburg, where he died in 1554. He published various works in prose; and several dramatic pieces. See *Betuleii Vita, per Jo. Nyseum Scripta*; and Adam's *Vitæ Eruditorum*.

BETWAH, a river of Hindustan, which rises in the native state of Bhopal in Malwa, and pursuing a course of 360 miles, for the most part in a north-easterly direction, falls into the Jumna at Humeerpoor, in Lat. 25. 57. Long. 80. 17.

BEUDANT, FRANÇOIS-SULPICE. This eminent philosopher, born at Paris in 1789, was early distinguished for his skill in mineralogy, and his valuable labours in general physics and in geology. The work by which he established a European reputation was his *Voyage Minéralogique et Géologique en Hongrie*. It appeared in 1822, in 4 vols. 4to, the last of which consisted of geological maps, designs, and sections, that attest the care with which he examined that interesting country. This great work is divided into two parts. After an introduction on the geography, population, government, natural productions of Hungary, tables of latitudes and longitudes, of barometric determinations of the heights of its mountains, &c., the first two volumes contain what he terms *Relation Historique*, giving an admirable account of his various journeys, including the best extant description of its mines, mineralogy, and geology. The general disquisitions on these, however, are reserved for the second part; which he has judiciously thus separated from the thread of his narrative, and discussed with remarkable fairness and candour. He appears to have at first adopted the Wernerian classification of rocks, but those of Hungary he divides into primitive, intermediate, secondary, tertiary, and independent,—meaning by the last the formations, or, as he styles them, the *terrains* of trachytes and basalts; which form so conspicuous a feature in the geology of Hungary, and which he has distinctly proved to have an igneous origin; but his deductions are stated with considerable impartiality and modesty, qualities not always found in geological works.

Beutelspach || Beveridge.

Beudant was advantageously known also as a mechanical philosopher, as the sixth edition of his *Traité Elémentaire de Physique* of 1838 sufficiently shows. His excellent elementary work on mineralogy went through two editions before it was enlarged in his *Cours Elémentaire de Minéralogie et de Géologie*, 18mo, in 1841. The same year exhibits him also as a philologist in his *Nouveaux Elémens de Grammaire Française*, 12mo.

Besides these works, he enriched several periodicals by his numerous communications, as *Annales de Chimie*, vols. iv., viii., xiv., xvi., xxxi., xxxviii; *Annales du Museum d'Histoire Naturelle*, vols. xv., xvi.; *Annales des Mines*, vols. iii., xii.; and *Memoires de l'Académie des Sciences*, vol. viii. Beudant died at Paris in 1852, in the sixty-fifth year of his age. (T. S. T.)

BEUTELSPACH, a town in the circle of Jaxt, kingdom of Wirtemburg. It stands on the river Beutel, and is remarkable as containing the ancient monastery and church in which is the cemetery of the ducal house of Wirtemburg. It contains 1900 inhabitants, chiefly employed in the manufacture of wine, which is of excellent quality.

BEUTHEN, two small towns in the Prussian province of Silesia. The one is capital of a circle of the same name in the government of Oppeln, and contains 6106 inhabitants, engaged in the manufacture of linen and woollen goods, and earthenware; the other is in the government of Liegnitz and circle of Freistadt, on the Oder, and has a population of 3824.

BEVEL, an instrument used by artificers for drawing angles. It consists of two limbs resembling those of a square, but which are moveable on a pivot at the joint in order to adjust it to any angle. The edge of the blade is sometimes curved, to suit the sweep of an arch or vault.

BEVEL-Angle, any angle except a right angle, whether it be acute or obtuse.

BEVELAND, NORTH and SOUTH, the name of two Zealand islands, formed by the divided branches of the Scheldt. North Beveland is about six miles in length by four in breadth. It lies to the east of the island of Walcheren, and between it and South Beveland is the island of Wolfersdyke. The inundation of 1532 completely ruined it. For many years it remained immersed in water, and was only again formed into an island by the gradual deposits of the sea. South Beveland is twenty-four miles long by from five to eight broad. It contains the town of Goes, and several forts and villages. An active trade in corn is carried on here, and the place is considered one of the most agreeable of the Zealand islands.

BEVERAGE, any liquor for drinking. In the middle ages, *beverage*, *beveragium*, or *biberagium*, was money for drink given to an artificer or other person over and above his hire or wages.

BEVERIDGE, WILLIAM, a very learned English bishop, was born at Barrow in Leicestershire, A.D. 1638, and educated at St John's College, Cambridge, where he distinguished himself very early by his extensive learning, and

Beverley ‖ Bevin.

particularly by his knowledge of the Oriental languages. Upon the deprivation of Dr Thomas Ken, bishop of Bath and Wells, for not taking the oaths to the government in 1691, he refused the offer of that see, although he was then chaplain to King William and Queen Mary. In 1704 he was consecrated to the bishopric of St Asaph, and discharged the duties of that office in an exemplary manner. He died at his apartments in the cloisters of Westminster Abbey in 1707, aged sixty-nine. His whole life was spent in acts of piety and charity, and he gave remarkable instances of both at his death, leaving the bulk of his estate for the propagation of the gospel and the promotion of Christian knowledge at home as well as abroad. His *Private Thoughts upon a Christian Life* is a very popular book. He was the author of several valuable works, particularly on the Oriental tongues.

BEVERLEY, a market and borough town in the East Riding of Yorkshire, about a mile from the river Hull, with which it communicates by means of a canal called the Beverley Beck. It is a very neat and handsome town, consisting principally of one long wide street upwards of a mile in length, and terminated by an ancient gateway. The magnificent collegiate church of St John is in size and splendour superior to many cathedrals. Having been erected at different times it exhibits various styles of Gothic architecture. The west front is said by Rickman to be the finest of its kind in England. It is 334 feet in length from east to west; the breadth of the nave and side aisles is 64 feet; the transept is 167 feet long; and the two towers at the west end are 200 feet in height. St Mary's church is also an exceedingly handsome and spacious Gothic building. The market-place, which comprises an area of nearly four acres, is ornamented with an octangular market-cross. The grammar-school is of great antiquity, and has two fellowships, six scholarships, and three exhibitions at St John's College, Cambridge. There are several national and two infant schools, Blue-coat school, mechanics' institute, newsroom, four banks, savings bank, dispensary, theatre, jail, &c. Its trade is chiefly confined to tanned leather, oatmeal, malt, corn, and coal. Market-days, Wednesday and Saturday. It is governed by a mayor, six aldermen, and eighteen councillors; and returns two members to parliament. Pop. (1851) of parliamentary borough, 10,058; of municipality, 8915.

BEVERLEY, a sea-port of Massachusetts in North America, connected with Salem by a bridge. It is sixteen miles N.E. of Boston. Pop. 4689.

BEVERLEY, *John of* (*Joannes Beverlacius*), archbishop of York in the eighth century, was descended of a noble family at Harpham in Northumberland, and was one of the most learned men of his time. He was abbot of the monastery of St Hilda, when his merit recommended him to the favour of Alfred king of Northumberland, who in 685 advanced him to the see of Hagustald or Hexham, and in 687 translated him to the archbishopric of York. This prelate was tutor to the famous Bede, and lived in the strictest friendship with Acca and other Anglo-Saxon doctors, several of whom he engaged to write comments on the Holy Scriptures. In 704 he founded a college at Beverley for secular priests; and after he had governed the see of York thirty-four years he divested himself of his episcopal character, and retired to Beverley, where he died four years after, on the 7th of May 721. Bede and other monkish writers ascribe several miracles to him. He wrote, 1. *Pro Luce exponenda;* 2. *Homiliæ in Evangelica;* 3. *Epistolæ ad Hildam Abbatissam; Epistolæ ad Herebaldum, Andenum, et Bertinum.*

BEVILE, in *Heraldry*, a thing broken, or opening like a carpenter's rule.

BEVIN, ELWAY, a musician eminently skilled in the art of composition, who flourished towards the end of Queen Elizabeth's reign. He was of Welsh extraction, and had been educated under Tallis, upon whose recommendation he was in 1589 sworn in gentleman extraordinary of the chapel; but from this situation, as well as from that of organist of Bristol cathedral, he was expelled in 1637, for his adherence to the Romish communion. He composed several services and anthems, and wrote a treatise on composition entitled the *Art of Musicke.*

Bewdley ‖ Beykaneer

BEWDLEY, a market and borough town in the parish of Ribbesford, in the county of Worcester, 129 miles from London. It is a well-built town, and is situated on an eminence near the river Severn, over which there is an elegant bridge. It has a modern town-hall, a free grammar-school, and several charities; with manufactures of combs, leather, and malt. It is governed by a mayor, four aldermen, and twelve councillors, and returns one member to parliament. Pop. in 1831, 3908; in 1851, 3124. This decrease is attributed to the decline of its transit trade by means of the river, which was formerly considerable.

BEWICK, THOMAS, a celebrated engraver on wood, born at Cherryburn, near Newcastle-on-Tyne, in 1753. He may be considered as the reviver of wood-engraving in Britain, and obtained a premium for a work in 1775 from the Society of Arts. He is well known for his illustration of *Select Fables*, which appeared in 1784; his *Quadrupeds*, published in 1790; and his *British Birds*, which appeared from 1797 to 1804. This last is his masterpiece, and exhibits him as a naturalist as well as an engraver. Our best artists on wood are Bewick's pupils. He died in 1828. A good memoir of him may be found in the *Gentleman's Magazine* for 1829. See WOOD-ENGRAVING.

BEWITS, in *Falconry*, pieces of leather to which a hawk's bells are fastened, and buttoned to his legs.

BEY, the Turkish governor of a town or district.

BEYAH, a river of Northern India, rising in the Himalayan province of Lahoul, in Lat. 32. 24. Long. 77. 11., at an elevation of 13,000 feet above the level of the sea. For the first 80 miles of its course the river takes a southerly direction to Mundi, whence turning westward it flows for the distance of 50 miles to Nadaun. From this point it makes a wide sweep of 80 miles to the N.W., and, entering the plains of the Punjaub, proceeds in a southerly direction to its confluence with the Sutlej; the whole length of its course being 290 miles. The Beyah is identical with the Hyphasis, which formed the limit of Alexander's expedition. Below its junction with the Sutlej the united streams bear the name of the Ghara. (E. T.)

BEYKANEER, or BICANERE, one of the native states of Rajpootana in the N.W. of Hindustan, bounded on the north by the British district of Butteeana; on the E. and S.E. by the native state of Shekawuttee; on the south by Joudpore; and on the west by Jessulmere and Bahawulpore. It extends from Lat. 27. 30. to 29. 55., and from Long. 72. 30. to 75. 40. and contains an area of 17,676 square miles, with a population of about half a million, consisting of Rajpoots and Jauts; the former being the rulers, the latter constituting the mass of the people.

A vast proportion of the soil of Beykaneer is a barren sandy desert, or a hard flat clay, sounding like a board under horses' feet, and entirely destitute of inhabitants, water, and vegetation. Hills and valleys of loose and heavy sand extend for many miles; the former, from twenty to a hundred feet in height, shifting their position and altering their shape according to the influence of the wind. During the heat of summer, clouds of moving sand threaten to overwhelm the traveller; and this desert sometimes exhibits the deceitful illusions of the *mirage.*

Vegetation is exceedingly scanty throughout, except in in a few patches, which are skilfully and industriously cultivated; and the whole country seems to depend on external supplies of grain. Nevertheless, in the midst of arid tracts, the water-melon, a juicy fruit, grows in profusion, attaining the remarkable size of three or four feet in circum-

Beykaneer

ference, from a stock no larger than that of the common melon. The seeds are sown by the natives, and also grow wild; but it is difficult to account for such an enlargement of size with so little moisture. There are no permanently running streams in Beykaneer. Water seems to be obtained only at an immense depth. The wells are often from 300 to 345 feet in depth, yet not above three in diameter; they are all lined with masonry; and one of the most curious objects in the city of Beykaneer is considered to be a well 300 feet deep, and fifteen or twenty in diameter, worked by four pair of oxen drawing as many buckets of water. The water is always brackish, scanty, and unwholesome; and this, combined with the nature of the soil, principally occasions the prevalent sterility of the country.

The wild ass, remarkable for its speed and its shyness, is found here, sometimes solitary, but oftener in herds. At a kind of shuffling trot peculiar to itself, it will leave the best horses behind. Antelopes are seen in some parts; also foxes, but smaller than those of Britain; and the desert rat is found in great numbers, occasioning serious inconvenience to equestrians, from the holes it makes where the ground is sufficiently solid. Of domesticated animals, horses, bullocks, and camels, are abundant; the last being kept in great herds for various purposes. The horses brought from the vicinity of the Johur jungle, an adjoining district, where they are reared on excellent pasture and with the strictest attention, are much prized.

The only towns of importance are Beykaneer the capital of the province, and Churoo on the eastern frontier. Churoo, independent of the suburbs, is above a mile and a half in circuit, and although situate among sandhills has a handsome appearance. All the houses have terraces, and are built of a pure white limestone. Beykaneer is situate in a remarkably desolate tract. It is surrounded by lofty white walls, strengthened with numerous round towers crowned by battlements, and presents the imposing picture of a great and magnificent city in the midst of a wilderness. But on entering the gates the illusion vanishes; and it is found to consist, for the most part, of huts built of mud, and painted red. Nevertheless there are some high houses, several temples, and at one corner a lofty and fine-looking fortress, a quarter of a mile square, environed by a wall thirty feet high, and a good dry ditch. The interior is a confused assemblage of towers and battlements, overtopped by houses; and it contains the royal palace, a curious old edifice.

Beykaneer is governed by a rajah, who acknowledges the supremacy of the British government. His dominions were wrested chiefly from the Batties about the middle of the fifteenth century by a younger son of the rajah of Joudpore, who founded the principality. In the following century his successors appear among the feudatories of the Mogul emperors of Delhi, in which relative position they seem to have continued until the decay of the empire, when they recovered their independence. In 1799 George Thomas, a celebrated adventurer, who raised himself to the government of a neighbouring territory, invaded Beykaneer, and compelled the rajah to purchase peace with a tribute of L.25,000. He also aided the Batties in expelling him from their country. More recently, a war having commenced between the rajahs of Joudpore and Jeypore, who were contending for the hand of an eastern princess, the interference of Soorut Sing of Beykaneer excited the wrath of some of the competitors against himself. Five different armies invaded Beykaneer in 1808, when the rajah filled up all the wells within ten miles of the walls of his capital. The contest was protracted for a considerable time, but the rajah succeeded in maintaining himself as an independent prince. His independence was finally secured to him by his being admitted, in 1818, within the line of British protection. The rajah maintains a military force of 3500 men, irrespective of the quotas furnished by his feudal chiefs, amounting to 1500 horse. His revenues are returned at L.65,000 per annum. Distance of Beykaneer N.W. from Calcutta 1175 miles. Lat. 28 N.; Long. 73. 22. E. (J. G. D.) (E. T.)

Beyra || Beyrout.

BEYRA or BEIRA, a province of Portugal, bounded on the north by the provinces of Traz-os-Montes and Minho; east by Spain; south by Alentejo and Portuguese Estremadura; and west by the Atlantic. Area about 5900 square miles. Pop. (1850) 631,416. The surface is very mountainous; its highest point, in the Sierra de Estrella, being 7524 feet. It is divided into Beira Alta and Beira Baixa; the former comprising the district between the Douro and the Sierra de Estrella, and the latter the remaining portion of the province between these mountains and the Tagus. The principal river is the Douro, which receives the waters of numerous smaller streams. The other chief rivers are the Aguada, the Mondego, the Vouga, and the Zezere. Agriculture is in a neglected state, and before the general introduction of the potato an annual importation of foreign corn was necessary for the support of the inhabitants. On the mountains and in the valleys, however, sheep are pastured in great numbers, and the olive is extensively cultivated; olive-oil and fruit forming the principal exports of the province. Good wine also is produced, and the cheese of the Sierra de Estrella district is famed. Silver and lead ores exist in some of the mountains, but the mines have not been wrought since a remote period. Iron, coal, and marble, are worked to some extent. There are few manufactures, the chief employment being the cultivation of the vine, the olive, the chestnut, the orange, &c.

The province comprehends 7 bishoprics, 22 judicial districts, 85 communes, and 860 parishes. The chief towns are Coimbra, Viseu, Aveiro, Ovar, and Lamego. The heir-apparent to the throne of Portugal has the title of Prince of Beira.

BEYRAMICH, a city of Asia Minor, the capital of the district called Troas, which belongs to the pasha of the Dardanelles. It is an extensive town, and the houses are better built and more regularly disposed than in Constantinople. Many antiquities are to be seen in this place and the vicinity; amongst which are several sarcophagi, consisting of entire blocks of granite, converted to ordinary purposes in the street. It is distant about sixty miles from the Dardanelles.

BEYROUT, BEIROUT, or BAIRUT, anciently BERYTUS (Βηρυτός), a seaport-town of Syria, in the pashalic of Saide or Acre. A tongue of land, which presents a conspicuous headland when viewed from the north, extends itself in a plain about five or six miles from the mountains towards the sea; and on the northern edge of this plain the town is situated, on a rising ground, which contributes both to its cleanliness and salubrity. To the north the projection of the land forms a fine bay, the head of which is five or six miles E.S.E. of the town; and there is thus a roadstead to the N.E., secured from the S.W. wind, which is the prevailing one. The harbour is now choked up with sand and rubbish; and all that remains of the ancient structure is a pier, to which boats can approach sufficiently for discharging goods. All along its front are ranged fine shafts of gray granite pillars, which are used for mooring small vessels. Merchant vessels and ships of war anchor at a distance in the roadstead. The town itself is an irregular square, open towards the sea, and surrounded on the three sides which face the land with a wall built by Djezzar Pasha, defended by a few round towers of little strength, and far too feeble to resist an attack of artillery. Near the sea is an old castle, on which are six pieces of artillery; and at the common landing place is a ruined tower, built on a rock in the sea. The town is in general better built, and the situation is more salubrious than any along the coast; the streets are wider, and are paved with large stones. The dwelling-houses are spacious, lofty, and well built; the bazaars are amply furnished with provisions, as well as with Oriental and European manufactures;

Beys ‖ Beza.

and the magazines near the sea-shore are large and convenient. The town contains three mosques, with their courts, fountains, and minarets; and four Christian churches. Water is abundantly supplied at all seasons from several fountains, constructed by Djezzar Pasha. The suburbs are nearly as large as the town; consisting of houses interspersed with gardens, which are planted with fruit-trees, and are extremely beautiful. "The situation," says Mr Carne, "is the most beautiful of all the Syrian towns: the environs are laid out in plantations of mulberry trees, and a quantity of silk is produced and exported." Indeed, the commerce of Beyrout is greater than that of any other port in Syria; and it is increasing. It is the maritime emporium of Damascus, and of the surrounding country. British manufactures, such as cottons, muslins, cloths, &c., with bar-iron, lead, coffee, spices, indigo, &c., are imported. The returns are made in cotton, corn, raw silk (which is the staple commodity of the country), sometimes in wine and oil, and occasionally in specie. The population, amounting to about 12,000, is composed of Druses, Maronites, Greeks, Turks, Jews, Arabs, Africans. A Greek and a Maronite bishop reside here. Beyrout still boasts some relics of the ancient magnificence of Berytus, that celebrated "nurse of tranquil life" (Βηρυτὸς βιότοιο γαληναιόο τιθήνη), as Nonus has called it (*Dionysiaca*, lib. xli. p. 708. ed. Falk. Antv. 1569). The school of jurisprudence, founded here in the third century, long maintained a high reputation. During the reign of Justinian, the two imperial cities and Berytus were the only places within the limits of the empire where law was permitted to be publicly taught; and of the three, the Syrian school (of which Theophilus and Dorotheus, the associates of Tribonian in the compilation of the *Institutions* and the *Digest* were *antecessores* or teachers) appears to have stood highest in general estimation. But the prosperity of Berytus was first interrupted, and finally subverted, by some of the great convulsions of nature. In the year 384 the town was greatly injured by an earthquake, and in 554 it was visited by another which left it a heap of ruins. After this last catastrophe the professors transferred their school to Sidon, and the surviving inhabitants made an effort to raise a new city from the ruins of the old; but another calamity awaited them, and this famous seat of jurisprudence was totally consumed by fire. After a long interval, the modern town of Beyrout was founded by the Druses near the ancient site, and was possessed by the emirs as their capital and only seaport, until they were expelled by Djezzar Pasha of Acre. Beyrout is an important possession in connection with the power of Turkey in the East. In 1840 it was bombarded by the combined fleets of England and Turkey, and wrested from the hands of the pasha of Egypt. Long. 35. 29. E. Lat. 33. 50. N. (Buckingham's *Travels among the Arab Tribes;* Volney's *Travels;* Carne's *Letters from the East;* Jowett's *Christian Researches in Syria*, &c.; Lamartine's *Travels in the East.*)

BEYS, Giles, a celebrated printer at Paris in the sixteenth century, who first made a distinction in printing between *i* and *j*, *u* and *v*.

BEZA, or Besze, Theodore, one of the principal pillars of the reformed church, was born at Vezelai in Burgundy, June 24. 1519. He was sent early to Paris to his uncle Nicholas Beza, who was counsellor to the parliament; and at nine years of age he became a student at Orleans. He afterwards went to Bourges, where, under the care of Melchior Wolmar, he made extraordinary progress in learning, and imbibed the principles of Calvinism. His uncle intended him for the bar; but the law not suiting his disposition, he spent most of his time in reading the Greek and Latin authors, and in composing verses. In 1539 he took his licentiate's degree, and went to Paris, where he yielded to the allurements of pleasure, and wrote some poems of a licentious cast. But sickness awakened him to a sense of his error, and he determined to perform a vow he had formerly made of entering into the reformed church. With this resolution he went to Geneva and made a public profession of the reformed religion. In 1549 he accepted the Greek professorship at Lausanne, where he also read lectures in French on the New Testament. Having settled at Geneva, he adhered to Calvin in the strictest manner, and became his colleague in the church and in the university. At the solicitation of some great men of the kingdom he was sent to Nerac to confer with the king of Navarre upon affairs of importance. At this time the Guises had gained authority, under the reign of Francis II., to the prejudice of the princes of the blood. The king of Navarre having testified both by letters and deputies that he desired Beza might assist at the conference of Poissy, the senate of Geneva consented. The assembly listened attentively to his harangue, till, speaking of the real presence, he said, that the body of Jesus Christ was as distant from the bread and wine, as the highest heaven is from the earth. This produced a murmur: some cried out, "Blasphemavit;" and others rose up to go away. Cardinal de Tournon, who sat in the first place, desired the king and queen either to silence Beza, or to permit him and his company to withdraw. The king did not stir, nor did any of the princes; and leave was given him to proceed. Throughout the whole conference he acquitted himself with great ability. He often preached before the queen of Navarre, the prince of Condé, and in the suburbs of Paris. After the massacre of Vassy, he was deputed to the king to complain of this violence. The civil war followed soon after, during which the prince of Condé kept Beza with him; and while the prince was imprisoned he lived with Admiral de Coligni, and did not return to Geneva till after the peace of 1563. In 1571 he was chosen moderator of the national synod of Rochelle, and assisted the year after at that of Nismes; after which he was present at the conferences of Montheliard, and at those of Berne. The infirmities of age beginning to fall heavily upon him, he seldom spoke in public, and in the beginning of 1600 ceased to do so entirely. In 1597, however, he wrote some animated verses against the Jesuits, on the occasion of a report that was circulated of his death, and of his having embraced on his deathbed the Romish faith. He died on the 13th October 1605. Beza was a man of extraordinary merit, and did great service to the Protestant cause. This, however, exposed him to innumerable calumnies; but his adversaries, both Catholic and Lutheran, found that he was well able to defend himself.

Beza wrote, 1. A Translation of the New Testament; 2. A Version of the Psalms into Latin verse; 3. A treatise on the Sacraments; 4. Some Sermons on the Passion of Jesus Christ and on Solomon's Song; 5. A version of the Canticles, in lyric verse; 6. A French tragi-comedy, entitled The Sacrifice of Abraham; and many other works.

Bezant ‖ Beziers.

BEZIERS, a city of France, in the department of Herault, and capital of an arrondissement of the same name. It is beautifully situated on a hill, on the left bank of the river Orbe, where it is joined by the canal of Languedoc, 38 miles S.W. of Montpelier. It is surrounded by old walls flanked with towers, round which is a recently planted promenade; and has a fine old Gothic cathedral, several churches, an old episcopal palace now used for the government offices, a communal college, agricultural society, theatre, and public library. It manufactures silk stockings, starch, gloves, brandy, confectionary, paper, leather, glass, &c.; and has a considerable trade. Beziers is of great antiquity, and has remains of an amphitheatre and other Roman works. The Romans established a colony here in 636; and afterwards it became the head-quarters of the seventh legion, under the title of *Biterra Septumanorum.* It was completely destroyed in 1209 by the forces of Simon de Montfort in the crusade against the Albigenses, on which occasion 60,000 persons were

Bezoar || Bheels.

barbarously massacred. Beziers was rebuilt in 1289, and again suffered severely in the civil and religious wars of the sixteenth century. Pop. (1851) 17,376.

BEZOAR. This name, which is derived from a Persian word implying an antidote to poison, was given to a concretion found in the stomach of an animal of the goat kind, and once very highly valued for this imaginary quality; and hence it has been extended to all concretions found in the intestines of animals. Of these there are several kinds; first, superphosphate of lime, which forms concretions in the intestines of many mammalia; secondly, phosphate of ammonia and magnesia, a concretion of a gray or brown colour, composed of radiations from a centre, and found in the intestines of herbivorous animals, such as the elephant, the horse, &c.; thirdly, biliary concretions, of a reddish brown colour, and frequently met with in the intestines and gall bladders of oxen. This kind is composed of inspissated bile, and is used by painters as an orange-yellow pigment. Such concretions also occur hairy, resinous, and ligniform.

BHADRINATH, a town and celebrated temple in Hindustan, in the British district of Gurwhal, situate on the right bank of the Vishungunga, a tributary of the Alcanunda river, in the middle of a valley nearly four miles in length and one in breadth. The town is small, containing only twenty or thirty huts, in which reside the Brahmins and the attendants on the temple. The building, however, which is considered a place of high sancity, by no means corresponds to its great celebrity. It is about 40 or 50 feet in height, built in the form of a cone, with a small cupola, on the top of which is a gilt ball and spire, and contains the shrine of Bhadrinath, dedicated to an incarnation of Vishnu. The principal idol is of black stone and about three feet in height. Bhadrinath is the favourite resort of pilgrims from all parts of India. In ordinary years the number varies from 7000 to 10,000; but every twelfth year, when the festival of Kumbh Mela is celebrated, the concourse of persons is said to be 50,000. In addition to the gifts of votaries, the temple enjoys a further source of revenue from the rents of villages assigned by former rajahs. Some years since the temple was shattered by an earthquake, and has only been partially restored. It is situate among mountains rising 23,000 feet above the level of the sea. Elevation of site of the temple 10,294 feet. Lat. 30. 44. Long. 79. 32. (E. T.)

BHATGAN, or BHATGONG, a town of Northern Hindustan, in the valley of Nepaul, and a celebrated place of Hindu superstition. It is the favourite residence of the Brahmins of Nepaul, and contains many more families of that order than either Catmandoo or Patu. It contains 12,000 houses, and its palace and the buildings in general are of a more striking appearance than those of the other Nepaulese towns. The town is said to contain many valuable Sanscrit libraries. Lat. 27. 37. N. Long. 85. 22. E.

BHEELS, one of the rude tribes of Hindustan, inhabiting chiefly the rocky ranges of the Vyndhia and Sautpoora mountains, and the banks of the Nerbudda and Taptee. In common with the hill tribes designated Coolies and Ghoonds, the Bheels are supposed to have been the aborigines of India, and to have been driven to their present fastnesses at the period of the Hindu invasion. They are of dark complexion and diminutive stature, but active, and capable of enduring great fatigue. Efforts have been made by the British government to reclaim the Bheels from lawless practices; and these have been rendered successful, partly by raising a local military corps into which the wild and unruly spirits were drafted, and partly by settling throughout the districts of Candeish and Ahmednuggur small agricultural communities composed of those more peaceably disposed. High commendation has been bestowed by competent military authority upon the discipline and skill displayed by the Bheel corps; while with regard to the agricultural settlements, the happy results cannot be better described than in the words of the British superintendent Mr Candeish, who says: "These districts, formerly the scene of every outrage, where neither life nor property were secure, now enjoy tranquillity; the roads, formerly hazardous for an armed party, are traversed at all hours by single passengers; the formidable list of crimes has dwindled down to the reports of a few petty thefts, and the Bheels from outcasts have become members of a society daily rising in respectability and appearance, and becoming useful and obedient servants of the state." (E. T.)

Bhurtpore.

BHURTPORE, a town of Hindustan, and the capital of a native state of the same name. It is a place of great extent, the site occupied by the town and fort measuring upwards of eight miles in circumference. It had also in former times the reputation of considerable strength; being surrounded by a mud wall of great height and thickness, with a very wide and deep ditch. The fort stands at the eastern extremity of the town; its situation is more elevated, its walls are higher, and its ditch is of greater width and depth. It is of a square figure; one of its sides originally overlooked the country, while the other three were within the town, but since the enlargement of the city, which took place after the siege of 1805, the fortress has been brought entirely within the city walls. The ditch, from the nature of the ground, may be easily filled from an adjoining lake, and being thus rendered unfordable, presents a formidable obstacle to a besieging army. The rajah of Bhurtpore and most of his people are Jauts. It was in 1700 that this tribe first attracted notice in Hindustan. They migrated from the right bank of the Indus into the province of Mooltan, and were allowed to settle in several parts of the country between the Ganges and the Jumna. They are, according to Bishop Heber, the finest people in point of bodily advantages and martial spirit that he had seen in India; and their country is one of the most fertile and best cultivated. Chooraman, their elected leader, is said to have erected the fortress of Bhurtpore at the commencement of the eighteenth century, by means of the plunder which he had carried off from Aurungzebe's army during its retreat from the Mahrattas towards Ahmednuggur. He transmitted this stronghold to his successors, by one of whom it was held at the time the British advanced into Central India. In 1803 a treaty of perpetual friendship was concluded between him and General Lake; but, notwithstanding this, he espoused the declining cause of Holkar in 1804, and admitted his routed army into the fortress. Lord Lake reached Bhurtpore on the 3d January 1805, and forthwith commenced a series of operations against the fort. A breaching battery of six eighteen-pounders, and one of four eight-inch, and four five-inch mortars, were the means of attack. The British army, from its limited numbers compared with the extent of the place, acted under every disadvantage. Their operations were confined to one point, and the besieged consequently could easily procure supplies from the surrounding country. Undismayed by these obstacles, Lord Lake made four successive attempts to storm the fortress, in all of which he was repulsed with great slaughter; his loss amounting, in killed and wounded, to about 3000. The rajah, notwithstanding his success, fearing that British courage and skill would ultimately prevail, sent his son to Lord Lake's camp with the keys of the fortress, and agreed to compel Holkar to quit Bhurtpore. A second treaty was then concluded with the rajah, and several additional precautions adopted to secure his fidelity. This signal overthrow of the British by the Jauts, the defenders of Bhurtpore, was celebrated all over India, and was by many regarded as the forerunner of their expulsion from Hindustan. But in the lapse of twenty years an opportunity occurred for a new trial of strength, which terminated in the complete triumph of the British arms. A dispute occurred in the family of the rajah respecting the succession;

Biafra ‖ Bible.

the cousin having usurped the inheritance of the son. Sir David Ochterlony prepared to expel the usurper, but was restrained by orders from the governor-general. Afterwards, however, it was determined to attack this great stronghold; and on the 10th December 1825 Lord Combermere assumed the command of the British army before Bhurtpore. As it was vain to batter in breach, on account of the extraordinary thickness of the wall, the besiegers proceeded by mining; and on the 18th January 1826, a mine of considerable dimensions having been first sprung, the signal was given for the assault. In the course of two hours every gateway and bastion, and the whole rampart surrounding the town, with the gates of the citadel, were in possession of the besiegers, and thus was effaced the transient stain which the former failure at Bhurtpore had cast on the glory of the British arms. On the 4th February the rightful rajah was reinstated in his inheritance; and some years after, on attaining his majority, was admitted to the exercise of independent authority. It was at the same time determined to dismantle the fortress; and the principal bastions, and parts of several curtains, were accordingly blown up, and left in a state of ruin. The territory of which Bhurtpore is the principal place has an area of 1978 square miles, and contains a population of 600,000. Its revenue is computed at L.170,000 per annum, and its ruler maintains a military force of 200 artillery, 1500 cavalry, and 3700 infantry. Bhurtpore is thirty-four miles N.W. from Agra. Lat. 27. 13. Long. 77. 33. (E. T.)

BIAFRA, a tract of country on the coast of Western Africa, on a bay or bight of the same name, situated at the easternmost extremity of the Gulf of Guinea. It has long been known that a number of broad estuaries open into this bight from the north; but, owing to a strange want of enterprise, or some other cause, European vessels trading on this coast have not hitherto ascended any of these beyond fifty or sixty miles from its embouchure. Lander the traveller, however, in descending the Niger, arrived by one of these channels in the Bight of Biafra; thus solving the great problem of African geography, and leaving no doubt that the system of inter-ramified river-channels, extending from Benin to Biafra, constitutes the delta of the Niger, through which, by a number of outlets, it discharges itself into the sea. For the details of this important and interesting discovery, see the article NIGER.

BIAFRA, *Bight of*, the most eastern part of the Gulf of Guinea, on the western coast of Africa, between Capes Formosa and Lopez, and containing the islands of Fernando Po, Prince, and St Thomas.

BIALYSTOCK, a fortified town of European Russia, capital of a province of the same name, which formerly formed part of the kingdom of Poland. It is situated on the Bialy, an affluent of the Narew, and is neat and well built, having a castle, four churches, a gymnasium, and a considerable trade. Pop. 9217. It is 45 miles S.W. of Grodno, in Lat. 53. 7. 35. N. Long. 23. 20. E.

Bianchi ‖ Bible.

BIANCHI, FRANCESCO, called Il Frari, an eminent painter, born at Modena in 1447; died in 1510. He had the honour of being the instructor of Coreggio.

BIANCHINI, FRANCIS, a very learned Italian astronomer and philosopher, born at Verona in 1662, of a noble and ancient family. His taste for natural philosophy and mathematics induced him to establish the academy of Alcotofili, at Verona. He went to Rome in 1684, and was made librarian to Cardinal Ottoboni, afterwards Pope Alexander VIII. He also became canon of St[a] Maria de la Rotonda, and at length of St[o] Lorenzo in Damaso. He was the author of numerous works, and died in 1729.

BIAR, a town of the province of Alicante, in Spain, containing about 3000 inhabitants, who are employed in making woollen goods. The vicinity is celebrated for its honey, which has a peculiar flavour, extracted from the rosemary, which grows wild there in great abundance.

BIARCHUS (*βίαρχος*), in the court of the emperors of Constantinople, an officer who superintended the provisions of the soldiery.

BIAS (*Βίας*), of Priene in Ionia, one of the Seven Sages of Greece, flourished about 550 years before Christ. He was accustomed to say, that it was a sickness of the mind to wish for impossible things. Being asked, when his native city was besieged, why he alone had retired from the place without carrying anything with him, he replied, that he carried his all with him; meaning, that knowledge and virtue were the only blessings peculiarly his own, since they could not be taken from him. He lived to a very advanced age, and expired immediately after pleading successfully the cause of one of his friends. Diogenes Laertius and others have recorded many of his sayings.

BIAS, the inclination or bent of the mind to a particular object. It is also applied to the weight inserted in the side of a bowl, which causes it to incline, when rolling, to that particular side.

BIBERACH, a town of Würtemberg, in the circle of the Danube, and capital of a bailiwick of the same name, 23 miles S.S.W. of Ulm. It is situated on the small river Riss, and has 5000 inhabitants, chiefly engaged in bleaching, weaving, and tanning. The bailiwick contains one city, four market-towns, 36 villages, and 26,224 inhabitants.

BIBIENA, FERDINANDO GALLI, a painter and architect, was born at Bologna in 1657, and surnamed *Bibiena* from a territory of that name in Tuscany, in which his father was born. He acquired such reputation by his skill in architecture, that he was invited to the court of the Duke of Parma, and made his first painter and architect. Bibiena afterwards went to the emperor's court, where he had the same honours conferred upon him. He wrote two books on architecture; and died at Bologna in 1745. (Lanzi, *Stor. Pitt.*)

BIBLE,

IN Greek, *βιβλος*, or *ἡ βιβλος*, *the book*,—a name applied by Christians since the fifth century to denote the collective volume of the Sacred Writings, which are designated also by various other appellations, as the Holy Scriptures, Inspired Writings, Holy Writ, &c. The names Scripture or Writing (2 Pet. i. 20), Scriptures (Matt. xxii. 29; Acts viii. 24), Holy Scriptures (2 Tim. iii. 15), are those generally employed in the New Testament to denote the writings of the Old, which was styled by the Jews *mikra*, i.e. *lesson*, *lecture*, or *reading*.

Division of the Bible.

The Bible is divided into the Old and New Testaments, so termed because they contain the history of the revelations which Jehovah has made to mankind, and of his dealings with them, under two dispensations or covenants. The former was written in Hebrew, with the exception of a small portion, which is Chaldee, and refers to Babylon, where that language was spoken, and where the Jews were held in captivity for seventy years. The Old Testament is divided into the Law, the Prophets, and Writings. This division, which is referred to in the New Testament (Luke xxiv. 44) under the terms, the Law, the Prophets, and the Psalms, is believed to be as ancient as the formation of the canon. It is mentioned in the prologue of Jesus the son of Sirach, and in Philo, and in the Talmud, as well as in the New Testament. The prophets were divided by the ancient Jews into the *early* prophets, containing Joshua, Judges, Samuel, and Kings; and the *later* prophets, which were again subdivided into the *greater*, including Isaiah, Jeremiah, Ezekiel,—and

Bible.

the *lesser*, comprehending the remaining twelve. The third division, called by the Greeks "Hagiographa," or "Holy Writings," contains all the other canonical books not included in the preceding parts. The Talmud and the modern Jews divide the sacred books into eight prophets and nine hagiographa.

Josephus enumerates twenty-two books, five of Moses, thirteen prophets, and four books of morality.[1] This number is also mentioned by Origen and Jerome, but it does not seem to have been employed by the Jews themselves. According to the oldest catalogue extant in the Christian church, the Old Testament consists of the five books of Moses, viz., Genesis, Exodus, Leviticus, Numbers, and Deuteronomy; Joshua, Judges, and Ruth; four books of Kings and two of Chronicles; the Psalms of David; the Proverbs of Solomon, Ecclesiastes, Canticles, and Job; the prophets Isaiah and Jeremiah; the twelve prophets; the books of Daniel, Ezekiel, and Ezra, under which head Nehemiah and Ezra seem to be included.[2]

Order in which the books are arranged.

With regard to the order in which the different books were arranged, the Jews not only differed from the Christians, but they were not agreed among themselves. The Talmudists arranged the prophets thus: Joshua, Judges, Samuel, Kings, Jeremiah, Ezekiel, Isaiah, and the twelve minor prophets. The hagiographa they placed in this manner: Ruth, Psalms, Job, Proverbs, Ecclesiastes, Canticles, Lamentations, Daniel, Esther, Ezra, Chronicles. The Masoretic arrangement which is adopted in our modern Hebrew Bibles is as follows: The five books of Moses, Joshua, Judges, two books of Samuel, two books of Kings, Isaiah, Jeremiah, and Ezekiel, the twelve minor prophets, Psalms, Proverbs, Job, Canticles, Ecclesiastes, Esther, Daniel, Ezra, Nehemiah, and First and Second Chronicles. Luther's arrangement, which is made entirely according to his own judgment, has been adopted by our English translators, and is generally followed by Protestants.

Division of the text.

The Hebrew text is divided into smaller and larger sections, which have descended from a very remote antiquity. The sections called "parashes," or paragraphs, of which the Pentateuch contains 669, are of earlier origin than the Talmud, and probably belong to the time when the sacred books were first read in public. These divisions are of two kinds, called by the Jews "open," and "closed." The former are so called because they commenced a new line: the latter are called "shut" or "closed," because they were separated within the line by a space or break. It is supposed that the original purpose of the open sections was to denote the introduction of a new object, while the close sections were intended to point out the most natural and prominent paragraphs in the open ones, such as the change of speakers, the members of a genealogy, &c. The larger or ecclesiastical sections are believed to be of later origin than the smaller sections. They originated in the custom of reading every Sabbath in the synagogue a portion of the law. According to Maimonides, it was the received usage among the Jews to complete in this way the reading of the law in the space of one year, beginning with the Sabbath following the Feast of Tabernacles. Hence there are fifty-four of these divisions in the Pentateuch, corresponding to the Sabbaths in a Jewish intercalary year. At a later period, certain portions of the prophets were selected for public reading in the synagogue; they were termed, "Haphtaroth," and were written on separate rolls from the Pentateuch sections. The division of the Old Testament into chapters, as they still stand in the English version, is of Christian origin, and has been ascribed by Bale, bishop of Ossory, the celebrated antiquarian, to Stephen Langton, archbishop of Canterbury, who died in A.D. 1227, and by others to Cardinal Hugo de Sancto Caro, who flourished about the middle of the same century. This arrangement was made for convenience of reference, in a concordance for the Latin Bible which was constructed at this time. But the subdivision of the chapters into verses had not yet been introduced, and for the purpose of referring more easily to a particular sentence, Hugo placed the first seven letters of the alphabet along the margin of each page. From the Christians this capitular division was borrowed by the Jews, and transferred to the Hebrew Bible. Rabbi Isaac Nathan made use of it in the preparation of a Hebrew concordance in 1438; and it was first inserted in the printed Hebrew text by Daniel Bomberg in his edition of 1525. The numbering of the verses was first employed in the Hebrew Psalter printed by Henry Stephens in 1509. In the Latin translation of the Bible made by Sanctus Pagninus of Lucca, and published at Lyons in 1528, there is a division throughout into verses, marked with Arabic numerals on the margin. The system of Pagninus was adopted by Robert Stephens in the New Testament in 1551, and in the whole Bible in 1555; after this time the practice of numbering the verses became general.

Bible.

History of the text.

The sacred books of the Old Testament have come down to our times in MSS., the oldest of which date from the twelfth century. Nothing is known of the history of the text previous to that period after the return of the Jews from their captivity, when the canon was closed, and the separate books were formed into a completed whole. It is probable that the other sacred books, as well as the law, were preserved in or by the side of the ark of the covenant, and the well-known veneration of the Jews for their holy writings would lead them to watch carefully over the integrity of the text, although it has been exposed to the ordinary causes which deteriorate writings, and various errors have crept into it through the mistakes of transcribers. The existence of the Samaritan Pentateuch, however, whatever value may be attached to its peculiar readings, proves that the copy which we now possess of the five books of Moses is substantially identical with the original manuscript of the Jewish lawgiver. Various conflicting opinions have been entertained respecting the antiquity of the Samaritan copy of the Pentateuch, and the source from which it was derived. Usher maintained that it was the production of an impostor named Dositheus, who compiled this copy from the Hebrew and the Septuagint, a hypothesis which is manifestly untenable. Le Clerc and others have conjectured that the Israelitish priest who was sent by the king of Assyria to instruct the new inhabitants in the religion of the country,[3] took with him a copy of the law, which became thenceforward the Samaritan Pentateuch. But this opinion is not supported by any historical testimony. It has been supposed by Hottinger, Prideaux, and others, that the origin of the Samaritan Pentateuch is contemporary with the erection of the Samaritan temple on Mount Gerizim, in the time of Ezra, and that Manasseh, the Jewish priest who went over to the Samaritans, took with him a copy of the law. Dr Davidson contends that the Israelites obtained a copy of the Pentateuch in the reign of Josiah, who carried his reforms not only throughout Judah, but Israel also; for we are informed that he broke down the altars and high places, and the images in Samaria, in the cities of Manasseh, Ephraim, Simeon, and Naphtali. In consequence of these vigorous measures, the Israelites, *i.e.* the Samaritans, served the Lord, and even sent money for the repair of the temple at Jerusalem.[4] And when Josiah proclaimed a solemn passover at Jerusalem, the Israelites attended as well as the people of Judah, and heard the king read in the ears of his assembled people the words of the book of the covenant.[5] This conduct, however, indicates a previous knowledge of the law on the part of

Samaritan Pentateuch.

the Israelites, otherwise the urgent appeal of Josiah could scarcely have produced so powerful and wide an impression. Some are therefore of opinion with Morin, Kennicot, Michaelis, Stuart, and other eminent commentators, that copies of the Pentateuch must have been in the hands of the ten tribes from the time of Rehoboam. "The prophets, who frequently inveigh against the Israelites for their idolatry and their crimes, never accuse them of being destitute of the law or ignorant of its contents. It is wholly improbable, too, that the people when carried captive into Assyria took with them all the copies of the law. Thus we are brought to the conclusion that the Samaritan as well as the Jewish copy originally flowed from the autograph of Moses. The two constitute, in fact, different recensions of the same work, and coalesce in point of antiquity."[1]

Formation of the Old Testament canon.

With regard to the formation and completion of the Old Testament canon, a very steadfast tradition of the Jews affirms that the collection of the sacred writings began with Moses, was carried on by the prophets, and was completed in the time of Ezra and Nehemiah, under the auspices of those writers and of the men of the Great Synagogue,—"a number of elders, amounting to one hundred and twenty, who, succeeding to others in a continued series from the return of the Jews again into Judæa, after the Babylonish captivity, to the time of Simon the Just, laboured in the restoring of the Jewish church and state in that country. In order thereto, the Holy Scriptures being the rule they were to go by, their chief care was to make a true collection of those Scriptures and publish them to the people."[2] The first part of this tradition is confirmed by the testimony of the Holy Scriptures themselves. We are told (Deut. xxxi. 9) that when Moses had finished the writing of the law, "he delivered it to the priests the sons of Levi,[3] and unto the elders of Israel." And the king was enjoined to "write him a copy of this law in a book, out of that which is before the priests the Levites" (xvii. 18). From Deut. xxxi. 26, we still further learn that this copy of the law was deposited in the side of the ark of the covenant. We are informed that Joshua, following the example of Moses, wrote in the book of the law of the Lord the history which bears his name (Josh. xxiv. 26); and this, as Havernick remarks, evidently refers to the passage in Deuteronomy, and hence must be understood as intimating that this document also found a place in the side of the ark of the covenant. Le Clerc conjectures with great probability that the membrane on which the words of Joshua were written was agglutinated to the volume of Moses, which had been deposited in the side of the ark. In later times also we find traces of this same custom. Thus Samuel, when he had told the people the manner (law, *jus publicum*) of the kingdom, "wrote it in *the book*, and laid it up before the Lord,"—language which plainly intimates that the documents of Samuel were appended to some particular well-known book. At a later period, in the reign of Josiah, Hilkiah the high priest is said "to have found the book of the law in the house of the Lord" (2 Kings xxii. 8), doubtless in its appointed place of deposit—the side of the ark. Isaiah, in calling attention to his own prophecies, says, "Seek ye out of the book of the Lord and read, no one of these shall fail" (xxxiv. 16); a passage on which Gesenius remarks, "the poet seems to contemplate the placing of his oracle in a collection of oracles and holy writings, from which posterity might judge of the correctness of his prediction."[4] From these statements we are warranted to conclude that the books of the Old Testament which were successively sanctioned by Moses and the prophets, were acknowledged by the Jews before the exile as of divine authority; and that an authentic copy of each book, as soon as it was concluded, was laid up in the sanctuary, and placed under the care of the priests. As Abarbanel justly remarks on Deut. xxxi. 26, "God deposited there (in the side of the ark), the book of the law, to remain there as a true and abiding witness; and that no one might have the power of falsifying or disfiguring it. None could injure writings deposited among the genealogies and with the priests." This opinion respecting the formation of the canon is corroborated by the unvarying tradition of the Jewish rabbins from the earliest period. Thus, in one of the oldest portions of the Talmud, it is said, "Moses received the law at Sinai, and transmitted it to Joshua; Joshua to the elders; the elders to the prophets; the prophets to the men of the Great Synagogue."[5] Again, in the Babylonian Gemara the rabbins enlarge at considerable length on the canon. "The wise men," they state, "have left to us the law, the prophets, and the hagiographa, combined into one whole." "Who," they go on to say, "has written these books?" To this it is replied, *Moses* wrote the Pentateuch and Job; *Joshua*, the book which bears his name, and eight verses of Deuteronomy; *Samuel*, the books of Samuel, Judges, and Ruth; *David*, the Psalms, assisted by ten men; *Jeremiah*, his book, Lamentations, and the books of Kings; *Hezekiah and his College*, Isaiah, Proverbs, Canticles, Ecclesiastes; the *men of the Great Synagogue*, Ezekiel, Daniel, and Esther; *Ezra*, his book and the genealogies in the Chronicles; and *Nehemiah* finished the Chronicles,—a passage which, as Havernick has shown, refers, not to the composition of these books, but to their insertion in the canon.

Bible.

Completion of the canon.

With regard to the time when the sacred canon was completed, Hengstenberg, Havernick, and Stuart are of opinion that this event took place under Ezra, Nehemiah, and the Great Synagogue. In support of this view, they adduce the testimony of the son of Sirach, who cites the three divisions of the canon, and refers to it as a completed whole; and of Josephus who divides the Old Testament into twenty-two books "which were justly esteemed divine," and affirms that from the time of Artaxerxes down to his own day, no one had dared either to add to, or to take from, or to alter anything in the sacred books. It was not every one, he says, who was permitted among the Jews to write therein; only the prophets were competent, in virtue of their divine inspiration. The thirteen prophets wrote their history from the death of Moses to the reign of Artaxerxes. From Artaxerxes to our day, everything also has been recorded in books, but these have not been regarded as deserving equal credit with the former, because of the failure of the exact succession of the prophets."[6] It is also contended by these writers that the time of Ezra and Nehemiah was the most suitable period for such an undertaking: that, moreover, it was the latest period at which the canon could be fixed. "As the duty to be performed was not merely that of determining the genuineness of certain books, but of pointing out those which had been divinely ordained as a rule of faith and morals to the church, it was one which none but a prophet could discharge." Now, in the days of Nehemiah and Ezra there were several prophets living, among whom we know the names of Haggai, Zechariah, and Malachi; but with that age expired the line of prophets whom God had appointed "to comfort Jacob and deliver them by assured hope." As the men of the Great Synagogue were thus the last of the prophets, if the canon was not fixed by them the time was past when it could be fixed at all. Lastly, it is urged, that we find in the time of Ezra and Nehemiah the canon treated as a whole, and regarded with the utmost veneration; that all subse-

quent references to the sacred writings presuppose the existence of the complete canon; and that of no one among the apocryphal books is it so much as hinted, either by the author or by any other Jewish writer, that it was worthy of a place among the sacred books, though of some of them the pretensions are in other respects sufficiently high.[1] On the other hand, Dr Davidson adduces the opinion of the later Jews, who affirm that the canon was closed by Simon the Just, who died 202 B.C. He contends that some books were received into the Jewish canon after the time of Ezra and Nehemiah; and therefore concludes that the important work begun by these eminent reformers was continued after them by the most competent authority, till the entire collection was declared complete, about 200 B.C.[2]

Canonical books of the Old Testament.

The Old Testament canon, as established in the time of Ezra, has remained unaltered to the present day. The following are the canonical books of the ancient economy, arranged in the order in which they are supposed to have been published, with the number of chapters in each:—

	Number of Chapters.		Number of Chapters.
Genesis	50	Ecclesiastes	12
Exodus	40	Song of Solomon	8
Leviticus	27	Isaiah	66
Numbers	36	Jeremiah	52
Deuteronomy	34	Lamentations	5
Joshua	24	Ezekiel	48
Judges	21	Daniel	12
Ruth	4	Hosea	14
1 Samuel	31	Joel	3
2 Samuel	24	Amos	9
1 Kings	22	Obadiah	1
2 Kings	25	Jonah	4
1 Chronicles	29	Micah	7
2 Chronicles	36	Nahum	3
Ezra	10	Habakkuk	3
Nehemiah	13	Zephaniah	3
Esther	10	Haggai	2
Job (date uncertain)	42	Zechariah	14
Psalms	150	Malachi	4
Proverbs	31		

The Old Testament contains in all, 39 books, 929 chapters, 23,214 verses, and 592,439 words.

Great care was taken by the Jews to preserve the accuracy of the sacred text, and from an early period they were in the habit of numbering the verses and words, and even letters, marking the sum-total at the end of each separate book and section,—a practice which, though in itself laborious and trifling, had a good effect on the purity of the text. The watchful care of Almighty God over the sacred books containing His revealed will, is strikingly manifested in the manner in which they have been preserved through the instrumentality of the Jews. "The reverent attention which this people gave to the Hebrew text, and the jealousy with which they guarded it from corruption, must have belonged to the wise arrangements of the Highest, who puts it into the heart of men to engage in works tending to promote his own glory." Very soon after its invention the Jews took advantage of that new and beautiful art which in the middle of the fifteenth century superseded the labours of the calligraphists; and copies of the Hebrew Scriptures were among the earliest printed books. So early as 1477 the Psalter was printed, probably at Bologna, with the commentary of Kimchi interspersed among the text. The Pentateuch was printed at the same place in 1482, with the Targum of Onkelos, and the commentary of Solomon Jarchi. Ruth, Lamentations, Ecclesiastes, and Esther, appeared the same year. A few years later appeared the *former* prophets, viz., Joshua, Judges, Samuel, and Kings, with Kimchi's commentary; and these were soon after followed by the *later* prophets, viz., Isaiah, Jeremiah, Ezekiel, and the twelve minor prophets. The Hagiographa first appeared at Naples in 1487. The entire Hebrew Bible was first printed at Soncino in 1488; another edition, which has neither date nor place, is also supposed to have appeared at Soncino. The third complete edition is that of Brescia in 1494; it was edited by Rabbi Gerson, and was the edition which Luther used in making his German version. The first edition of the Hebrew Scriptures published under the auspices of Christians was the Complutensian Polyglot, prepared at the expense of Cardinal Ximenes. It was completed in the year 1517, but did not appear till 1522, at Alcala, in Spain. Daniel Bomberg's first edition of his Rabbinical Bible, in four vols. folio, was published at Venice in 1518. His second edition, which was followed by several others, is the parent of our present Hebrew Bibles. The Antwerp Polyglot (1569), in eight vols. folio, contains the Complutensian text, collated with Bomberg's; and Hutter's edition (1587), presents a mixed text taken from the Antwerp, Paris, and Venetian editions. Other accurate editions were published by Buxtorf (1611 and 1618), by Moses Ben Simeon of Frankfort (the Amsterdam edition 1724), and by Athias (1661 and 1667), with a preface by Leusden. The second edition of Athias formed the basis of Van der Hooght's, published in 1705, and which may be regarded as the *textus receptus*. The elaborate editions of Kennicot, and De Rossi, contain an immense collection of various readings, as do also the editions of Munster, Michaelis, Houbigant, Jahn, and the polyglots.

Editions of the Hebrew Bible.

The New Testament.

The New Testament is written in what has been called Hellenistic or Hebraizing Greek, which is strongly tinged with a Hebrew colouring, derived partly from the country of the writers, partly from the original and peculiar ideas which they sought to convey to their readers. The language, idioms, and style of the sacred volume are all in accordance with the hypothesis that its authors were of Jewish extraction, and living at the commencement of the Christian era. There is abundant evidence in favour of the inspiration of the various books of the New Testament, but it is difficult to point out the precise period at which they were collected, and included in the sacred canon. The weight of authority is decidedly in favour of the opinion, that each of the original churches made a complete collection for itself of those writings which could be proved by sufficient evidence to be the production of inspired men, and that the general accordance of these various collections as to the books admitted, furnishes conclusive proof of the accuracy of the existing canon. The earliest reference to a collection of the New Testament Scriptures occurs in 2 Peter iii. 16, where the writer speaks of the epistles of Paul in such a way as to indicate that all, or the greater part of them, had been collected together at that time, and were regarded by the churches generally as entitled to equal reverence with the other Scriptures,—viz., the sacred writings of the Old and the New Testament. Mention is made of the law, the prophets, the gospel, and the apostles, in the epistle to Diognetus—one of the earliest of the uninspired Christian writings. Ignatius classes the gospels and the apostles along with the prophets. Theophilus of Antioch frequently applies to the New Testament Scriptures the appellation of "the Holy Writings," and speaks of the law, the prophets, and the gospel, as alike divinely inspired; and Clement of Alexandria distinguishes them into the "gospels and apostolic discourses." About the beginning of the third century these two collections, viz., the gospels and the apostolic epistles had been put together under one name—the New Testament. Thus, Tertullian, in his treatise against Marcion, applies this desig-

Bible.

nation to the whole collection, which he distinguishes from the "ancient Scriptures;" and Irenæus repeatedly calls the books of the New Testament "the Holy Scriptures," "the oracles of God," and puts them on a level with the law and the prophets. These and other similar statements warrant the conclusion that before the middle of the third century the New Testament Scriptures were formed into one collection, designated by one general title, and regarded by Christians as possessed of divine authority. This conclusion is corroborated by the testimony of Origen and Eusebius, who made careful inquiry respecting this subject, and have left an accurate record of the books which were received as canonical by the church in their day. "Of the *ten* ancient catalogues of the New Testament books still extant, *six* accord exactly with our present canon, while of the rest *three* omit only the Apocalypse, and *one* omits with this the Epistle to the Hebrews. The identity of these books with the present canonical Scriptures is proved by the copious quotations from them contained in the writings of the early fathers. It is evident from these observations that the formation of the New Testament canon was *gradual*; the collection was not made by one man, one council, at one time, or in one place. The adherents of the Christian religion in different lands came to agree in the same conclusion *progressively*, by *tacit consent*. They did so *independently* to a great extent, and in countries remote from one another. They judged by internal evidence, by tradition, by the fact of the writers being apostles or apostolic men. . . . . Slowly and surely did they arrive at the entire separation of the sacred Scriptures from the spurious imitations which were then current. And in the result of their judgment modern scholars commonly acquiesce."[1]

Canonical books of the New Testament.

The following are the canonical books of the New Testament, arranged in the order in which they are given in our authorized version, with the number of chapters in each, and the time at which they are supposed to have been written:—

	Number of chapters.	Date. A.D.
Matthew	28	38
Mark	16	65
Luke	24	63
John	21	97
Acts	28	64
Romans	16	58
1 Corinthians	16	56
2 Corinthians	13	57
Galatians	6	52
Ephesians	6	61
Philippians	4	62
Colossians	4	62
1 Thessalonians	5	52
2 Thessalonians	3	52
1 Timothy	6	64
2 Timothy	4	65
Titus	3	64
Philemon	1	62
Hebrews	13	63
James	5	61
1 Peter	5	64
2 Peter	3	65
1 John	5	69
2 John	1	69
3 John	1	69
Jude	1	70
Revelation	22	96

Editions of the Greek Testament.

The first part of the Greek Testament that was printed consisted of the hymn of Zacharias and Mary, published at Venice in 1486, and the first six chapters of St John's Gospel, which appeared in 1504. The first printed edition of the Testament was that of the Complutensian Polyglot, which was published at the expense of the celebrated Cardinal Ximenes. The printing of the New Testament in this edition was commenced in 1502, and was completed in 1514, but the work was not published till 1522. Before this edition saw the light, Erasmus published his edition at Basle in 1516; and four other editions followed successively between 1519 and 1535. Several editions were published by Robert Stephens, the third of which is called the *Regia* or royal edition, and is elegantly printed. The fourth edition is remarkable as being the first into which the division of verses was introduced. The first Elzevir edition, so called from the name of the printer, appeared at Leyden in 1624. The second, which issued from the same press in 1633, is the best of all the Elzevir editions, and has long formed the "received text." Other celebrated editions are those of Beza; the London Polyglot, edited by the learned Walton; Mill's critical edition (1707), which was the labour of thirty years; the splendid edition of John James Wetstein, which appeared in 1751; that of Griesbach, published in 1775–77, which has been said to have ushered in the "golden age" of criticism; the antagonistic edition of Professor Scholz, an eminent Roman Catholic critic, which appeared in 1830-35; and the recent editions of Tischendorf and Lachmann.

Bible.

State of the text.

The text of the New Testament has of course suffered from the mistakes of translators and from other obvious causes, but it is confessedly free from "gross and palpable errors." The researches of modern critics have conclusively shown that it has been preserved with great care, and does not materially differ from what it was 1700 years ago. The various readings which have arisen from the commutation of letters, the transposition of words, abbreviations, seeing and hearing incorrectly, and other causes, amounted in Mill's edition to 30,000, and have now increased to upwards of 100,000. This circumstance was at one time eagerly laid hold of by infidels, and excited no small alarm among religious men. But all apprehension on this point has long ago been removed, and it is now generally admitted that the greater part of these variations in the text of the Scriptures are not of the slightest importance as regards either the history or the doctrines of our religion. "Of the various readings of the New Testament," says Mr Norton, "nineteen out of twenty, at least, are to be dismissed at once from consideration, not on account of their intrinsic unimportance—that is a separate consideration—but because they are found in so few authorities, and their origin is so easily explained, that no critic would regard them as having any claim to be inserted in the text. Of those which remain, a very great majority are entirely unimportant. They consist in different modes of spelling; in different tenses of the same verb, or different cases of the same noun, not affecting the essential meaning; in the use of the singular for the plural, or the plural for the singular, where one or the other expression is equally suitable; in the insertion or omission of particles such as ἀν and δε, not affecting the sense, or of the article in cases equally unimportant; in the introduction of a proper name where, if not inserted, the personal pronoun is to be understood, or of some other word or words expressive of a sense which would be distinctly implied without them; in the addition of 'Jesus' to Christ, or 'Christ' to Jesus; in the substitution of one synonymous or equivalent term for another; in the transposition of words, leaving their signification the same; in the use of an uncompounded verb, or of the same verb compounded with a preposition—the latter differing from the former only in a shade of meaning. Such various readings, and others equally unimportant, compose far the greater part of all, concerning which there may be or has been a question whether they are to be admitted into the text or not, and it is therefore obviously of no consequence in which way the question has been or may be determined."[2]

Various readings.

The Septuagint.

The oldest version of the Old Testament in any language is the Greek translation, commonly called the SEPTUAGINT, either because it was approved and sanctioned by the Jewish sanhedrim, which consisted of seventy or seventy-two persons, or more probably from the Jewish fable that so many individuals were employed in the work. The history of this version is exceedingly obscure, and it is difficult to discriminate the genuine from the spurious traditions which are current respecting its origin. The earliest historical notice of the Septuagint is to be found in the writings of Aristobulus, a Jew, who lived about the commencement of the second century before Christ. He states that "the entire interpretation of the law was made in the time of a king

[2] Norton's *Genuineness of the Gospels*, vol. i. additional notes, pp. 38, 39.

surnamed Philadelphus, ... Demetrius Phalereus being actively employed about it." To this statement it has been objected, that Demetrius Phalereus is represented as living in the reign of Ptolemy Philadelphus, whereas he lived under his predecessor Ptolemy Lagus, and died soon after his death. This was undoubtedly the case; but it does not follow that the account of Aristobulus is therefore to be rejected as wholly undeserving of credit. Havernick contends that Aristobulus intended merely to say that Demetrius was the person who took an active part in the translation, or caused it to be undertaken, the whole being finished in the time of Philadelphus. Others are of opinion that Aristobulus made a mistake in the name of the king. Hody harmonizes the discrepancy by placing the translation of the Pentateuch in the two years during which father and son reigned conjointly, 286 and 285 B.C. An equivocal statement in the prologue of Jesus the son of Sirach has been supposed to intimate that "the law and the prophets and the rest of the books" were translated into Greek at the time he wrote; but it cannot be proved that the passage has any reference to the Septuagint. A minute account of the origin of this version has been given by Aristeas, an author who pretends to be a Gentile and a favourite at the court of Ptolemy Philadelpus, king of Egypt. In a letter addressed to his brother Philocrates, he relates that Philadelphus, when founding a public library at Alexandria at a great expense, was advised by Demetrius Phalereus to apply to the Jewish high priest Eleazar for a copy of the book containing the Jewish laws. As a preliminary step, he purchased the freedom of all the Jews in his dominions who had been taken captive by his father or himself. He then sent Aristeas and Andreas with costly presents and a letter to Eleazar, requesting him to send to Alexandria seventy-two interpreters. They were accordingly despatched with a copy of the law, "consisting of different parchments, in which the law was written in gold in the Jewish letters;" and were received and entertained by the king for several days with great respect and liberality. Demetrius then conducted them to an island, which appears to have been Pharos, where they were lodged together in a splendid house near the shore. The translation was completed in seventy-two days, having been written down piece by piece by Demetrius, as agreed upon after mutual consultation. It was then publicly read by him to a number of the principal Jews whom he had summoned together for that purpose. They approved of the translation, and imprecations were pronounced against any one who should presume to alter it. The Jews requested permission to take a copy for their own use; and the work was carefully preserved by command of the king, who sent home the interpreters loaded with presents. The substance of this narrative is repeated by Josephus; but the greater part of it is undoubtedly fabulous, and many glaring falsehoods were afterwards added to it in the days of Justin Martyr and Epiphanius, which were received by these credulous men without hesitation. The interpreters were said to have been shut up in separate cells, where, without any communication with one another, they composed seventy-two distinct versions, miraculously agreeing in every particular. Hence it was concluded that they were inspired, and their version was received as infallibly correct. This absurd story was believed both by the early Jewish rabbins and by most of the Fathers, and its credibility was not called in question till the latter half of the seventeenth century. It has now been proved to contain particulars improbable, incredible, and contrary to history. But there is good reason to believe that it is not wholly fictitious. Dr Davidson has shown that truth lies at the basis of the story contained in the narrative of Aristeas[1], and that in all probability the version was really made at the command of an Egyptian king; but that king was Ptolemy Lagus, not Philadelphus,—whether from a religious, a political, or a literary motive, it is impossible to say. When the version was made by royal authority, it is quite probable that the translators may have thought of the ecclesiastical purpose which it would serve, and that it fell in with their religious desires and wants, though they would not have undertaken it without an external impulse.

There can be no doubt that the version of the Septuagint was made by degrees, and that the Pentateuch was translated first. The precise time at which the separate portions of the version were made cannot now be ascertained; but it is probable that the interval between the translating of the law and the prophets was very short, and that the entire work was completed before the thirty-eighth year of Ptolemy Physcon. The version itself affords internal evidence that various hands were employed upon it; but nothing certain can be known respecting the number of translators. The tradition that there were seventy-two must be rejected as fabulous; but there must have been at least five or six individuals engaged on the entire work, which is consequently of unequal value. The translator of the Pentateuch was unquestionably the most skilful of all the interpreters; and that portion of the work far surpasses the others in fidelity and accuracy. Next to it in point of excellence is the version of the Proverbs. The Psalms and prophets have been but indifferently executed. The translation of Isaiah is exceedingly defective, and that of Daniel is the worst of the whole. It was probably on this account that the version of Theodotion was very early substituted for it by the Greek Church.

The well-known fact that the Septuagint harmonizes with the Samaritan Pentateuch in more than a thousand places where they differ from the Hebrew text, has given rise to various hypotheses to account for the agreement. Selden, Hottinger, Hassenchamp, and Eichorn have supposed that the version of the Pentateuch was made from the Samaritan text rather than the Hebrew; others, that the one was interpolated from the other; but the irreconcileable enmity which subsisted between the Jews and the Samaritans, both in Egypt and Palestine, renders both of these conjectures in the highest degree improbable. Dr S. Lee accounts for the agreement by supposing that the early Christians interspersed their copies with Samaritan glosses, which ignorant transcribers afterwards inserted in the text.[2] But, to say nothing of the reverence with which the early Christians regarded their sacred books, there is no evidence that they were acquainted with the Samaritan Pentateuch and its glosses. A much more plausible hypothesis has been proposed by Gesenius, viz., that the Samaritan Pentateuch and Septuagint version both flowed from a common recension of the Hebrew Scriptures, one older than either, and different in many places from the recension of the Masorites now in common use. Professor Stuart, by whom this supposition has been adopted, thinks that it will account both for the differences and for the agreements of the Septuagint and Samaritan versions; but other writers are of opinion that no satisfactory solution of the problem has yet been offered.

The Septuagint version is free rather than literal; and the translators have frequently mistaken the meaning of the original, and have indulged in many liberties with regard to the text. Its merits, however, are unquestionably great, and it has rendered important service not only in the criticism but also in the exposition of the Old Testament. It speedily acquired a high reputation among the Hellenistic Jews; and it was read publicly in the synagogues, not only of Egypt, but, sometimes at least, of Palestine itself. Josephus, though he was acquainted with Hebrew, made more

Bible. use of the Greek version than of the original itself, and it was universally received by the early Christians. But the feelings of the Jews speedily underwent a change. In the controversies between them and the Christians, the latter were in the habit of appealing to the prophecies which this version contained respecting the Messiah, and which were fulfilled in Jesus of Nazareth. The Jews, now worsted in argument, began to deny that the Septuagint agreed with the Hebrew original; and ultimately this version became so odious to them, that, according to the Talmud, a fast was appointed on the 8th day of the month Thebet, the day on which the law was translated into Greek, to perpetuate the remembrance of this inauspicious event. It was owing to this feeling that the Jews had recourse to the version of Aquila, who is supposed to have undertaken a new translation from the Hebrew for the express purpose of supplanting the Septuagint.

Other Greek versions.

AQUILA was a Jewish proselyte, a native of Pontus, who undertook a translation of the Old Testament into Greek, probably about the middle of the second century of the Christian era. It appears from Jerome that there were two editions of this version, the second of which was more literal than the first; but it is impossible to determine whether it embraced the whole of the Old Testament or not. The version of Aquila was highly prized by the Jews, who called it the Hebrew verity, and probably this very circumstance tended to excite a prejudice against it among the Fathers, who accused him of perverting some prophecies relating to the Messiah. The translation adheres so closely to the original as to be in some cases unintelligible.

The second who composed a Greek version of the Scriptures was THEODOTION, who, according to Irenæus, was a native of Ephesus, and a Jewish proselyte. Jerome and Eusebius call him an Ebionite, or semi-Christian. He must have lived before A.D. 176. Only a few fragments of the work remain, but, according to the testimony of those who had the opportunity of examining it, the translation followed the Septuagint so closely, that it has been supposed that his intention was to make a revision of its text, rather than a new version. The numerous errors into which he has fallen, show that his knowledge of the original was not extensive or accurate.

The third Greek version was made by SYMMACHUS, who like Theodotion, appears to have been an Ebionite, and is said to have been a Samaritan by birth. The remaining fragments of the work show that the style is good, and the diction perspicuous and intelligible. The ancient writers who speak of this version remark that the author translated freely, and gave the sense of the original rather than the words. As this translation was not known to Irenæus, it is believed to be of later date than those of Aquila and Theodotion.

Three other Greek versions of the Scriptures were discovered by Origen when he travelled into Eastern countries for the purpose of collecting materials for his polyglot. They did not extend to the entire Old Testament, but only to several books, and are usually denominated the fifth, sixth, and seventh, from the position which they occupied in the columns of Origen's work entitled the *Hexapla*. Their authors were unknown to Origen himself, but they are supposed to have been Jewish Christians. These anonymous translations must have been made subsequently to those of Aquila, Theodotion, and Symmachus; and judging from the scanty fragments of them which remain, their rendering of the original must have been somewhat free and paraphrastic.

Another ancient Greek version of several books of the Old Testament, which is deposited in St Mark's library at Venice, is supposed to have been made at Byzantium for private use, not earlier than the ninth century. It has been translated directly from the original, and is more literal than any other ancient version. It cannot be certainly known whether the author was a Jew or a Christian.

Bible. There is a version of the five books of Moses in the Samaritan dialect, made from the Samaritan copy of the Pentateuch, which it follows word for word. The author and the date of this translation are alike unknown, but Dr Davidson is of opinion that it was probably made either in the second or the third century.

Samaritan version.

Old Syriac version.

One of the oldest translations of the Bible made by Christians is the version commonly called the OLD SYRIAN or PESHITO, *i.e. the simple*, because it adheres to the literal meaning, in opposition to the allegorical translations and expositions. It was undoubtedly made at a very early period, but its precise age is involved in obscurity. The traditions of the Syrians themselves claim for the Peshito a very high antiquity; some of them even allege that it was made in the time of Solomon and Hiram, but no credit can be attached to such fabulous assumptions. Jacob of Edessa adopts the tradition that this version was made in the days of Thaddeus the Apostle, and the Edessenic king Abgarus; and Havernick is inclined to regard this account as entitled to credit. Michaelis assigns it to the first century of our era, while Dr Davidson is of opinion that it probably belongs to the second. The first author who mentions it is Ephraem Syrus, who died A.D. 376. In his time it had met with a general reception among the Syrian churches, and was employed by him as the basis of his commentaries on the Bible. The Peshito originally embraced only the canonical books of the Old Testament, but the Apocrypha must also have been translated into Syriac at a very early period, since they are cited by Ephraem Syrus, who, however, did not regard them as canonical books. With regard to the author of this version, some have contended that he was a Jew, but the weight of evidence decidedly preponderates in favour of a Christian origin. It has been made directly from the Hebrew, and adheres more faithfully to the original than any other of the ancient versions. The Old Syrian version of the New Testament wants the second and third Epistles of John, the second of Peter, that of Jude, and the Apocalypse. Some have accounted for this circumstance by supposing that the translator must have made his version either before these books were written, or at least before they were acknowledged in Syria as of divine authority; while others think the fact may be explained by the non-reception of these books in the district where the version was made.

Arabic and Persian translations.

Several versions of the Scriptures were made in the ARABIC language, but all of these are supposed to be later than the Mahometan era. Three of these translations were made directly from the Hebrew, others were derived from the Peshito, while several have proceeded from the Septuagint. A version of the Old Testament in the PERSIAN language seems to have existed at an early period, and is mentioned both by Chrysostom and Theodoret. But the Persian translation of the Pentateuch, printed in the London Polyglot, and which was made by a Jew, Rabbi Jacob, the son of Joseph Tawus, is undoubtedly of later origin than the eighth century. It was first printed at Constantinople in 1546. A version of the Bible in Persian was made a few years ago by the late Rev. Dr Glen, who was sent to Persia for that purpose by the Scottish United Presbyterian Church.

Egyptian versions.

The MEMPHITIC or COPTIC translation of the Bible, written in the dialect of Lower Egypt, was taken from the Septuagint, and belongs to the third century. The THEBAIC or SAHIDIC version, in the dialect of Upper Egypt, was also made from the Greek, probably about the same period.

Æthiopic version.

Chrysostom alludes to a version of the Scriptures which was in use among the Æthiopians in his day, and appears to have been made in the fourth century, during which Christianity was diffused among that people. This translation is written in the old sacred language called the Geez, and although made by Christians is likewise used by the Æthiopian Jews. It was unquestionably derived from the Septuagint, and embraces not only the whole of the canonical books of

Bible.

Scripture, but also the Apocrypha. The entire work is extant in Europe, but only detached portions of it have been printed.

Armenian, Georgian, Slavonic, and Gothic versions.

The ARMENIAN version of the Bible was made by Miesrob, the inventor of the Armenian alphabet, assisted by two of his pupils. It was taken from the Greek, and was completed in A.D. 410. The GEORGIAN version, which belongs to the sixth century; the SLAVONIC, which was made by Cyril of Thessalonica, and his brother Methodius who invented the Slavic alphabet; and the GOTHIC, which was translated by Ulphilas in the fourth century,—were all derived from the same source.

Latin versions.

There has been a LATIN version of the Bible from the first ages of the Christian Church; but it is now impossible to discover when and by whom it was made. In opposition to Jahn, Hug, and Van Ess, Eichorn is of opinion that there was only one distinct Latin translation, and that it was made in Africa in the course of the first century; but the first certain traces of this version, called the *Vetus* or old Latin, are found at the close of the second century. Some fragments of it still exist, which show it to have adhered literally to the κοινή, or the text of the Septuagint which existed before Origen's *Hexapla*, whose defects it preserves. In the year 382, Jerome, at the request of Pope Damasus, undertook to revise and correct this version, which had become exceedingly corrupt. He first corrected the Psalms, producing what is called the *Roman Psalter*, because it is used in the church of the Vatican. Subsequently, he undertook a second version of this part of the Scriptures, which bears the name of the *Gallican Psalter*, because it was subsequently adopted in the churches of Gaul. He afterwards revised in the same way the rest of the Old Testament, but the only portions of the work which have descended to our day are the two Psalters and the book of Job.

The Vulgate.

Jerome next, at the request of his friends, and for the purpose of assisting the Christians in their controversies with the Jews, undertook a new version from the Hebrew, between the years 385 and 405. Although not free from defects, principally caused by the haste with which some parts of the work were executed, it is undoubtedly the best translation of which antiquity can boast. But in spite of its great merits, it met with a very unfavourable reception in the Latin Church. The learned and laborious translator was denounced as a heretic, and the new version was declared to be a falsification of the Word of God. Its value, however, was recognised from the first by a few discriminating scholars, and it gradually won its way to public favour till it became the only received version, and this by tacit consent, in consequence of its intrinsic merits, for it obtained no official sanction until the Council of Trent.

In the course of time Jerome's version became exceedingly corrupt, both by a mixture of the old version, and by interpolations from liturgical books. In the ninth century (A.D. 802) a version of the text was undertaken by command of Charlemagne, who intrusted the task to the celebrated Alcuin. In the eleventh century a new version was undertaken by Lanfranc, archbishop of Canterbury, and another in the following century by Cardinal Nicolaus. After the twelfth century were begun what were termed *correctoria biblica*, in which the Latin text was furnished with marginal glosses from other MSS., the fathers, and other venerated teachers of the church. The Vulgate was the first book ever printed, and it issued from the press many times without date or place. The first that had a date was published at Mentz in 1462, and other editions quickly followed. The corruption of the text now became more apparent than ever, and the necessity of an attempt to correct its errors was acknowledged by the publication of the Complutensian Polyglot, and the critical editions of Isidore Clarius, Robert Stephens, Benoist, and others.

In the year 1546, the Council of Trent passed its famous decree respecting the Vulgate, ordaining that it "shall be used in public readings, disputations, sermons, and expositions, as authentic, and that none is to presume to reject it under any pretence whatever." The text of the Vulgate having become exceedingly corrupt, various attempts were made to revise and correct it. Two editions were issued under the sanction of the papal chair, termed respectively the Sixtine and Clementine Bibles, the variations between which amounted to above two thousand: the latter is the basis of all subsequent editions of the Vulgate, from those of Plantin, which appeared in 1599 and 1650, to that of Leander Van Ess, published by authority of Leo XII. in 1826.

Bible.

After the downfall of the Roman empire and the gradual disuse of the Latin tongue, the Holy Scriptures were translated into all the languages of modern Europe.

French versions.

The oldest FRENCH Bible is the version of Peter de Vaux, the leader of the Waldenses, who lived about the year 1160. Raoul de Presle also translated the Bible into French about the year 1380; and besides these there are several old French translations of particular portions of the Holy Scriptures. The doctors of Louvain published an edition of the Bible in French at Louvain, by order of the Emperor Charles V., in 1550. The version of De Sacy, which was published in 1692, with explanations of the literal and spiritual meaning of the text, was received with great applause, and has often been reprinted. With respect to the versions of the New Testament in French, one of the best known is that which F. Amelotte of the Oratory executed by the direction of some French prelates, and printed with annotations in 1666, 1667, and 1670. The Mons New Testament, printed in the year 1665, with the permission of the Archbishop of Cambray and the license of the king of Spain, was condemned by Pope Clement IX. in 1668, and by Pope Innocent XI. in 1679, and in several bishoprics of France at different times. The New Testament published at Trevoux in 1702 by M. Simon, with literal and critical annotations upon difficult passages, was condemned by the bishops of Paris and Meaux in 1702. Another translation of the New Testament was published in 1697 by Bouhours a Jesuit, with the assistance of Michael Tellier and Peter Bernier, who were likewise Jesuits. This version, however, follows so closely the Latin text from which it is translated that it is for the most part harsh and obscure. The most approved French translations of the Scriptures are those of Descarrières and De Vence. There are also several French versions of the Bible published by Protestants. The version of Olivetan, printed at Neufchâtel in 1535, has been frequently reprinted with the corrections of Calvin and others. A somewhat paraphrastic version was published at Geneva in 1644 by John Diodati. A translation of the New Testament executed by J. Faber Stapulensis was revised and accommodated to the use of the Reformed churches in Piedmont in 1534. Lastly, a version of the New Testament in French was published at Amsterdam in 1703 by Le Clerc, with annotations taken chiefly from Grotius and Hammond; but this version was prohibited in Holland by order of the States-General, as tending to revive the errors of Sabellius and Socinus.

Italian versions.

The earliest ITALIAN Bible published by the Roman Catholics is the version of Nicolas Malermi, a Benedictine monk, printed at Venice in 1471. It was made from the Vulgate. The translation of Anthony Braccioli, published at Venice in 1532, was prohibited by the Council of Trent. Martini's translation is now commonly used in Italy. The Protestants also have their Italian Bibles. There is the version of Maximus Theophilus, published in 1551; and another of John Diodati, published in 1607 and 1641. The Jews in Italy have no entire version of the Bible in Italian; the inquisition having constantly refused to allow them the liberty to print one.

Spanish versions.

The earliest SPANISH Bible of which we have any notice is one printed at Valencia in 1478. The Gospels and Epistles were published in that language by Ambrose de

Bible. Montesin in 1512; the whole Bible by Cassiodore de Reyna, a Calvinist, in 1569; and the New Testament by Francis Enzinas or Driander in 1543. An ancient version of the Bible for the use of the Spanish Jews was printed in Gothic characters at Ferrara in 1553.

German versions. The most ancient translation of the Bible in the GERMAN language is that of Ulphilas, bishop of the Goths, about the year 360. This version did not contain the books of Kings, which the bishop omitted, lest the wars mentioned therein should encourage the martial spirit of the people. An imperfect manuscript of this translation was found in the abbey of Verden, near Cologne, written in letters of silver, for which reason it is called *Codex Argenteus*. It was published by Francis Junius in 1665. The oldest German Bible extant is that of Nuremberg (1446), which was translated from the Vulgate by an unknown author. A translation of the Bible into German by John Eckius, was published in 1537, along with the version of the New Testament by Emzer, chaplain to George, Duke of Saxony. Another version by Ulembergius of Westphalia, procured by Ferdinand, Duke of Bavaria, was printed in 1630. But by far the most important version of the Scriptures in the German language was made by the great reformer Martin Luther, who spent eleven years in completing it. The New Testament was published in 1522, the Pentateuch in 1523, the historical books and the Psalms in 1524, the books of Solomon in 1527, Isaiah in 1529, the prophets in 1531, and the other books in 1530. This celebrated translation is clear and accurate, and the language pure and idiomatic. It has exercised a powerful influence on the language and literature of Germany.

Belgian or Flemish versions. The FLEMISH Bibles of the Romanists are very numerous. For the most part they have no author's name prefixed to them, till the version of Nicolas Vinck, which was printed at Louvain in 1548. Till the year 1637 the Flemish versions used by the Protestants were taken principally from the translation of Luther. In 1618 the synod of Dort appointed a new translation to be made of the Bible into Flemish, but the work was not finished till 1637.

Danish versions. The first DANISH Bible was published in 1550 by Peter Palladius, Olaus Chrysostom, John Syningius, and John Maccabæus, who followed the first German version of Luther. Another translation was made by John Paul Resenius, bishop of Zealand, in 1605; and a version of the New Testament by John Michel, in 1524.

Swedish version. In 1534 Olaus and Laurence published a SWEDISH Bible from the version of Luther; it was revised in 1617 by order of King Gustavus Adolphus, and was afterwards almost universally adopted.

Bohemian, Polish, Russian, and Sclavonian versions. The Bible was printed in the BOHEMIAN language at Prague in 1488, and another version made by eight Bohemian doctors, who were sent to the schools of Wirtemburg and Basle to study the original languages, was printed in Moravia in the year 1539. The first POLISH version of the Bible, it is said, was that composed by Hadewich, wife of Jagellon, Duke of Lithuania, who embraced Christianity in 1390. A Polish translation of the Bible made by several Roman Catholic divines, and especially by James Wieck, a Jesuit, was published at Cracow in 1561. A translation made by the Polish Protestants from Luther's version, was published in 1596 and dedicated to Uladislaus IV., king of Poland. A version in the RUSSIAN language, made from the Greek by St Cyril, the apostle of the Sclavonians, was published in 1581; but, in consequence of its obscurity, Ernest Gluck, who had been carried prisoner to Moscow after the taking of Narva, undertook a new translation of the Bible into modern Russian, which was printed at Amsterdam in 1698.

English versions. Various portions of the Bible were rendered into SAXON between A.D. 706 and 995 by Adelm, bishop of Sherbourn, Egbert, bishop of Lindisferne, the Venerable Bede, and other translators. The first ENGLISH version of the Bible known to be extant is that mentioned by Usher as supposed to have been made in 1290. Three MS. copies of it are still in existence. The next translation of the sacred Scriptures into English was made by the celebrated reformer Wickliffe about the year 1380. A complete copy of this work has recently been published for the first time. Bible.

Tyndale's Bible. The first *printed* Bible in our language was translated by William Tyndale. His version of the New Testament was printed at Antwerp in 1526, but the edition was bought up and burned by the Romanists in 1529. Other editions were brought out by him, however, in rapid succession, and in 1536, the year in which he suffered martyrdom at Vilvorde, there were no fewer than ten or twelve editions issued from the press. He also published at different times the five books of Moses, with Jonah and Nehemiah. During the reign of Henry VIII. the possession of a copy of Tyndale's translation of the New Testament was sufficient to condemn a person to the flames, but the desire of the people to possess it was irrepressible. "It was wonderful," says an old writer, "to see with what joy the book of God was received, not only among the learned sort, and those who were noted for lovers of the Reformation, but generally all England over, among all the vulgar and common people; and with what greediness God's word was read, and what resort to places where the reading of it was; everybody that could, bought the book, or busily read it, or got others to read it to them if they could not themselves, and divers more elderly people learned on purpose, and even little boys flocked among the rest to hear portions of the Holy Scriptures read." Tyndale's translation forms the basis of all subsequent English versions of the Bible, and in spite of the unfavourable circumstances in which it was made, its high excellence has been acknowledged by the most competent judges. "The language is pure, appropriate, and perspicuous, and the work forms altogether an astonishing monument of the indomitable zeal and great learning of the author."

Coverdale's Bible. An English version of the entire Bible was made by Myles Coverdale, and was published in 1535. It owed its origin to the patronage of Lord Cromwell. As a whole, it must undoubtedly be reckoned inferior to the translation of Tyndale.

Matthews' Bible. After the death of Tyndale, a new edition of his translation was undertaken by his intimate friend John Rogers, superintendent of an English church in Germany, and the first martyr in the reign of Queen Mary. He revised the whole work, and completed the translation of the Old Testament, probably with the assistance of Coverdale's sheets. The whole was completed in 1537, and dedicated to Henry VIII. by the editor, under the assumed name of Thomas Matthews. A license was obtained for publishing the work in England, through the influence of Archbishop Cranmer. A revised edition of this translation was published in London, April 1539, under the superintendence of Richard Taverner, a learned layman.

Cranmer's Bible. The first Bible printed by authority in England was a revised edition of Matthews' or Tyndale's version, with a preface by Archbishop Cranmer, and hence it has been called Cranmer's Bible. In 1540 a copy of this Bible was required by royal proclamation to be placed in every parish church. Two years later, the Popish bishops succeeded in obtaining its suppression by authority of the king. It was restored under Edward VI., suppressed again under Queen Mary, restored again in the first year of Queen Elizabeth, and a new edition of it issued in 1562.

Geneva Bible. A revision of Tyndale's version of the New Testament, by William Whittingham, was printed at Geneva in 1557; and three years later a new translation of the entire Bible was published by Whittingham, Coverdale, Goodman, John Knox, and other exiles. This was the first English Bible printed in Roman letter and divided into verses.

Bible Societies.

Archbishop Parker's, or the Bishops' Bible, was published at London in 1568, and was so named because it was superintended by Archbishop Parker, and eight out of the fifteen translators were bishops.

The Bishops' Bible.

An English translation of the New Testament, made from the Latin Vulgate, and accompanied by annotations, was published at Rheims in 1582. In 1609–10 a translation of the Old Testament from the Vulgate was published at Douay, also with notes. This, which is commonly called the Douay Bible, is the standard version of the Roman Catholics.

Douay Bible.

King James's Bible.

The proposal to undertake a new translation of the Bible originated with Dr John Reynolds of Corpus Christi College, Oxford, in 1603, and was favourably entertained by King James VI., who appointed fifty-four learned men to perform the work. Only forty-seven, however, were actually engaged in the labour. They were divided into six companies, who met at different places, having their respective tasks assigned them. They entered upon their task in 1607, and for three years they were closely engaged in the work. "The translators in King James's time," says Selden, "took an excellent way. That part of the Bible was given to him who was most excellent in such a tongue, and then they met together and one read the translation, the rest holding in their hands some Bible, either of the learned tongues, or French, Spanish, or Italian. If they found any fault they spoke, and if not they read on." When the work was completed, the whole was revised by twelve of the translators, two having been chosen out of each of the six companies. The copy thus revised was again examined by Dr Myles Smith (who wrote the preface), and Dr Bilson, bishop of Winchester. It was first published in 1611, in a folio volume. As the translators were enjoined to follow "the ordinary Bible read in the church, commonly called the Bishops' Bible," and not to make alterations unless the meaning of the original could be more accurately conveyed, the authorized version may be regarded as a revision of the Bishops' Bible, rather than a new and independent work. It is unnecessary to pronounce any eulogium on this translation, which, it has been justly said, "far surpasses every other English version of the entire Bible, in the characteristic qualities of simplicity, energy, and purity of style, as also in uniform fidelity to the original." Selden, Lowth, Horsley, Walton, Middleton, Geddes, Doddridge, Beattie, Scott, Clarke, Stuart, and a host of other eminent divines of different communions, have borne testimony to its general accuracy and high excellence. "A revision of it, however, is now wanted, or rather a new translation from the Hebrew and Greek, based upon it. Since it was made, criticism has brought to light a great mass of materials, and elevated itself in the esteem of theologians as an important science. Hermeneutics, too, have been cultivated, so as to assume a systematic, scientific form. We require, in consequence, a new English version suited to the present state of sacred literature. It need scarcely be stated, that King James's translators have failed to apprehend the true meaning in many passages. Of the merit attaching to their version, a considerable share belongs to Tyndale. Parker's Bible was the professed basis, and *that* was a version of Cranmer's. Cranmer's Bible was chiefly a correction of Matthews', or, in other words, of Tyndale's, so far as Tyndale had translated. Thus King James's translation resolves itself at last in no small measure into Tyndale's; and when we consider the adverse circumstances continually pressing upon that noble-minded man, with the little assistance he could obtain, the work which he produced assumes a pre-eminent position amid the immortal monuments of human learning and skill." (*Biblic. Cyclop.*, vol. ii., p. 919.)

Bible Societies.

BIBLE *Societies*, associations for extending the knowledge of the Holy Scriptures. For a long period this object has been pursued to a considerable extent by several religious institutions, such as the Society for the Propagation of the Gospel in Wales, formed by the Rev. Thomas Gouge, one of the two thousand ministers ejected by the Act of Uniformity in 1662; the Society for Promoting Christian Knowledge, founded in 1698, and which has continued to the present time as the chief Bible Society of the Church of England; the Society for sending Missionaries to India, established in the year 1705 by Frederick IV., king of Denmark, and which has numbered among its agents the celebrated missionary, Christian Frederic Schwartz; the Society for Promoting Christian Knowledge in the Highlands and Islands of Scotland, formed in Edinburgh in 1709; the Moravian Missionary Society, founded in 1732; and the Book Society for Promoting Religious Knowledge among the Poor, which was formed in London in 1750, and numbered among its earliest friends Dr Doddridge and the Rev. James Hervey. But the first British association which had in view the single purpose of disseminating the Scriptures was the NAVAL AND MILITARY BIBLE SOCIETY, established in the year 1780, which has done immense service to the army and navy of Great Britain. The sphere of its operations, however, was comparatively limited, and it was not till 1804 that the BRITISH AND FOREIGN BIBLE SOCIETY, the great institution for the diffusion of the Word of God, was founded. The proposal to institute this association originated with the Rev. Mr Charles of Bala, whose labours in Wales were greatly impeded by the scarcity of the Scriptures in the principality, and it was carried out mainly by the members of the committee of the Religious Tract Society. The exclusive object of the British and Foreign Bible Society is to promote the circulation of the Scriptures, without note or comment, both at home and abroad, and its constitution admits the co-operation of all persons disposed to concur in its support. The committee of management consists of thirty-six laymen, six of them being foreigners resident in or near the metropolis, and of the remaining thirty, one-half are members of the Church of England, and the other half members of other Christian denominations. Every clergyman or dissenting minister who is a member of the society is entitled to attend and vote at all meetings of the committee. Among the early friends of the society were Lord Teignmouth, its first president, Dr Porteus, bishop of London, Admiral Gambier, Charles Grant, now Lord Glenelg, Zachary Macaulay, William Wilberforce, Granville Sharp, and Henry Thornton the first treasurer, and the Rev. Joseph Hughes and John Owen the first secretaries.

The proceedings of the British and Foreign Bible Society have given rise to several controversies, one of which related to the fundamental law of the society to circulate the Bible alone without notes or comments. On this ground it was vehemently attacked by Bishop Marsh, and other divines of the Church of England, who insisted that the Prayer-Book ought to be given along with the Bible. Another controversy, in which the late Dr Andrew Thomson of St George's church, Edinburgh, took a prominent part, related to the circulation on the Continent, by the society, of the Apocrypha along with the canonical books of Scripture. In 1826 it was resolved by the committee that the

fundamental law of the society, which limits its operation to the circulation of the Scriptures, be fully and distinctly recognised as excluding the circulation of the Apocrypha. This step, however, failed to satisfy many of the supporters of the society, particularly in Scotland; and they therefore proceeded to form themselves into independent associations. A third serious controversy by which the society has been agitated, was occasioned by the alleged inaccuracy of some of the translations executed under its authority; and a fourth referred to the admissibility of anti-Trinitarians to the privilege of membership. The refusal of the society in 1831 to alter its constitution so as to exclude such persons, led to the formation of the Trinitarian Bible Society.

The British and Foreign Bible Society soon became the parent of many other associations for the circulation of the Holy Scriptures, and at the present time (1854) there are in Great Britain 445 auxiliaries, 365 branch societies, and 2460 associations; in the colonies, 69 auxiliaries, 280 branches, and 200 associations; in Ireland there are 503; in foreign countries there are about 4000 societies with branches, making a total of 8219 Auxiliary Bible Societies. In the last report of the British and Foreign Bible Society for 1853, it is stated that the society had promoted the distribution, printing, and translation of the Scriptures in 170 languages, not less than 100 of which had never before been reduced to print, while 25 had previously no written language at all; and that it had been the means of circulating not less than 45,000,000 copies of the Bible; of which number 18,000,000 had been distributed in Great Britain and Ireland, 17,000,000 in Europe, 8,000,000 in America, and 2,000,000 among Jews, Mahometans, and heathens in other parts of the world. The total sum expended by the society since its formation has been L.3,950,953. The most active of the Continental associations are those of Berlin, Basle, Paris, Wirtemburg, Dresden, Sweden, and the Netherlands. The Central Prussian Society has issued since its commencement upwards of a million and a half copies of the Scriptures; a million copies have been circulated in Sweden during the last thirty-two years; the French and Foreign Bible Society distributed last year 28,000 copies. The Russian Society at St Petersburg, instituted in 1813, before its suspension by an imperial ukase in 1826, had 289 auxiliaries and branches, and had printed 861,105 Bibles and Testaments in various languages and dialects.

The Edinburgh Bible Society originated in the controversy respecting the circulation of the Apocrypha along with the canonical books, and is composed of Protestants professing their belief in the doctrine of the Holy Trinity, and disposed to co-operate in promoting the dissemination of the Scriptures. Its funds arise from subscriptions, collections, and the contributions of about fifty branch societies in different parts of Scotland. The average annual revenue of the society for the last three years has been about L.2900, and it distributes annually about 3500 Bibles, a large portion of which are Gaelic copies of the Scriptures circulated in the Highlands and Islands of Scotland, and in the colonies.

The Scottish Bible Society was instituted upwards of forty years ago. At the time of its establishment, the other Bible Societies in Scotland employed their funds chiefly in circulating the Scriptures in foreign countries. This association was intended exclusively for the distribution of the Bible at home, and its funds were at first derived from collections made in the parish churches within the synod of Lothian and Tweeddale, but they have since been augmented by various legacies. The annual revenue, derived chiefly from capital, is nearly L.300. This is employed in furnishing to the poor at a reduced price, and in some cases gratuitously, copies of the word of God in English and Gaelic. The distribution is almost wholly made through the Scottish parochial ministers.

The first Bible Society in America is believed to have been established by a few Baptists in New York in 1804; its object was to purchase and lend Bibles for a month at a time. The Philadelphia Bible Society, which was instituted December 12. 1808, was for some years the only association in the country for the gratuitous distribution of the Sacred Scriptures.

The American Bible Society was formed at New York May 8. 1817. It has numerous auxiliaries throughout the several states of the Union. In 1853, its income amounted to 308,744 dollars, besides large sums for its new premises —an immense Bible-house in New York. Its issues during that year were 666,015 Bibles and Testaments.

The exclusive privilege of printing the Scriptures in Scotland belonged to the queen's printers, and some years ago they instituted a law-suit against the various Scottish Bible Societies, and succeeded in obtaining an interdict preventing the importation into Scotland of Bibles printed beyond the bounds of that country. On the expiry of the monopoly however, in 1839, the House of Commons, mainly through the exertions of the Rev. Dr Adam Thomson of Coldstream, refused to renew the patent, and appointed a Bible Board for Scotland, with power to grant licenses to print the authorized version of the Scriptures. A great reduction immediately took place in the price of the sacred volume, the circulation of which has been in consequence immensely increased. The monopoly of the right to print the Bible in England is still possessed by the Universities of Oxford and Cambridge, and Her Majesty's printer for England. But after a controversy which was carried on for some time with great warmth (1840–1), intelligence and justice prevailed, and the prices of the common Bibles and Testaments were reduced, in some instances more than one-half, to their present remarkable cheapness.

See Owen's *History of the First Ten Years of the British and Foreign Bible Society; Bible Triumphs, a Jubilee Memorial for the British and Foreign Bible Society.* (J.T.)

BIBLIANDER, or more properly Theodore Buchmann, a learned Swiss Protestant divine, born at Bischoffzell in 1504. On the death of Zwingle he was appointed professor of theology at Zurich in 1532. Having adopted more liberal sentiments on the subject of predestination and free-will than were agreeable to his party, he was deprived of his professorship after having long discharged its duties with high reputation. He was a learned Oriental scholar, and published an edition of the Koran, to which he prefixed lives of Mahomet and his successors; together with an apologetical preface, which, in the words of Bayle, "raised a great outcry." Besides this, he published numerous works, chiefly on theology and ecclesiastical history. He died of the plague at Zurich in 1564.

BIBLIOGRAPHY.

That branch of knowledge to which the term Bibliography is generally applied would be more correctly designated by the word *Bibliology*. It was originally employed to denote skill in the perusing and judging of ancient manuscripts; but it is now appropriated to the knowledge of books with reference to their constituent parts, their different editions and degrees of rareness, their subjects, and classes.

Bibliography. This species of knowledge has been most successfully cultivated in France, Germany, and Italy; for though it will be seen in the sequel, that Britain has produced some valuable works in this department, it will also appear that our bibliographical labours have been greatly surpassed by the continental nations. It is to France, in particular, that we are indebted for the most popular and useful treatises in bibliography; but whilst we make this acknowledgement, in which all who have had any experience of their utility will concur, we must add, that some of her bibliographers have spoken in very extravagant terms of the nature and rank of this branch of learning. They represent it as a universal science, in whose ample range all other sciences, and all other kinds of knowledge, are comprehended. "La bibliographie étant la plus étendue de toutes les sciences, semble devoir les renfermer toutes," is the language of one;[1] "la bibliographie est la plus vaste et la plus universelle de toutes les connoissances humaines," is the language of another.[2] Nothing surely can be more preposterous than to view it in this light, merely because it is conversant about books, and because books are the vehicles of all sorts of knowledge. Yet this is the only foundation that we can discover for these extravagant representations; which tend, as in all other cases of exaggerated pretension, to bring ridicule upon a subject which, were its nature and objects simply and correctly defined, could not fail to appear both useful and important. We have already stated generally what kind of knowledge it is to which the appellation of bibliographical knowledge is applied; but, in order more fully to illustrate its nature, and to point out its limits and utility, we shall endeavour to detail somewhat more particularly the chief objects of inquiry which it embraces.

It is the business of the bibliographer, then, to trace the history of books in regard to their forms and all other constituents, and, consequently, to trace the beginnings and progress of typography. It belongs to him, in a particular manner, to mark the differences of editions, and to point out that edition of every book which is esteemed the most correct and valuable. In the case of books published anonymously, or under feigned names, it is his business to indicate the names of their real authors, in as far as the discoveries of literary history may furnish the means of doing so. All remarkable facts attaching to the history of books, such as the number of their editions, their rareness, their having been condemned to the flames, or suppressed, belong to the province of bibliographical inquiry. Further, every one who engages in any particular line of study must of course wish to know what books have been published in regard to it, or in regard to any particular point that interests his curiosity; and it is the business of the bibliographer to furnish this most useful species of information; in other words, the compilation of catalogues of those books which have appeared in the various branches of knowledge constitutes another department of bibliography. It is by means of such catalogues that "the student comes to know what has been written on every part of learning; that he avoids the hazards of encountering difficulties which have already been cleared; of discussing questions which have already been decided; and of digging in mines of literature which have already been exhausted." (Dr Johnson's Preface to the *Catalogus Bibliothecæ Harleianæ.*)

Such are the principal objects and pursuits of the bibliographer; and while it must appear abundantly evident that his science has no pretensions to those lofty epithets upon which we have animadverted, it must, we think, be allowed by every one that it comprises many curious as well as interesting subjects of inquiry; and that it is calculated to afford very useful aids to every other species of intellectual occupation. This view of it will be fully confirmed by the details which we are to offer in the course of this article; in which we propose to point out the progress and best sources of information, in all those departments of knowledge to which we have alluded. In doing so, we shall divide the subject into such heads as shall appear best suited to the purposes intended. Bibliography.

1. *Of the Constituent Parts of Books, and the Differences of Editions.*

The history of the materials employed in the formation of books, of the art of writing and printing upon these materials, and of the forms and sizes in which they have appeared, all belong to this head of inquiry.

Much curious learning has been exercised in describing the various substances used for writings previously to the important discovery of the art of making paper from linen rags. The precise era of this discovery is not known, nor are authors agreed as to the country in which it was made; but it seems to be ascertained that this kind of paper was in general use in Europe before the end of the fourteenth century. Cotton paper had been in general use more than a century before; and though of greatly inferior quality, its introduction was one of the most fortunate circumstances in the history of the arts; for parchment had become so scarce, that old writings were often erased in order to apply the parchment to modern purposes; and thus, by a metamorphosis of a singular and fatal kind, a classic was sometimes transformed into a vapid homily or monkish legend. In this way it is supposed that many valuable works of antiquity have perished; and, indeed, there can be little doubt of this when we consider the number of manuscripts that have been discovered, evidently written upon erased parchments. Parchments of this kind have been called *palimpsests*, from a Greek word signifying twice rubbed—that is, prepared for writing (*Edinburgh Review*, No. xcvi., p. 367). Dr Barret of Trinity College, Dublin, discovered a palimpsest while examining some books in the library of that college. "When thus employed he accidentally met with a very ancient Greek manuscript, on certain leaves of which he observed a twofold writing, one ancient, and the other, comparatively recent, transcribed over the former. The original writing had been greatly defaced; but on close examination he found that it consisted of the three following fragments:—The Prophet Isaiah, the Evangelist St Matthew, and certain Orations of Gregory Nazianzen. The fragment containing St Matthew's Gospel Dr Barret carefully transcribed, and it has been accurately engraved in fac-simile, and published by the order and at the expense of the University, Dublin, 1801, 4to. The original writing, or *Codex Vetus*, Dr Barret, with great probability, assigns to the sixth century; the *Codex Recens*, or later writing, he attributes to the thirteenth" (Horne's *Introduction to Bibliography*, i., p. 115). There has recently appeared "*The Codex Montfortianus*, a collation of this celebrated MS. in the library of Trinity College, Dublin, throughout the Gospels and Acts, with the Greek text of Wetstein, &c.," by O. T. Dobbin, LL.D., 1854, 8vo. But the most interesting discoveries in this line are those of the Cardinal Angelo Maio, who held the office of keeper of the Vatican library, to whom we are indebted for a considerable fragment of Cicero *de Republica*, and fragments of three of his lost orations. The reader will find a curious account of these discoveries, and of the

Bibliography.

history of *palimpsests*, in the above-cited article of the *Edinburgh Review*.

That part of the history of books which regards the various substances upon which they have been written is compendiously but learnedly treated in the first volume of that very valuable work, the *Nouveau Traité de Diplomatique*, compiled by two Benedictines of the celebrated society of St Maur. This work was published at Paris in 1750, in six volumes quarto. M. Peignot gives a complete list of separate works on this subject in the introduction to his *Essai sur l'Histoire du Parchemin et du Vélin*, published at Paris in 1812.

The inquiry as to the origin of writing is a purely philosophical speculation; but the knowledge of the different kinds of writing peculiar to different ages is a branch of the history of books, which belongs to the province of bibliography, and upon which much information will be found in the above-mentioned work of the Benedictines of St Maur. An excellent work on this subject is Mr Astle's *Origin and Progress of Writing*, the first edition of which was published in 1784, and the second, with some additions, in 1803, each in one volume quarto. The chapters on transcribers and illuminators, and the instruments, inks, and other matters which they made use of in their operations, will be found peculiarly interesting to the bibliographer. But modern art has produced works of a similar character, unrivalled for splendour and execution, in furnishing facsimiles of ancient manuscripts. Without referring to the great work of Count Bastard, limited, from its expense, to crowned heads, we may specify Westwood's *Paleographia Sacra Pictoria*, 1845; Shaw's *Illuminated Ornaments*, 1833; Silvester's *Paléographie Universelle*, Paris, 1839–41, 4 vols. large folio; and *The Illuminated Books of the Middle Ages*, by H. N. Humphreys, and illustrated by Owen Jones, 1849, large folio.

We are now so familiar with the wonders and glorious results of printing, that it is only when we look back into the history of the darker ages that we are made fully sensible of all the various advantages which it has conferred upon mankind. The mention of the *transcribers*—that is, the class employed to copy books before the discovery of printing, naturally gives rise to reflections of this kind. Their ignorance and carelessness occasioned much trouble and mortification to living authors, and irreparable errors in the works of the dead. Petrarch, who flourished in the fourteenth century, has expressed himself in very moving terms in regard to this evil. "How shall we find out a remedy," says he, "for those mischiefs which the ignorance and inattention of the copyists inflict upon us? It is wholly owing to these causes that many men of genius keep their most valuable pieces unpublished, so that they never see the light. Were Cicero, Livy, or Pliny, to rise from the dead, they would scarcely be able to recognise their own writings. In every page they would have occasion to exclaim against the ignorance and the corruptions of those barbarous transcribers."[1] Upon the invention of printing, the class of copyists immediately took alarm, and exerted every means to extinguish an art which, whatever benefits it promised the rest of mankind, held out nothing but prospects of loss to them. They endeavoured, and their example is still steadily followed by other crafts, to set up their own petty interests in opposition to the general good, and called loudly upon the different governments to invest them with exclusive privileges, which all the great interests of society required to be abolished. Thus, when printing was introduced at Paris, the copyists complained of the innovation to the parliament, and that body forthwith caused the books belonging to the printers to be seized and confiscated; but Louis XI. had the good sense to restore their property to these ingenious artists, and to authorize them to proceed in their laudable vocation.

Bibliography.

The question as to the origin of printing is of a complexion wholly different from that regarding the origin of writing, as it turns entirely upon matters of fact; but it is not the less true that it is a subject upon which opinions widely opposite are still entertained; for though this art—we mean the art of printing with moveable types—was spread all over Europe within twenty years of the first discovery, it has unfortunately failed to record, in decisive terms, the name of the individual to whom the honour of the invention is due. The place where the discovery was made remains also a subject of doubt and contention. In Mallinkrot's work, *De Ortu et Progressu Artis Typographicæ*, published in 1640, he enumerates a hundred and nine testimonies in favour of Mentz as the birth-place of the art, and since that time the number has been greatly augmented; yet one of the latest of those who have engaged in this controversy declares decidedly in favour of Haerlem, which, in Mallinkrot's day, ranked only thirteen advocates; and further, assigns the wreath which the supporters of Mentz had variously placed on the brow of Gutenberg, of Fust, and of Schoiffer, to Lawrence Coster, as its rightful owner.[2] All that we can do in this place is to point out some of the works which have been published upon the origin and history of printing, and which it may be necessary for the bibliographer to examine, in order to enable him to judge of early editions; recommending those who wish to see a clear and compendious view of the various opinions which have been advanced upon this subject, to peruse M. Daunou's analysis of these opinions, published in the fourth volume of the *Memoires* of the Moral and Political Class of the French Institute.

The *Monumenta Typographica* of Wolfius, published in two octavo volumes at Hamburg in 1740, contains a collection of treatises by various authors, and also of extracts illustrative of the origin and early history of the art. Among other elaborate tables it contains one of all the authors who, up to that time, had either directly or indirectly treated of the history or of the mechanical part of printing. Meerman's *Origines Typographicæ* is one of the most instructive works as to the progress of the art. It is illustrated with various specimens of early printing, and fac-similes of the books called *Block-Books*, printed by means of wooden blocks. Meerman, who was a lawyer, and author of many elaborate treatises in the civil and canon law, was born at Leyden in 1722, and died in 1771, six years after the publication of his *Origines*; in which he supports, with great ardour and learning, the pretensions of Haerlem as the birth-place of the art, and of Lawrence Coster as its inventor. Another work of curious research on the origin and first progress of printing is that of Prosper Marchand, originally a bookseller at Paris, but whom the repeal of the edict of Nantz drove to Holland, where he employed himself till his death in 1756 in composing various works in literary history and bibliography. He makes Gutenberg the inventor of the art, and Mentz the place where he completed the invention; the first idea of it, however, having been formed whilst he resided in Strasburg. This work, entitled *Histoire de l'Origine et des premiers Progrès de l'Imprimerie*, was published in 1740. A valuable supplement, in which some errors of Marchand are corrected, was published by M. Mercier, abbé de Saint Leger, in 1773, and republished in 1775. The opinion that Gutenberg conceived the first idea of the invention at Strasburg, and afterwards completed it at Mentz, is also supported by Lambinet in his *Recherches historiques, littéraires, et critiques sur l'Origine de l'Impri-*

[1] Lambinet, *Origine de l'Imprimerie*, tome i., p. 38, 39.
[2] See Ottley's *Inquiry into the Origin and early History of Engraving*, chap. iii.

Bibliography.

merie, first published at Brussels in 1799, and republished in two volumes octavo at Paris in 1810, with the addition of M. D. Daunou's treatise already mentioned. Besides the main subject of inquiry, M. Lambinet's work includes various other topics,—such as the history of the substances employed for books, of inks, of engraving in relief, of block-printing, and of stereotype printing. Upon the history of printing we shall mention M. de la Serna Satander's Essay prefixed to his *Dictionnaire Bibliographique*, and the *Initia Typographica* of Professor Lichtenberger, published at Strasburg in 1811; in both of which the claims set up for Coster are treated as fabulous, Gutenberg being represented as the inventor of the art, and Mentz the place where it was perfected; and in both of which also there are ample details as to its progress in other cities and countries.

Several later works might be specified, such as Schaab's *Die Geschichte der Erfindung der Buchdruckerkunst durch Jo. Gensfleisch genannt Gutenberg zu Mainz*, 1830, 3 vols. 8vo; Wetter's *Kritische Geschichte der Erfindung der Buchdruckerkunst durch Johann Gutenberg*, 1836; Laborde's *Debut de l'Imprimerie a Strasbourg*, 1840. Nor ought we to overlook the valuable work of Dr Karl Falkenstein, *Geschichte der Buchdruckerkunst in ihrer Entstehung und Ausbildung*, 1840, 4to. On the other hand, in favour of Costar's claims, we may notice A. de Vries *Eclaircissements sur l'Histoire de l'invention de l'Imprimerie*, 1843. Without entering upon this long disputed question, we may state generally that although Lawrence Coster and other printers *may* have employed types cut in wood at a still earlier period, the true inventor of moveable types, to which the Art of Printing owes its chief importance, was John Gutenberg, in Mentz, between 1445 and 1450.

Besides the information afforded by these general histories as to the diffusion of printing throughout Europe, there are various treatises on its establishment in particular countries and places, which it will often be necessary for the bibliographer to consult. The most valuable to the English bibliographer is Ames's *Typographical Antiquities*, which contains memoirs of our early printers, and a register of the publications from 1471 to 1600. The first edition, published in 1749, consisted of one volume quarto. Another edition, enlarged by Mr Herbert to three volumes quarto, was completed in 1790; and a third, printed with great elegance, and richly embellished, was commenced in 1810, but the fourth volume, published in 1819, left the latter half of Herbert's work untouched. The plan was injudicious, and the editor, the Rev. Dr Dibden, laid no claims to that minute accuracy and research so requisite for a work of that kind, and which renders Herbert's volumes so useful. The French, Germans, and Italians, particularly the latter, are rich in typographical histories of this description; but for accounts of them we must refer our readers to Peignot's *Répertoire Bibliographique Universel*, where they are enumerated and described. There is, indeed, scarcely a town of any importance in Italy, France, Germany, and even in Sweden, which has not a separate treatise describing their earliest printed works, usually known abroad by the general name *Incunabula*. We may likewise mention a curious and interesting work, *The History of Printing in America, with a Biography of Printers*, by Isaiah Thomas, Worcester (Massachusetts), 1810, 2 vols. 8vo.

A knowledge of the different founts or kind of letters used in printing is necessary to the accurate description of books. The bibliographer must also be acquainted with the corresponding appellations used by foreign printers in regard to the different kinds of type. Thus the fount named *pica* by English printers, is called *cicero* by those of France and Germany, because Cicero's *Epistles* were printed in that type. The fount called *paragon* is the only one which retains the same name among the printers of all countries. Upon all these points, Stower's *Printer's Grammar*, 1808; Fournier's *Manuel Typographique*; Johnson's *Typographia, or the Printer's Instructor*, 1812, 2 vols. 12mo; Hansard's *Typographia; an Historical Sketch of the Origin and Progress of the Art of Printing*, 1825, royal 8vo; and Savage's *Practical Hints on Decorative Printing*, 1822, folio, may be consulted with advantage.

Bibliography.

The books of the ancients were generally in the form of cylinders, made by rolling the joined sheets upon a stick, to the ends of which nobs or balls were affixed, often richly ornamented. In the infancy of printing the sizes were generally folio and quarto; and some have supposed that no books were printed in the smaller forms till after 1480; but M. Peignot instances many editions in the smallest forms, of an earlier date, as may be seen in the article *Format* of the Supplement to his *Dictionnaire de Bibliologie*. An accurate knowledge of the different forms of books is necessary to the bibliographer, as without it no book can be correctly described; and however easy of acquisition this knowledge may appear, it is yet certain that errors in this respect are sometimes committed even by experienced bibliographers, and that doubts have been entertained as to the existence of editions, owing to their forms having been inaccurately described.[1] These mistakes generally proceed from this, that there are different sizes of paper comprehended under the same name. But the water-lines in the sheets afford a test, as they are uniformly perpendicular in the folio and octavo, and horizontal in the quarto and duodecimo sizes.

When books have gone through more than one edition, various minute inquiries must often be made, in order to determine the respective merits of those editions. It is a principal object of the bibliographical dictionaries, to be afterwards mentioned, to point out those editions of important works which such inquiries have ascertained to be the best. There are sometimes differences between copies of the same edition of a work;[2] and which, therefore, stand to each other in the same relation as if there had been another edition, with some variations. Walton's *Polyglot Bible* is a celebrated instance. The printing of that great work, for which Cromwell liberally allowed paper to be imported free of duty, was begun in 1653, and completed in 1657, and the preface to it, in some copies, contains a respectful acknowledgement of this piece of patronage on the part of the Protector; but in other copies the compliment is expunged, and replaced by some invectives against the republicans—Dr Walton having, on the Restoration, printed another preface to the copies which had not by that time been disposed of.[3] The copies with the original preface are much rarer, and of course more prized, than those with the loyal one, which latter seems to have helped the author to the bishopric he afterwards obtained.

II. *Of Early Printed Books.*

The productions of the press in the different countries of Europe, during the century in which printing was invented, have engaged much of the attention of bibliographers, and have been described in various works compiled for that purpose. The first of those productions to which the name of

[1] See Boulard, *Traité Elémentaire de Bibliographie*, p. 38, 39.

[2] The *Voyage to Cadiz*, in the second edition of Hakluyt's *Collection*, 1598–1600, having been suppressed in many copies, a reprint is often inserted to supply this want. This reprint may be known from the original by this mark, that it has only seven paragraphs in p. 607, vol. i., whereas the original has *eight*. The *original* ends on p. 619, the *reprint* on p. 620.

[3] See vol. i. of Dr Clarke's *Bibliographical Dictionary*, for some curious details on this point.

Bibliography.

Books has been applied, were printed, not with moveable types, but with solid wooden blocks, and consisted of a few leaves only, on which were impressed images of saints, and other historical pictures, with appropriate texts or descriptions. These leaves were printed only on one side, and the blank sides were generally, though not always, pasted together, so as to look like single leaves. The ink used was of a brownish hue, and glutinous quality, to prevent it from spreading. These curious specimens of the infant art are called *Image Books* or *Block Books*. They have often been largely described, every particular concerning them having been fondly canvassed by bibliographers. Their number is fixed by some at seven, by others carried to ten; but there have been numerous editions of most of them; for they maintained their popularity long after the invention of the art of printing properly so called. One of the most celebrated is the *Biblia Pauperum*, consisting of forty leaves printed on one side, so as to make twenty when pasted together; upon which certain historical passages of the Old and New Testament are represented by means of figures, with inscriptions. It was originally intended, as its name imports, for the use of those poor persons who could not afford to purchase complete copies of the Bible. There is a copious account of *Block Books* in Baron Heinecken's learned work, *Ideé générale d'une Collection complette d'Estampes*, published in 1771, octavo. Dr Dibdin's *Bibliotheca Spenceriana* contains fac-similes of the figures in several of them, as does Mr Ottley's *History of Engraving*, and Falkenstein's work, already mentioned. But a large and laborious publication, by Mr Sotheby, entitled *Principia Typographica*, in 3 vols., specially devoted to an account of wooden-block printed books, with fac-similes, may be soon expected, and will no doubt prove a most important bibliographical work, and throw much light on the early history of printing.

The first book of any considerable magnitude printed with moveable metallic types was the celebrated *editio princeps* of the Bible, printed at Mentz, between the years 1450 and 1455. It is printed in large but handsome Gothic characters, to resemble manuscript, having two columns in the page, and consisting in whole of 637 leaves: it is usually divided into two volumes. The advance from the rude *Block Books* of a few leaves to this noble monument of early typography is great indeed; and it is impossible not to regret that there should have been any uncertainty as to the person whose ingenuity furnished the means of at once raising almost to perfection an art destined ever after to exercise so vast and so beneficial an influence on the affairs of the world. The *Psalter*, printed at Mentz by Fust and Schoiffer, in 1457, is a magnificent specimen of printing, and is moreover the first book which bears the printer's name, with the date and place of printing.

In general, in the very early printed books, the name of the printer, the date,[1] and the place of printing, are either wholly omitted, or placed at the end of the book, with some quaint ejaculation or doxology. The pages have no running title, or number, or catch-word, or signature letters[2] to mark the order of the sheets. The character is uniformly Gothic till 1467, when the Roman type was first introduced. There were no capitals to begin sentences, blank spaces being left for the illuminator to supply them according to his fancy; the only points used were the colon and full stop; and in almost every sentence there were abbreviations or contractions. In regard to these and other peculiarities of early printed books, the reader may consult the following works:—*The General History of Printing*, by Palmer, (supposed, however, to have been chiefly written by the celebrated George Psalmanazar); Jungendres, *De Notis characteristicis Librorum a Typographiæ incunabulis ad an.* 1500 *impressorum*; and, *Recherches sur l'Origine des Signatures, et des Chiffres de Page*, par Marolles.

Many of the early printers had peculiar marks or vignettes, which they sometimes placed on the title-page, sometimes at the end of the books printed by them; and most of them also made use of monograms or ciphers, compounded of the initial or other letters of their names. These furnish a clue to the discovery of the printer, where they occur on books without any printer's name. An acquaintance with them, therefore, is necessary to the bibliographer, because questions occur as to early editions which can only be decided by ascertaining the printer's name. For explanations of these marks, the following works may be consulted:—Orlandi's *Origine e Progressi della Stampa*, published at Bologna in one volume 4to, in 1722; and Scholtzius's *Thesaurus Symbolorum ac Emblematum*, in one volume folio, published at Nuremberg in 1730. The monograms of the early English printers are explained in Ames's *Typographical Antiquities*.

The following works may be mentioned as among the best of those that have been devoted to the description of early printed books:—1. *Index Librorum ab inventa Typographia ad annum* 1500, *cum notis*, 2 vols. 8vo, 1791. This work, by Laire, is one of the most useful of its kind. The descriptions are clear, the notes brief and instructive; and there are four indexes, which furnish the means of ready reference to all the names, titles, places, and bibliographical notices contained in the work. 2. *Dictionnaire Bibliographique choisi du quinzième siècle*, par M. de la Serna Santander, 3 vols. 8vo, 1805. This is a very learned and exact work; and, like the preceding one, embraces only the rarest and most interesting publications of the fifteenth century. 3. *Bibliotheca Spenceriana*, or a descriptive catalogue of the books published in the fifteenth century, in the library of Earl Spencer, by the Rev. T. F. Dibdin, 4 vols. royal 8vo, 1814; to which was added the *Ædes Althorpianæ*, including a Supplement to the *Bibliotheca Spenceriana*, 1822, 2 vols.; and the additional volume of the *Cassano Library*, with the general index, in 1823. The abundance and beauty of the fac-similes and other embellishments, as well as the fineness of the paper and printing, render this one of the most splendid bibliographical works ever published in any country. It contains some curious information, enveloped, however, in a reasonable proportion of tasteless and irrelevant matter. 4. *Annales Typographici ab artis inventæ origine*, by Michael Maittaire, published in 4to, as follows:—In 1719, volume first, which embraces the period from the origin of printing to 1500; volume second, published in 1722, extends the annals to 1536; and volume third, published in 1726, brings them down, according to the title-page, to 1557; but there is an appendix which affords a partial continuation to 1664. In 1733 the first volume was republished, with corrections and large additions, and is commonly called the fourth volume. The fifth and last volume, containing indexes, was published in 1741. As four of the volumes consist each of two parts, the work is sometimes bound in five, sometimes in nine volumes. A supplement to this elaborate work by Denis, in 2 vols. 4to, was published at Vienna in 1789, and contains 6311 articles omitted by Maittaire. The latter has enriched his annals with many learned dissertations; and the work is allowed to be the most important that has yet been compiled in England, in any department of bibliography; but though written in this country,

[1] Early printed books are often found with erroneous or falsified dates (Middleton, vol. iii., p. 236). Dates are sometimes computed by *Olympiads* (*Ibid.*, p. 241).

[2] *Signatures* are letters of the alphabet placed at the bottom of the page, to show the order of the sheets and leaves. "They were used at Cologne, an. 1475; at Paris 1476; by Caxton, not before 1480" (Middleton's *Works*, vol. iii., p. 238).

Bibliography.

the last was the only volume published in it, the others having been given to the world in Holland. 5. *Annales Typographici ab artis inventæ origine, ad annum* 1500, *post* MAITTAIRII, DENISII, *aliorumque doctissimorum virorum curas in ordinem redacti, emendati, et aucti, opera S. W.* PANZER, 11 volumes 4to, published at Nuremberg, the first in 1793, the last in 1803. It was intended, according to the title-page of the first volume, to be limited to the fifteenth century, but, after the appearance of the fifth volume, the period was extended to the year 1536; the author reserving for a separate work books in the German language. This latter work bears the title *Annalen der Altern Deutschen Litteratur*. A more recent publication by Lud. Hain is entitled *Repertorium Bibliographicum, in quo Libri omnes ab arte Typographica inventa usque ad Annum MD. Typis expressi ordine alphabetico vel simpliciter enumerantur vel adcuratius recensentur*, 4 vols. 8vo, 1826-38, and no less than 16,299 books printed during the fifteenth century in general, are described with a minute accuracy which is so rarely to be met with. But the author did not survive to put the finishing hand to his work, after it had reached the letter *Ug*, which may account for the entire omission of *Virgilius*, &c. The addition of bibliographical notices, pointing out first editions and books of remarkable rarity and value, would have much enhanced its interest and value.

The works just described are quite indispensable to every bibliographical collection; but they have a value, we think, independent of the assistance which they afford the bibliographer in his examination of the early productions of the press; they are also calculated to interest the philosopher as curious registers of the extent and objects of intellectual industry during a period when the human mind began to be acted upon by many new impulses, and to receive the seeds of revolutions destined to change the whole aspect of the intellectual world.

III. *Of Rare Books.*

Rareness is a circumstance which must, generally speaking, confer some degree of value upon books; and it is therefore one of the objects of bibliography to indicate those books which, in a greater or less degree, come under this category. We cannot, in this department, any more than in others, indicate any but the most prominent and useful books belonging to it. The following, in this view, are particularly worthy of attention:—1. Beyeri *Memoriæ historico-criticæ Librorum rariorum*, 1734, 8vo. 2. Vogt, *Catalogus historico-criticus Librorum rariorum*, 1732, 8vo. The last and best edition was published in 1793. In this work the epithet *rare* is applied with more judgment and knowledge than in most others of the same class. 3. Gerdesii *Florilegium historico-criticum Librorum rariorum;* first published in 1740, and again in 1763, in 8vo. It was partly intended as a supplement to the above work by Vogt, and therefore notices only those books which are not included in his catalogue. 4. *Bibliothèque curieuse, ou Catalogue raisonné des Livres rares*, par D. Clement, 1750-60. This work, to which we have just alluded, is compiled upon a more extensive plan than any of the preceding; for, though consisting of 9 volumes quarto, it comes down no farther than to the letter H in the alphabetical arrangement of names; terminating here in consequence of the death of the author. Clement is generally blamed, and with justice, for a very profuse and inaccurate application of his own nomenclature; his notes, too, are crammed with citations, and tediously minute; but, on the other hand, it must be allowed that they contain many curious morsels of literary history; and it has, upon the whole, been matter of regret to bibliographers, that the work, voluminous as it must have proved, was not completed. 5. *Bibliotheca Librorum rariorum universalis.* Auctore Jo. Jac. Bauer, 7 vols. 8vo, 1770-91. Bibliography.

Books printed upon Vellum have always been objects of special interest to collectors, from the limited number of copies printed, their beauty, and extreme rarity. Panzer, in his *Essai sur l'Histoire du Parchemin et du Velin*, 1812, announced his intention of publishing a *Bibliothèque rare et précieuse, entièrement composée d'ouvrages imprimées sur Velin.* This work never appeared, but its place was well supplied by an eminent French bibliographer, M. Van Praet, in his *Catalogue des Livres imprimés sur Velin de la Bibliothèque du Roi*, 1822-28, 6 vols., and his Supplemental Catalogue of similar books in other libraries, 1824, 4 vols. royal 8vo.

Various causes contribute to give a degree of rarity and value to particular books, such, for instance, as the casual destruction of most of the copies,—as in the case of the second volume of Hevelius' *Machina Cœlestis*, 1679; the third volume of Rudbeck's *Atlantica*, 1698; and the few sheets printed of a fourth volume. At the great fire of London, in 1666, there were many works of which only a limited number of copies escaped, such for instance as some of Dugdale's works (but their value has been reduced by subsequent editions), and the first volume of Prynne's great work known as the *Records of the Tower.* Other books, again, owe their rarity to the circumstance of only a few copies having been printed for private circulation. Of this class of English books, there has appeared *A Bibliographical Catalogue of Books Privately Printed*, by John Martin, 1834, and republished, with additions, in 1854, 8vo.

IV. *Of the Classics.*

It is remarked by Mr Roscoe, "that the coincidence of the discovery of the art of printing with the spirit of the times in which it had birth was highly fortunate. Had it been made known at a much earlier period it would have been disregarded or forgotten, from the mere want of materials on which to exercise it; and had it been farther postponed it is probable that many works would have been totally lost which are now justly regarded as the noblest monuments of the human intellect." (*Lorenzo de' Medici*, chap. i.) The rapid diffusion of the art, and the speedy appearance of the *Classics* in an imperishable form, afford sufficient proofs of the bent of the age, and the opportuneness of this great discovery. Gabriel Naudé observes, that almost all the good as well as bad books then in Europe had passed through the press before the year 1474;[1] that is, within twenty years of the earliest date to which the use of moveable types can be carried. Within this period editions had been printed of nearly all the Latin classics. The whole works of some of them—of Cicero, for example—had not yet appeared in one uniform edition; but several of his treatises, the whole of Pliny the elder, of Livy, Sallust, Cæsar, Tacitus, Suetonius, Justin, Lucan, Apuleius, Terence, Ovid, Juvenal, Quintus Curtius, Virgil, and Horace, had been published before the end of 1471. Most of the early editions of the classics were published in Italy. England remained greatly behind her continental neighbours in the naturalization of these precious remains of ancient learning. Of all the classics, only Terence, Virgil, Sallust, and Cicero's *Offices*, had, in 1540, been published in this country in their original tongue. In 1591, a neat edition of the Greek text of Homer's *Iliad* was first printed at London. Caxton and others made use only of French translations in the early versions and abridgements published in England. Gawin Douglas, bishop of Dunkeld, so well known for his poetical version of Virgil, has, in his preface to that work, commemorated his indignation at the injustice done to "the divine

[1] *Addition à l'Histoire de Louis XI.*, par G. Naudé.

poet" by Caxton's second-hand translation in the following curious and emphatic lines:—

"Thoch Wylliame Caxtoun had no compatioun
Of Virgill in that buk he preyt in prois,
Clepand it Virgill in Eneados,
Quhilk that he sayis of Frensche he did translait,
It has nathing ado therwith, God wate,
Nor na mare like than the Deuil and sanct Austin.
Haue he na thank tharfore, bot lois his pyne;
So schamefully the storie did peruerte,
I reid his work with harmes at my hert,
That sic ane buk, but sentence or ingyne,
Suld be intitulit eftir the poete diuine.
His ornate goldin versis mare than gylt;
I spitte for disspite to se thame spylt
With sic ane wicht, quhilk treuly be myne entent
Knew nevir thre wordis at all quhat Virgill ment."

Almost all the Latin classics had appeared in print before the art was employed upon any Greek author. But the desire to possess printed editions of the latter became general and urgent towards the end of the fifteenth century; and Aldus had the glory of ministering to that desire, by publishing, in rapid succession, and with singular beauty and correctness, almost all the principal authors in that tongue. Beginning, in 1494, with Musæus's *Hero and Leander*, he printed before 1515, the year of his death, upwards of 60 considerable works in Grecian literature, frequently superadding the learning and cares of the editor to those of the printer. "Yet his glory," to use the words of Mr Gibbon, "must not tempt us to forget that the first Greek book, the *Grammar* of Constantine Lascaris, was printed at Milan in 1476; and that the Florence *Homer* of 1488 displays all the luxury of the typographical art" (*History*, chap. 66). Besides these works, there had been published before 1494 some Greek *Psalters*, the *Batrachomyomachia* of Homer, and the *Orations* of Isocrates; during that year the *Anthologia Græca* was published at Florence; and the works of Callimachus, of Apollonius Rhodius, and of Lucian, were published at the same place within two years after the first essays of Aldus in Greek printing. Thus, though we have no sort of wish to detract from the just fame of this learned and beautiful printer, we cannot admit the propriety of those eulogies of his biographer, M. Renouard, in which he is represented as having given an entirely new direction to the art of printing, and indeed to the literary taste of Europe.[1] It is as incorrect in point of fact as it is unphilosophical, to ascribe to Aldus the production of that taste for Grecian literature which he himself imbibed from the spirit of his age. He saw that there was a great and growing want of Greek books; and his peculiar praise lies in this, that he applied himself to supply it with much more constancy and skill, and with much more learning, than any other printer of that period. All that we have said on this point is fully corroborated by the account which he has himself given, in his preface to Aristotle's *Organon*, published in 1495, of the circumstances which induced him to undertake the publication of the Greek classics. The passage is thus translated by Mr Roscoe (*Life of Leo the Tenth*, vol. i., p. 110):—"The necessity of Greek literature is now universally acknowledged; insomuch that not only our youth endeavour to acquire it, but it is studied even by those advanced in years. We read but of one Cato among the Romans who studied Greek in his old age, but in our times we have many Catos; and the number of our youth who apply themselves to the study of Greek is almost as great as of those who study the Latin tongue; so that Greek books, of which there are but few in existence, are now eagerly sought after. But by the assistance of Jesus Christ I hope ere long to supply this deficiency, although it can only be accomplished by great labour, inconvenience, and loss of time. Those who cultivate letters must be supplied with books necessary for their purpose, and till this supply be obtained I shall not be at rest."

The *Editiones Principes* of the classics have always formed capital objects in bibliography, and are sometimes spoken of with a degree of rapture in bibliographical works, which is apt to appear inappropriate and unreasonable to those who value books solely as they are calculated to afford delight or information. The lover of first editions has, however, some plausible reasons to assign in justification of this expensive, and, as some think, factitious passion. These editions are valuable, in the first place, as curious monuments of early typography, and, in the next place, as more faithful representatives of the best ancient manuscripts than any other editions. *Earum editionum authoritatem*, says Maittaire, *aliis omnibus esse præferendam, quippe quæ sola MSS. fide nitatur*. This ground of preference, however, has some learned oppugners. Schelhorn, in his *Amœnitates Literariæ*, speaks of those to whom we are indebted for the first editions of the classics, as, in general, very ignorant men; quite incapable to collate manuscripts themselves, and seldom taking assistance from those who were. The first manuscript that could be procured, it has been said by others, and not that which, after a careful collation, appeared entitled to a preference, was hastily committed to the press, in order to take advantage of the recent discovery. Thus Grævius, in the preface to his edition of Cicero *De Officiis*, states, that the celebrated *editio princeps* of that work, by Fust, was printed from a very inaccurate manuscript.[2] On the other hand, there are many who view those editions in the same light with Maittaire. M. La Grange assures us, in the preface to his French translation of Seneca's works, that he never, in any case of difficulty, consulted the *editio princeps* of 1475, without finding there a solution of his doubts; adding generally, *que ceux qui studient les auteurs anciens, soit pour en donner des éditions correctes, soit pour les traduire dans une autre langue, doivent avoir sans cesse sous les yeux les premiers éditions de ces auteurs*. To the same purpose, M. Santander observes, that the *editio princeps* of Pliny the elder, printed at Venice by Spira in 1469, is in many places more accurate than the celebrated edition of Father Hardouin. The truth seems to be, that though many first editions have a real literary value, for such purposes as are specified by M. La Grange, there are others which have no value save what their extreme rareness gives them; that, therefore, they who scoff at, and they who laud indiscriminately, these literary rarities, are equally in the wrong; in a word, that we must apply a different rule of estimation to the first editions of an Aldus, and those of such printers as Sweynheim and Pannartz.[3]

---

[1] *Annales de l'Imprimerie des* ALDE, ou Histoire des trois MANUCE, et de leurs Editions, par A. G. Renouard, seconde édition, 3 tom. 8vo, Paris, 1825; and a third edition in 1834, in one volume. Renouard afterwards published a similar work on the family of the learned printers, Robert and Henry Stephens, *Annales de l'Imprimerie des Estiennes*, Paris, 1837, 2 vols. 8vo.

[2] See a curious chapter on *First Editions* in Marchand's *Histoire de l'Imprimerie*. He mentions, as a piece of extreme folly, that one hundred guineas had been paid for a copy of the first edition of Boccaccio; but if that price deserved such a censure, what epithet shall we bestow on the purchase of a copy at the Roxburgh sale for the enormous sum of L.2260? This unprecedented sum, the largest ever given for a single volume, was a factitious price; as the identical book was resold in 1819 for L.918, 15s., which, as Brunet truly remarks, "est encore un prix fort honnête."

[3] When Dr Dibdin tells us (*Introduction to the Classics*, v. AULUS GELLIUS), "that all the first editions printed by Sweynheym and Pannartz are considered as particularly valuable by the curious in bibliography," he should have added, chiefly on account of their great rarity, not on account of their accuracy.

Bibliography.

The classics have often been published in sets more or less complete, and more or less estimable for beauty, correctness, commentaries, and so forth. Lists of all these sets, with remarks on their relative extent and merits, will be found in the bibliographical works to be immediately mentioned. As the origin of the *Delphin* collection forms an interesting piece of literary history, it may not be improper to notice it more particularly. This celebrated body of Latin classics was originally destined for the use of the dauphin, son of Louis XIV., and was projected by his governor the Duke of Montansier. This nobleman, who, though a courtier and soldier, was both a philosopher and a scholar, had been in the habit of carrying some of the classics along with him in all his campaigns; and had often experienced impediments to their satisfactory perusal, from the recurrence of difficulties and allusions which could not be removed or explained without books of reference too bulky for transport on such occasions. It was in these circumstances that the idea first occurred to him of the great utility of a uniform edition of the principal classics, in which the text of each should be accompanied with explanatory notes and illustrative comments; and when he became governor to the dauphin, he thought that a fit opportunity to set on foot an undertaking calculated to prove so useful to the studies of the young prince. Huet, bishop of Avranches, then one of the dauphin's preceptors, was accordingly commissioned to employ a sufficient number of learned men for this purpose, and to direct and animate the undertaking. Once every fortnight they came to him on a stated day, each with the portion of his work which he had finished in the interval, to undergo his inspection and judgment. The copious verbal indexes, which constitute so valuable a portion of these editions, were added at his suggestion; but not without considerable opposition on the part of his assistants, who were appalled by the prospect of so much irksome labour as would be necessary to do justice to this part of the plan (*Memoirs of Huet's Life*, book v.). The collection, including Danet's *Dictionary of Antiquities*, extended to sixty-four volumes quarto. "It is remarkable," says Dr Aikin, in one of the notes to his excellent translation of *Huet's Memoirs*, "that Lucan is not among the number. He was too much the poet of liberty to suit the age of Louis XIV."—This extensive series of the Latin classics, enlarged with the notes of the Variorum editions, was republished at London, 1819-1830, by A. J. Valpy, forming in all 185 vols. 8vo.

The following may be noticed as among the most useful bibliographical accounts of the classics:—1. *A View of the various Editions of the Greek and Roman Classics, with Remarks*, by Dr Harwood. This work, first published in 1775, has gone through several editions; the larger works of the same kind, to which it gave rise, not having superseded it as a convenient manual in this department of bibliography. 2. *Degli Autori Classici, sacri e profani, Greci e Latini, Biblioteca portatile*, 2 vols. 12mo, Venice, 1793. This work was compiled by the Abbé Boni and Bartholomew Gamba, and contains a translation of the preceding, with corrections and large additions, besides criticisms on the works of bibliographers, and a view of the origin and history of printing. 3. *An Introduction to the Knowledge of Rare and Valuable Editions of the Classics*, by T. F. Dibdin, D.D. The first edition was published in 12mo in 1803; but it has since been greatly enlarged in the subsequent editions, the last of which, or fourth, appeared in 2 vols. in 1827. The utility of this work is considerably enhanced by the full account which it contains of Polyglot Bibles, of the Greek and Latin editions of the Septuagint and New Testament, and of lexicons and grammars. 4. *A Manual of Classical Bibliography*, by J. W. Moss, B.A., in 2 vols. 8vo, published in 1825. This useful work contains a full account of the translations of the classics, published in the different languages of Europe, with notices of critical and illustrative comments on the various classical authors. The prices obtained for the rarer editions at public sales are also specified.

Bibliography.

The improved editions, by Harles and Ernesti, of the *Bibliotheca Græca* and *Bibliotheca Latina* of Fabricius, are well known to the learned as immense magazines of information in regard to the classics and classical literature; but as they extend over a much wider field of inquiry than is embraced by bibliography, it does not belong to our present subject to give a more particular account of them.

V. *Of Anonymous and Pseudonymous Books.*

The great number of books published anonymously, as well as under false or feigned names, early directed the attention of the learned to this branch of bibliographical inquiry. In 1669 Frederick Geisler, professor of public law at Leipzig, published a dissertation *De Nominum Mutatione*, which he reprinted in 1671, with a short catalogue of anonymous and pseudonymous authors. About the same period a similar but more extensive work had been undertaken by Vincent Placcius, professor of morals and eloquence at Hamburg, and which was published in 4to in 1674, with this title—*De Scriptis et Scriptoribus, anonymis atque pseudonymis, Syntagma.* Four years thereafter John Decker, a learned German lawyer, published *Conjecturæ de Scriptis adespotis, pseudepigraphis, et suppositiitis*, which was republished in 1686, with the addition of two letters upon the same subjects, one by Paul Vindingius, a professor at Copenhagen, and the other by the celebrated Peter Bayle. In 1689 John Mayer, a clergyman of Hamburg, published a letter to Placcius under this title—*Dissertatio Epistolica ad Placcium, qua anonymorum et pseudonymorum farrago exhibitur.* Placcius meanwhile had continued his inquiries; and after his death the fruits both of his first researches and additional discoveries were embodied in one work, and published in a folio volume, at Hamburg in 1708, by Matthew Dreyer, a lawyer of that city. The work was now entitled *Theatrum Anonymorum et Pseudonymorum;* and, besides an Introduction by Dreyer, and a Life of Placcius by John Albert Fabricius, it contains, in an appendix, the before-noticed treatises of Geisler and Decker, with the relative Letters of Vindingius and Bayle, as well as Mayer's *Dissertatio Epistolica* addressed to Placcius. This very elaborate work contains notices of six thousand books or authors; but it is ill arranged, often inaccurate, and three-fourths of it are made up of citations and extracts, equally useless and fatiguing.[1]

A part of this subject, that relating to books published under false or fanciful names, had been undertaken in France by Adrian Baillet, nearly about the same period that Placcius commenced his inquiries. In 1690 this author published his *Auteurs Déguisés;* but this is little more than the introduction to an intended catalogue of such authors, which Baillet never completed; being deterred, as Niceron says, by the apprehension that the exposing of concealed authors might some way or other involve him in trouble. In this piece, which was reprinted in the sixth volume of De la Monnoye's edition of Baillet's *Jugemens des Savans*, there are some curious literary anecdotes, particularly those illustrative of the rage which prevailed after the revival of letters for the assumption of classical names. In Italy these names were so generally introduced into families, that the names of the saints, hitherto the common appellatives, almost disappeared from that country.

The taste for this species of research, which the work

[1] See the copious article on Placcius, in Chaufepié's *Nouveau Dictionnaire Historique et Critique*, tom. iii.

Bibliography.

of Placcius had diffused in Germany, produced several supplements to it in that country. In one published at Jena in 1711, under the name of Christopher Augustus Neumann, there is, besides the list of authors, a dissertation upon the question, Whether it is lawful for an author either to withhold or disguise his name? which question he decides in the affirmative. This work is entitled *De Libris anonymis et pseudonymis Schediasma, complectens observationes generales, et Spicilegium ad* PLACCII *Theatrum.* But the most considerable of these supplements was that published by John Christopher Mylius, at Hamburg, in 1740. It contains a reprint of the *Schediasma* of Neumann, with remarks, and a list of three thousand two hundred authors, in addition to those noticed by Placcius. The notices of Mylius, however, are limited to books in the Latin, German, and French languages.

The last, and by far the best work in this department, is the *Dictionnaire des Ouvrages Anonymes et Pseudonymes*, by M. Barbier, librarian to the late Emperor of France. A second edition, greatly enlarged, was published in four vols. 8vo. in 1822–27. It comprises a vast number of articles; but the plan does not extend to any English, German, or Italian works, except those which have been translated into the French language. A similar work by Vinc. Lancetti, *Pseudonima ouvero Tavole Alfabetiche de' nomi finti*, &c., was published at Milan, 1836, 8vo. Works of this class are more particularly useful in regard to the literary productions of periods and countries which have been greatly restricted in the liberty of the press.

VI. *Of Condemned and Prohibited Books.*

Books supposed hurtful to the interests of government, religion, or morality, have sometimes been condemned to the flames, sometimes censured by particular tribunals, and sometimes suppressed. Such methods of destruction have been followed in various countries, both with respect to their own productions and those of their neighbours. In some countries, lists of the books prohibited within them have from time to time been published; and in these lists are often found the most highly-prized productions of the literature of other nations. This constitutes, indeed, a melancholy portion of the history of books; for though the facts which it collects sometimes amuse by their folly, they oftener excite indignation and pity at the oppressions of power, and the sufferings of learning.

The practice of condemning obnoxious books to the flames is of very ancient date. The works of Protagoras of Abdera, a disciple of Democritus, were prohibited at Athens, and all the copies that could be collected were ordered to be burnt by the public crier. Livy mentions that the writings of Numa, found in his grave, were condemned to the flames, as being contrary to the religion which he had himself established. Augustus caused two thousand books of an astrological cast to be burnt at one time; and he subjected to the same doom some satirical pieces of Labienus. Tacitus mentions a work which the senate under Tiberius condemned to the fire for having designated Cassius as the last of the Romans.[1] This practice was early introduced into the Christian world. "After the spreading of the Christian religion," says Professor Beckmann, "the clergy exercised against books that were either unfavourable or disagreeable to them the same severity which they had censured in the heathens as foolish and prejudicial to their own cause. Thus were the writings of Arius condemned to the flames at the council of Nice; and Constantine threatened with the punishment of death those who would conceal them. The clergy assembled at the council of Ephesus requested Theodosius II. to cause the works of Nestorius to be burnt, and this desire was complied with. The writings of Eutyches shared the like fate at the council of Chalcedon; and it would not be difficult to collect examples of the same kind from each of the following centuries."

When the Popes prevailed upon the nations of Christendom to acknowledge their infallibility in all matters appertaining to religion, they also took upon themselves the care and the right of pointing out what books should or should not be read; and hence originated those famous *Expurgatory Indexes* which furnish such ample materials for the bibliography of prohibited books. There is a copious list of these *Indexes* in the work of Peignot, to be immediately noticed. The next step in the progress of usurpation was the licensing of books. By the council of Lateran, held at Rome in 1515, it was ordered that all books should, previously to publication, be submitted to the judgment of clerical censors. "To fill up the measure of encroachment," says Milton, "their last invention was to ordain that no book should be printed, as if St Peter had bequeathed them the keys of the press also as well as of paradise, unless it were approved and licensed under the hands of two or three gluttonous friars. Till then books were ever as freely admitted into the world as any other birth; the issue of the brain was no more stifled than the issue of the womb; no envious Juno sat cross-legged over the nativity of any man's intellectual offspring" (*Liberty of Unlicensed Printing*).

The following works contain accounts of condemned and prohibited books, and of the *Indices Expurgatorii*:—1. *Dissertatio historico-literaria de Libris Combustis*, in the seventh volume of Schelhorn's *Amœnitates Literariæ.* The same subject is resumed in the eighth and ninth volumes. 2. *Index generalis Librorum prohibitorum a Pontificis auctoritate; in usum Bibliothecæ Bodleianæ*, by Tho. James, 1627. 3. *FRANCUS De Papistarum Indicibus Librorum prohibitorum*, published at Leipzig in 1684. 4. *Thesaurus Bibliographicus ex Indicibus Librorum prohibitorum congestus*, published at Dresden in 1743. 5 *Dictionnaire Critique et Bibliographique des principaux Livres condamnés au feu, supprimés ou censurés*, par G Peignot, 2 vols. 8vo, Paris, 1806. This book is amusing, and gives a copious list of *Indices Expurgatorii*, as well as of authors who have treated of the subject of condemned books in general; but it cannot be allowed that it contains anything approaching to a complete enumeration of the *principal* works which come within the scope of the title-page. There are very few English books noticed, either those condemned in this country or those prohibited in others; though in this latter class the most valuable of our philosophical and literary works would be found. One of the most preposterous sentences of prohibition incurred by an English author is that mentioned in a letter from Sir John Macpherson, while in Spain, to Mr Gibbon; namely, that Smith's *Wealth of Nations* was prohibited there, "on account of the lowness of its style and the looseness of its morals" (Gibbon's *Posthumous Works*, vol. iii.).

We should like to see an accurate account of works which have been condemned to the flames, or suppressed, in Britain. This would include such works as Halle's *Chronicle*, prohibited by Act of Parliament in 1551; portions of Holinshed's *Chronicles*, castrated by order of Queen Elizabeth; Cartwright's *Admonition to Parliament*, suppressed by the English bishops in 1572; Stubbes' *Gaping Gulf*, 1579, for which he and the printer had their right hands cut off. In short, we should find some as abominable instances of oppression in this particular as ever disgraced the worst governments of continental Europe. The proceedings against Prynne, on account of his *Histriomastix* or *Player's Scourge*, furnish a noted example. We wish

[1] See the chapter on *Book Censors* in Professor Beckmann's *History of Inventions.*

Bibliography.

we could add, that these proceedings have always been mentioned by our historians in the terms which their singular atrocity is calculated to call forth from every heart that has one chord in unison with the rights of humanity. Prynne, who was by profession a lawyer, is characterized by Mr Hume as being a "great hero among the puritans." He was in truth a very fanatical person; but his learning was immense, his courage unconquerable, and his honesty certainly as great as that of any of his opponents or oppressors. His *Histriomastrix*, a quarto of upwards of a thousand closely printed pages, with all its margins studded with authorities, came out in 1633, and was intended to decry all dramatic amusements and all jovial recreations, and to censure the lax discipline and the Popish ceremonies of prelacy. In the alphabetical table at the end of the volume there is a reference in these words—"*Women actors, notorious whores;*" and as the queen sometimes took a part in the dramas played at court, it was alleged that Prynne pointed at her majesty in this reference, and that the book was in fact intended as a satire upon the government. He was accordingly prosecuted in the Star-Chamber for a libel. The book (which the judges described as a huge misshapen monster, in the begetting of which the devil must have assisted) was condemned to be burned; and, after the example of foreign countries, this was ordered to be done, for the first time in England, by the hands of the hangman. It was ordered that Mr Prynne should be expelled from Oxford, he being a graduate of that university; and also from the bar. He was further sentenced to pay a fine of L.5000, and to endure perpetual imprisonment: but this was not all; he was condemned to stand in the pillory on two successive days, in Westminster and Cheapside, there, on each day, to have an ear cut off. One of the judges, who represented the queen's virtues as such that neither oratory nor poetry could do anything like justice to them, was for making the fine L.10,000; stating that he knew it was much more than Mr Prynne was worth, yet far less than he deserved to pay; and expressed a further wish, that his nose should be slit, and his forehead burned, in addition to the loss of his ears, because he might buy himself a periwig, and so hide that loss.[1] The book, which involved its author in such unprecedented calamities, had actually been licensed, according to the regulations which then obtained; but it was stated that the licenser had not read the whole of it. Well might Sir Simonds D'Ewes speak of this as a terrifying trial. "Most men," says he, "were affrighted to see that neither Mr Prynne's academical nor barrister's gown could free him from the infamous loss of his ears; and all good men conceived this would have been remitted; many asserted it was, till the sad execution of it. I went to see him a while after," continues Sir Simonds, "in the Fleet, to comfort him; and found in him the rare effects of an upright heart, by his serenity of spirit and cheerful patience."[2] Another memorable instance of persecution by the Star-Chamber, in the reign of Charles the First, was the case of Dr Alexander Leighton (father of Archbishop Leighton), for his two works—*The Looking Glasse of the Holy War*, 1624, 4to; and his *Zion's Plea against the Prelacy*, 1628, 4to. See art. LEIGHTON.

VII. *Of Bibliographical Dictionaries and Catalogues.*

The works which fall to be considered under this section, sometimes called *Dictionaries*, sometimes *Catalogues*, and sometimes *Bibliothecæ*, constitute the most generally useful and interesting class of bibliographical publications. By showing what has been written in all the various branches of human knowledge in every age and country, they act as useful guides to the inquiries of every class of the learned; while, by pointing out the differences of editions, they constitute manuals of ready information to the professed bibliographer.

Bibliography.

Works of this class are called *general* or *particular*, according as their object is to indicate books in all, or in one only, of the departments of science and literature. The former only aspire to point out rare or remarkable books; for no attempt has yet been made, or probably ever will be made, to compile a universal Bibliographical Dictionary. On the other hand, it is the object of *particular* dictionaries to notice all, or the greater part, of those books which have been published on the subjects which they embrace; and hence their superior utility to such as are engaged in the study of any particular science or subject.

The works of the former class which chiefly demand our notice are the following:—1, *Bibliographie Instructive, ou Traité de la Connoissance des Livres rares des singuliers*, par G. F. de Bure; in seven volumes octavo, published at Paris between 1763 and 1768. The books described in this work are arranged, in appropriate sub-divisions, under the five grand classes of *Theology*, *Jurisprudence*, *Sciences* and *Arts*, *Belles Lettres*, and *History*; and the classification which it exemplifies is that generally followed by foreign bibliographers. The names of the authors in all these classes are arranged alphabetically in the last volume; but it has no index to anonymous works, a want, however, which was afterwards supplied by another hand, in a thin octavo volume published in 1782, entitled *Bibliographie Instructive, tome dixième.* This is called the tenth volume, because De Bure had himself published a supplement of two volumes in 1769. Its title is, *Supplément à la Bibliographie Instructive, ou Catalogue des Livres de Louis Jean Gaignat.* De Bure was a bookseller at Paris, of great eminence in his profession, but still more distinguished for extensive information in all matters appertaining to bibliography and literary history; and, accordingly, his work is still the delight of bibliographers, though it has been followed by others which indicate a much greater number of books, and which also in some particulars excel it in accuracy. 2. *Dictionnaire Typographique, Historique, et Critique, des Livres rares, estimés et recherchés en tous genres*, par J. B. L. Osmont, 2 vols. 8vo, Paris, 1768. This work is more ample in notices of Italian books than that of De Bure. 3. *Dictionnaire Bibliographique*, 3 vols. 8vo, Paris, 1790. This work, generally known under the name of Cailleau's *Dictionary*, was compiled, according to M. Barbier and others, by the Abbé du Clos. It was republished in 1800, with a supplementary volume, by M. Brunet. It has been already mentioned that the third volume has a separate alphabet for anonymous books. 4. *Manuel du Libraire et de l'Amateur de Livres; contenant*, 1°, *Un nouveaux Dictionnaire Bibliographique;* 2°, *Une Table en forme de Catalogue Raisonné*, par J. C. Brunet. This comprehensive and extremely useful work was first published in three volumes 8vo, in 1810. A third edition, much enlarged, appeared in 1820, in 4 vols. 8vo. It contains a much greater proportion, both of English and of German books, than any of the preceding compilations, and its plan is such as to afford all the advantages both of a dictionary and a classed catalogue, three of the volumes being employed to indicate books under their names in alphabetical order, and the fourth to class them, divested of all bibliographical details, according to the system generally followed. The prices of the rarer editions are given from the principal sales that have taken place in France and other countries; so that, upon the whole, this work, though it has less literary interest than that of De Bure, is probably the best bibliographical dictionary extant for the purposes of the professed bibliographer. In 1836 Brunet published in three

Bibliography.

additional volumes *Nouvelles Recherches;* and a pirated edition of the two works incorporated into one alphabet, having appeared at Brussels, the author himself republished his *Manuel* in an enlarged and handsome edition at Paris, 1842, in 5 vols. large 8vo. This work is not likely to be soon superseded. F. A. Ebert's *Allgemeines Bibliographisches Lexicon*, Leipzig, 1821–30, 2 vols. 4to, is also a most useful book of reference. An English translation of it was printed at Oxford, 1837, 4 vols. 8vo.

In the class of *general* bibliographical dictionaries we must also place the following work, though its limitation to books in the learned and eastern languages renders it much less general in its plan than those we have described. It is entitled *A Bibliographical Dictionary, containing a Chronological Account, alphabetically arranged, of the most curious and useful books in all departments of Learning, published in Latin, Greek, Hebrew, Arabic, and other Eastern Languages.* It was published in 1803, by Dr Adam Clarke, in six volumes duodecimo. To the principal works noticed in this dictionary, there are added biographical notices and criticisms; but the author would have judged more wisely had he included books in the modern languages, instead of deviating so largely, and with but small pretensions to novelty, into the provinces of biography and general criticism. The supplement, which he published in two duodecimo volumes in 1806, under the title of *The Bibliographical Miscellany*, contains, among other matters, an account of English translations of the classics, and theological writers; a list of the cities and towns where printing was established in the fifteenth century; and a list of authors on literary history and bibliography. The work by Dr Robert Watt of Glasgow, so well known as the *Bibliotheca Britannica, or General Index of British and Foreign Literature*, published in 1824, 4 vols. 4to, merits great commendation as a most laborious and useful compilation. It is divided into two parts, in which authors and subjects are specified alphabetically. The plan is not very judicious, and being formed more from printed catalogues than actual examination of the books and editions, it was impossible to avoid endless mistakes; but its usefulness for reference is universally acknowledged. An American work, not yet completed, by S. Austin Allibone, promises to be one of great utility: its title, *A Critical Dictionary of English Literature, and British and American Authors to the middle of the present Century*, in one volume, royal 8vo.

The *Bibliographer's Manual of English Literature*, by W. T. Lowndes, in 4 vols. 8vo, 1834, is indispensable to a collector. For a first attempt of the kind, it displays a singular degree of accuracy and research. He had commenced another work, in which he proposed to give a minute and digested *classed Catalogue* of books connected with English literature as printed in Great Britain, as the *British Librarian or Book Collector's Guide*, 1839. He survived only to complete six numbers of the division, *Religion and its History*, which cannot but excite regret to find such a scheme to have been left unfinished. An early attempt of the kind by Andrew Maunsell, *Catalogue of English Books*, printed at London, 1595, folio, in two parts, contains the titles of many books now lost or forgotten.

The number of dictionaries and catalogues applicable to *particular* departments or provinces of learning, is much too great to permit us to do any thing more than to point out a few of them. For theology, we have Le Long's *Bibliotheca Sacra*, 1723, 2 vols. folio; and the edition by Masch, 1778, 4 vols. 4to, but never completed; Orme's *Bibliotheca Biblica*, 1824; and *Cyclopædia Bibliographica; a Library Manual of Theological and General Literature*, by James Darling, 1854, royal 8vo. This latter work is proposed to be accompanied with a separate volume of subjects, the former being a volume of authors. Lipenius, a learned German divine and professor, born in 1630, and who died in 1692, worn out, as Niceron says, by labour and chagrin, compiled a *Bibliotheca Theologica*, a *Bibliotheca Juridica*, a *Bibliotheca Philosophica*, and a *Bibliotheca Medica*, making in all six volumes folio. The *Bibliotheca Juridica* has been several times reprinted, and various supplements have been added to it by Schott and Senkenberg, published at Leipsic in 1775 and 1789; and by Madinh, at Breslau, 1816-20. An immense number of books are indicated in each of these *Bibliothecæ* of Lipenius; of all of which the plan is to arrange the books alphabetically according to their subjects; each *Bibliotheca* having also an alphabetical table of the names of the authors whose works are arranged under the alphabet of subjects. The *Bibliotheca Juridica*, owing to the corrections and additions which it has received, forms by much the most valuable part of this series. In regard to jurisprudence, we may further mention Bridgman's *Legal Bibliography;* and the valuable work of M. Camus, entitled *Lettres sur la profession d'Avocat; et Bibliothèque choisie des Livres de Droit.* Among other works of particular bibliography, a few others may be selected as worthy of special notice:—Wolfius' *Bibliotheca Hebraica*, 1715-33, 4 vols. 4to; Walchius's *Bibliotheca Theologia Selecta*, 1757, 4 vols. 8vo; and his *Bibliotheca Patristica*, new edition, 1834, with Fürst's *Bibliotheca Judaica*, Leipzig, 1851. Backer's *Bibliothèque des Ecrivains de la Compagnie de Jesus*, may be considered as an improvement upon Ziegelbauer's great work. There are some truly excellent catalogues of works in the sciences and in natural history. Such are Dr Young's *Catalogue of Works relating to Natural Philosophy and the Mechanical Arts*, annexed to his *Lectures on Natural Philosophy;* the *Bibliotheca Mathematica* of Murhard; the *Bibliographie Astronomique* of La Lande; and the *Catalogus Bibliothecæ Historiæ Naturalis Josephi Banks*, by Dr Dryander, which, though the title seems to promise only the catalogue of a private library, is allowed to furnish the most complete and best arranged view of books in natural history ever published in any country. In the great department of history there have been published various *Bibliothecæ*, some of them embracing the historical works of all ages and nations; others, those only which relate to particular countries. The *Bibliotheca Historica* of Meusel, an immense work, is of the former class. It includes voyages and travels; but of books of this class there is an excellent separate catalogue in 6 vols. 8vo, by M. Boucher de la Richarderie. *Bibliothèque Universelle des Voyages*, published at Paris in 1808. We must observe, however, that this work would have been better suited to the legitimate ends of such a compilation had the author confined himself to bibliographical notices, and wholly refrained from those long extracts by which his book has been so much enlarged. Of the class of *Bibliothecæ* applicable to the history of particular countries, the *Bibliothèque Historique de la France*, originally published in 1719, in 1 vol. folio, but in the last edition, published between 1768 and 1778, extended to five volumes, is by far the most splendid and perfect example. It contains nearly fifty thousand articles, as well manuscript as printed, methodically arranged under the different heads of French history to which they relate, and accompanied with a complete set of indexes to authors and subjects.

We must refer such of our readers as are desirous of seeing a fuller list of catalogues of books in the different branches of knowledge before 1812, to the *Répertoire Bibliographique Universel* of M. Peignot, a useful but ill arranged work

In England many useful works of particular bibliography might be specified. Such, for instance, as Gough's *British Topography*, 1780, 2 vols. 4to; Upcott's *Bibliographical Account of the principal Works relating to English Topography*, 1818, 3 vols. 8vo; the *British Librarian* of Oldys, 1740; the *Librarian* of Savage, 1808, 3 vols. 8vo; Baker and Reed's *Biographia Dramatica*, by Jones, 1812, 4 vols. 8vo; Arch-

Bibliography.

deacon Cotton's *Editions of the Bible and parts thereof in English*, second edition, 1852; and the Rev. Christopher Anderson's *Annals of the English Bible*, 1845, 2 vols. 8vo. Various bibliographical works relating to separate English counties might also be noticed.

Querard's *La France Littéraire, ou Dictionnaire Bibliographique*, &c., in 10 vols., and the new series, not yet completed, are works of great value. We may also mention Nisard's *Histoire des Livres Populaires, ou de la Littérature du Colportage*, 1854, 2 vols. 8vo, as a curious and amusing work. Oettinger's *Bibliographie Biographique*, contains exclusively a catalogue of biographical publications.

In foreign literature, it might be easy to enumerate various other important works. Such, for instance, as Haym's *Biblioteca Italiana*, 2 vols. 4to, or 4 vols. 8vo; Worm's *Danske, Norske og Islandske Lærde Lexicon*, 1771–84, 3 vols. 8vo; Nyerup and Kraft's *Almindeligt Litteratur Lexicon*, &c., 1820, 2 vols. 4to; Georgj's *Allgemeines Europäisches Bucher-Lexicon*, 1742–58, folio; Jöcher's *Allgemeines Gelehrten-Lexicon*, 1750, 4 vols. 4to; and Kayser's *Neues Bücher-Lexicon*, from 1750; with the continuations, by Zuchold, to 1852, still in the course of publication.

VIII. *Of the Classification of Books.*

The classing of books in a catalogue, so as to furnish a systematic view of the contents of an extensive library, is a task of much difficulty and importance. In order to this, it is necessary to refer every book to its proper place in the general system of human knowledge; and to do so with precision, it is necessary to have clear and exact ideas of the scope and objects of all the departments and branches of which that system consists. The utility of catalogues so classed is very great, and consists obviously in this, that the books upon any subject are found at once by referring to the proper head. All who duly consider the matter, therefore, must concur in Dr Middleton's brief and emphatic description of such an undertaking, as *res sane magni momenti, multique sudoris*.[1]

Whether classed catalogues were in use among the ancients is a piece of information which has not descended to us. The first who is known to have written on the subject was a German, named Florian Treffer, who, in 1560, published, at Augsburg, a method of classing books. Cardona in 1587, and Scholt in 1608, published treatises upon this subject; and, in 1627, Gabriel Naudé, a writer of no small celebrity in his day, published his *Avis pour dresser une Bibliothèque*, in which he treats of the principles of classification. A translation of this little work by John Evelyn, *Instructions concerning erecting a Library*, was dedicated to the Earl of Clarendon, Lord High Chancellor, in 1661. The catalogue which Naudé compiled of the library of the Canon de Cordes, afterwards purchased by Mazarin, was published in 1643, and is esteemed a curiosity among bibliographers. In the early part of the eighteenth century, Gabriel Martin, a learned Parisian bookseller, who seems to have been much employed in compiling catalogues, chalked out a system of arrangement, which in a great degree, superseded all others, and, in its leading divisions, is still generally followed on the Continent. Various other systems have, however, been proposed by the bibliographers of France and Germany; but, before proceeding to any particular notice, either of the system of Martin or of those which differ from it, we must observe, that all who have written upon the subject seem to have confounded two things, as we think, perfectly distinct,—the arrangement to be followed in the catalogue of a library, and that to be followed in placing its books. They all suppose the same nicety and exactness of classification to be equally necessary and equally practicable in both. Now, we must remark, that where there is a classed catalogue, the grand objects of a systematic arrangement are sufficiently provided for, independently of the location of the books; and if there should not be a classed catalogue, it seems very clear that the bulk of those who frequent a public library could derive little if any benefit from an accurate classification of books on the shelves, even supposing it practicable to effect and maintain it. The chief end of any arrangement to be effected on the shelves ought to be to aid the memories and abridge the labour of the librarians; and all that is useful in this respect may be accomplished by means of a much ruder plan than could be tolerated in any catalogue pretending to classification.

Bibliography.

The system generally followed, as we have already mentioned, is that of Martin, which divides books into the five great classes of *theology, jurisprudence, sciences and arts, belles lettres*, and *history*. Each of these classes has divisions and subdivisions more or less numerous, according to the number of the branches to be distinguished; and it is in the distribution of these that the chief differences are found in foreign catalogues; though the divisions and subdivisions of De Bure, as exemplified in his *Bibliographie Instructive*, are those commonly followed. Some bibliographers, however, have proposed to alter the order, others to diminish, and some to increase the number of the primitive classes. M. Ameilhon, in a paper published in the *Memoirs* of the French Institute, proposes the following leading divisions,—grammar, logic, morals, jurisprudence, metaphysics, physics, arts, belles lettres, and history.[2] In this arrangement, *theology*, to which he has great objections as a separate class, is transferred, with evident impropriety, to the class of *metaphysics*. M. Camus has also investigated the principles according to which books ought to be classed, in another paper in these *Memoirs*, already quoted; but as he has not reduced his method, which proceeds on views much too fanciful for the purpose, to specific heads, we can only refer our readers to his paper. Equally remote from the proper objects of a classed catalogue are the systems proposed by M. Peignot and by M. Thiebaut.[3] The former takes the well-known speculations of Bacon and D'Alembert, as to the genealogy of knowledge, for the basis of his system, and thus fixes upon three principal heads or classes, under the names of history, philosophy, and imagination, with the addition of bibliography as an introductory class. In the system of the latter, there are, in like manner, only three principal heads, founded upon a division of knowledge, into instrumental, essential, and suitable.

Germany also has produced a variety of bibliographical systems, some of them as absurdly refined as those just mentioned; whilst others, as, for example, that of Leibnitz, are better adapted to practical purposes. The classes proposed by this eminent philosopher are as follows,—theology, jurisprudence, medicine, intellectual philosophy, mathematics, natural philosophy, philology, history, and miscellanies.[4] Another system, not very remote from this, is that of M. Denis, formerly keeper of the Imperial Library at Vienna, in which books are divided into the classes of theology, jurisprudence, philosophy, medicine, mathematics, history, and philology. This system is developed in his *Introduction to the Knowledge of Books*, to be afterwards described.

Dr Middleton is the only British author of name who has written any separate tract on the classification of books. The classes proposed by him are these,—theology, history, jurisprudence, philosophy, mathematics, natural history, medicine, belles lettres (*literæ humaniores*), and miscellanies.

[1] See his very judicious tract, entitled *Bibliothecæ Cantabrigiensis ordinandæ Methodus*, in the fourth volume of his works.

Bibliography.

His object in the tract referred to was to recommend the adoption of this arrangement for a catalogue of the university library of Cambridge; and, whatever may be its defects, it cannot be questioned that a printed catalogue of an extensive collection, so classed, would have proved of eminent utility.

Naudé mentions a writer who proposed to class all sorts of books under the three heads of morals, sciences, and devotion; and who assigned, as the grounds of this arrangement, these words of the psalmist, *Disciplinam, Bonitatem, et Scientiam doce me.* All such systems as those of M. Peignot and M. Thiebaut, when applied to the formation of catalogues, appear to us quite as absurd as this system deduced from the psalmist. The remark which Naudé applied to it, that it seemed intended "to crucify and torture the memory by its subtilities," is just as applicable to the former. That system, he adds, "is the best which is most facile, the least intricate, and the most practised; and which follows the faculties of theology, physic, jurisprudence, mathematics, humanity, and others."[1] M. Ameilhon also objects strongly to all over-refined bibliographical systems, and particularly to those which aspire to follow the genesis and remote affinities of the different branches of knowledge. "L'exécution," says he, "en seroit impossible; ou si elle ne l'étoit pas au moins entraineroit-elle des difficultés, qui ne pourroient être surmontées que par des hommes profondément réfléchés et exercés aux méditations métaphysiques."[2] The truth is, that when bibliographers speculate in this field with a view to catalogue-making, they entirely forget their proper province and objects. They have nothing whatever to do with genealogical trees of knowledge, or with any mode of classing books which is founded upon remote and subtile abstractions. The whole use and end of a classed catalogue is to furnish a ready index to books, arranged according to their subjects; and that arrangement is therefore to be preferred which is founded upon the most obviously marked and generally recognised divisions of those subjects. We may add, that to compile a good catalogue of an extensive library, even on this humbler plan, would require more learning and more correctness of knowledge and thinking, than are likely to be often employed in such an undertaking.

Though we are not altogether satisfied with the division and order of the classes in the system commonly followed, we have no doubt that, by means of an additional class, and a correct arrangement of the subdivisions, a catalogue might be formed perfectly adequate to every useful purpose. We allude to a class, such as is partly indicated in the schemes both of Leibnitz and Middleton, for the reception of works and collections which cannot with propriety be limited to any one division of knowledge. M. Camus thinks that works of this kind may be properly enough entered in the class in which their authors most excelled; those of Cicero, for example, among the Orators;[3] but, not to mention the evident incongruity of placing a collection so multifarious as Cicero's works under *Oratory*, there may sometimes be room for uncertainty as to the division under which, according to this rule, an author's works ought to be sought. These incongruities and inconveniences, together with those which must arise from placing Encyclopædias and general collections under any of the common divisions, can only be remedied by a *Miscellaneous Class;* and, while this class ought to indicate, in one of its divisions, the collective editions of an author's works, his separate treatises ought to be entered under the subjects to which they belong; as without this, the classed catalogue will not fully answer its purpose,—that of showing what has been written by the authors specified in it, on the different branches of knowledge. Thus, a catalogue compiled upon this plan would not only be rendered more consistent in its arrangement, but much more complete as an index to the materials of study.

Bibliography.

IX. *Of Bibliography in general.*

It was our object in this article to institute such a division of the subject as should enable us to point out the best sources of information in regard to all its branches; and in order to complete our view, we have still to notice some of those works which treat generally of all matters appertaining to bibliography. We do not know any book that presents a well-written, judicious, and comprehensive digest of these matters; but there are several which contain much curious and useful information in regard to them. 1. *The Introduction to the Knowledge of Books* (*Einleitung in Bucherkunde*), by M. Denis, whose supplement to Maittaire, and bibliographical system, we have already mentioned, is of this description. The last edition, published at Vienna in 1796, consists of two volumes quarto. It has never been translated from the original German; and it is to be observed, that though it treats of the substances, forms, and classification of books, it cannot be considered as a merely bibliographical work, a large portion of it being devoted to the general history of learning. The author, who was long principal librarian of the Imperial Library at Vienna, died in 1808. 2. *Manuel Bibliographique*, ou Essai sur la connoissance des livres, des formats, des éditions, de la manière de composer une Bibliothèque, etc.; par G. Peignot. Published in 1800. 3. *Dictionnaire raisonné de Bibliologie*, contenant l'explication des principaux termes relatifs à la Bibliographie; des notices sur les plus célèbres Bibliographes; et l'exposition des différens Systèmes Bibliographiques, 3 vols. 8vo, by the same author. Bibliography is certainly indebted to this industrious compiler; but his vague notions of its objects and rank have too often led him into confusion and extravagance. 4. *Cours de Bibliographie, ou la science du Bibliothécaire*, par C. F. Achard, 3 vols. 8vo, published at Marseilles in 1807. The chief value of this compilation consists in its details of the different systems which have been proposed for classifying books. We learn from the introduction, that M. François de Neufchâteau, when minister of the interior, orders the librarians of all the departments to deliver lectures on bibliography; but that the plan, which indeed savours somewhat of *bibliomania*, entirely failed, these librarians having been found quite incapable of prelecting upon their vocation. 5. *Introduction to the Study of Bibliography; to which is prefixed a Memoir on the public Libraries of the Ancients*, by Thomas Hartwell Horne, 2 vols. 8vo, published at London in 1814. This is chiefly translated and compiled from the French bibliographical works, and will be found useful to those who have not access to them. It contains full lists of writers on bibliography and literary history, and the fullest account we have seen of catalogues of libraries both British and foreign. The specimens of early typography, and of the vignettes and monograms of the early printers, are neatly executed. 6. Namur, *Manuel du Bibliothécaire*, published at Bruxelles, 1834, 8vo; also, 7, by the same author, *Bibliographie Paléographico-Diplomatico-Bibliologique Générale*, Liege, 1838, 2 vols. 8vo. 8. *The Library Companion, or the Young Man's Guide, and the Old Man's Comfort, in the Choice of a Library*, by that most enthusiastic, but not the most judicious of bibliographers, the Rev. Dr Dibdin, 1824, 8vo, may close this list; along with his well-known *Bibliomania*, 1811; his *Bibliographical Decameron*, 1817, 3 vols.; his *Bibliographical Antiquarian and Picturesque Tour in France and Germany*, 1821, 3 vols.; and his similar *Tour in the Northern Counties of*

[1] Evelyn's Translation of Naudé's *Avis pour dresser une Bibliothèque.*

[3] *Ibid.*, tom. i.

Bibliomancy || Bichât.

England, and in Scotland, 1838, 2 vols.; the three latter works, each in royal 8vo, being printed and illustrated in a most sumptuous manner.

Bibliography certainly presents a pretty wide field of inquiry, and in which there is yet room for useful works; but it must appear evident, from the details contained in the present article, that this field has in almost every part been long cultivated; if not always with perfect taste and judgment, yet with great industry, and so as to yield very profitable returns to the commonwealth of learning.

Bichât.

BIBLIOMANCY (*βίβλος* and *μαντεια*), a kind of divination performed by means of the Bible; otherwise called *sortes biblicæ* or *sortes sanctorum*. It consisted in selecting passages of Scripture at hazard, and thence drawing indications concerning the future. It was much used at the consecration of bishops.

BIBLIOTHECA (*βιβλιοθήκη*), a library or place for books. It is also applied to a treatise giving an account of all the works on a particular subject.

BICE, or BISE, among painters, a blue colour prepared from the lapis Armenus, or calcareous salt of copper. It bears the best body of all bright blues used in common work, but is the palest in colour.

BICESTER, or BISSETER, a very neat town, in the county of Oxford, fifty-five miles from London, containing several handsome residences. The church is a large structure with a lofty tower. A small stream here runs into the Cherwell at Islip. The market is held on Friday. It has no other trade than the supply of the agricultural district which surrounds it. Pop. in 1851, 2763.

BICHAT, MARIE-FRANÇOIS-XAVIER, a celebrated French anatomist and physiologist, was born at Thoirette in the department of Ain, in 1771. His father, who was himself a physician, initiated him at an early age in those studies which were to prepare him more particularly for the profession to which he had destined him. He studied first at the college of Nantua, and afterwards at Lyons; and was early distinguished for his activity of mind and facility in acquiring knowledge. In mathematics, and the physical sciences more especially dependent on abstract reasoning, he made rapid progress. He afterwards became passionately fond of natural history, and devoted all his time to this new study; but his ardour was suddenly checked by the reflection that he was engaged in pursuits that were boundless in their object, and might lead him too far from his future profession, through which alone he aspired to celebrity. Bidding adieu, therefore, to his favourite occupations, he devoted himself to the study of anatomy and surgery, under the guidance of Petit, chief surgeon to the Hôtel Dieu at Lyons. Some time after he had fully engaged in this course of instruction, he was unable to resist his passion for mathematics, and he resumed his early studies, restricting himself however within such limits as did not interfere with his medical pursuits. Petit soon discerned the superior talents of his pupil; and, although the latter had scarcely attained the age of twenty, employed him constantly as his assistant in his professional labours. The revolutionary disturbances compelled Bichât to fly from Lyons and take refuge in Paris about the end of the year 1793. He there resumed his studies, and became a pupil of the celebrated Dessault; and after no long time his companion and his friend. The merit of Bichât was brought to the notice of Dessault by an accidental circumstance. It was the custom in the school, that the substance of the lecture of the preceding day should be recapitulated, as an exercise, before the whole class, by one of the pupils selected for this purpose: and one day when the pupil on whom this task devolved was absent, the professor asked if any one among his auditory would supply his place. Bichât volunteered his services, and acquitted himself to the admiration of all his hearers. Dessault, in particular, was strongly impressed with the superiority of his genius; and from that day Bichât became an inmate in his house, and was treated as an adopted son. Between the years 1793 and 1795 he actively participated in all the labours of Dessault. Notwithstanding these multiplied occupations, Bichât found means to prosecute his own researches in anatomy and physiology, to which he devoted every interval of leisure he could seize. The sudden and untimely death of Dessault was a severe blow to Bichât, but did not eventually relax his efforts. His first care seems to have been to acquit himself of the obligations he owed his benefactor, by contributing to the support of his widow and her son; and by conducting to a close the fourth volume of Dessault's *Journal de Chirurgie*. To this volume he subjoined a biographical memoir of its author, in which he pays a just tribute to his merit. His next object was to re-unite and digest in one body the different surgical doctrines which Dessault had advanced in fugitive papers, published in various periodical works. Of these he composed, in 1797, a work in two vols. 8vo, entitled *Œuvres Chirurgicales de Dessault, ou Tableau de sa Doctrine, et de sa Pratique dans le Traitement des Maladies Externes;* a work in which, although he professes only to explain the ideas of another, he develops them with the clearness and copiousness of one who is a perfect master of the subject. He was now at liberty to pursue the full bent of his genius, and soon arrived at those comprehensive and masterly views of physiology, by which eventually he gained so much reputation. Undisturbed by the storms which agitated the political world, he pursued with steadiness the course he had meditated, and directed his more immediate attention to surgery, which it was then his design to practise. We meet with many proofs of his industry and success at this period in the *Recueil de la Société Médicale d'Emulation*, an association of which Bichât was one of the most zealous and active members. Three memoirs which he communicated were published by the society in 1796; the first describing an improvement in the instrument for trepanning; the second a new process for the ligature of polypi; and the third, the distinction to be observed in fractures of the clavicle, between those cases requiring the assistance of art, and those in which its interference would be of no avail. In 1797 Bichât commenced a course of anatomical demonstrations. He had hired a small room for the purpose; but his merit as a teacher soon attracting a crowd of auditors, he was obliged to enlarge his theatre, and was also encouraged to extend the plan of his lectures, and to announce what had never hitherto been attempted by one so young and inexperienced, a course of operative surgery. The boldness of the enterprise was equalled only by its success. Bichât's reputation was now fully established, and he was ever after the favourite teacher with the students who resorted to the capital. In the following year, 1798, he gave, in addition to his course on anatomy and operative surgery, a separate course of physiology. A dangerous attack of hæmoptysis interrupted for a time these heavy labours; but the danger was no sooner passed than he plunged into new engagements with the same ardour as before. He had now scope in his physiological lectures for a fuller exposition of his original views in the animal economy, which immediately excited much attention in the medical schools at Paris; and he was induced to publish them in a more authentic form. Sketches of these doctrines were given by him in three papers contained in the Memoirs of the *Société Médicale d'Emulation*. The doctrines contained in these memoirs were afterwards more fully developed in his *Traite sur les Membranes*, which appeared in 1800,

Bichât.

and which immediately drew the attention of the medical world both at home and abroad. Some time previous to this he gave to the public a small work, in which he endeavoured to give, in a condensed form, the lessons of Dessault relative to the diseases of the urinary passages. In the notes to this volume we may perceive the germ of many of those views which were peculiar to Bichât.

His next publication was the *Récherches Physiologiques sur la Vie et sur la Mort*, in 1800, which consists of two distinct dissertations. In the first, he explains, at greater length than he had previously done, his classification of functions, and traces the distinction between the animal and organic functions in all its bearings. In the second, he investigates the connection between life and the actions of the three central organs, the heart, lungs, and brain. But the work on which he bestowed the most attention, and which contained the fruits of his most profound and original researches, is the *Anatomie Générale*, which was published in in four volumes octavo in 1801.

Before Bichât had attained the age of eight-and-twenty, he was appointed physician to the Hôtel Dieu, a situation which opened an immense field to his ardent spirit of inquiry. In the investigation of diseases, he pursued the same method of diligent observation and scrupulous experiment which had characterized his researches in physiology. He learned their history, not from books, but by studying them at the bedside of his patients, and by accurate dissection of their bodies after death. He engaged in a long series of examinations, with a view to ascertain the exact changes induced in the various organs by diseases, which he conceived, in every instance, primarily to affect some one of their constituent textures, while the rest did not suffer any change, unless by the supervention of some other disease. In the prosecution of these inquiries he had, in less than six months, opened above six hundred bodies. As intimately connected with the practical exercise of the healing art, he was anxious also to determine, with more precision than had hitherto been attempted, the effects of remedies on the body; and eagerly availed himself of the opportunities which his new appointment afforded him, of instituting a series of direct experiments on a very extensive scale. He began by giving singly different medicinal substances, and then watching attentively the phenomena that ensued. He then united them in various ways, first joining two together, then three, and so proceeding to more complicated combinations; and observed the particular changes in their mode of operating which resulted from their being thus combined. So wide a range of experiments, it is evident, could not have been conducted without assistance; and he selected forty of his young pupils to aid him in collecting the requisite observations. He had already, in this way, procured a vast store of valuable materials for his course of lectures on the Materia Medica, the completion of which was unfortunately prevented by his untimely death; but a great part of the facts were subsequently published in the inaugural dissertations of his pupils. Latterly, he had also occupied himself with framing a new classification of diseases.

During these arduous vocations, he never lost sight of his anatomical pursuits, and had commenced a new work on the subject, in which the organs were arranged according to his peculiar classification of their functions, under the title of *Anatomie Descriptive*. He lived only to publish the first two volumes of this work. It was, however, continued on the same plan, and completed in three volumes more, by MM. Buisson and Roux, who had been his most active assistants, and who appear to have been perfect masters of his ideas on the subject. His death was brought on by a fall from a staircase at the Hôtel Dieu; and although the accident did not at first appear to be serious, it excited so great a degree of fever, that his frame, already exhausted by excessive labour, and enfeebled by constantly respiring the tainted air of the dissecting-room, in which he had latterly passed the greater part of his time, sunk under the attack. He died on the 22d July 1802, universally regretted by his pupils, and attended to the last by the widow of his benefactor, from whom he had never been separated. Every tribute of respect was paid to his memory; his funeral was attended by above six hundred of his pupils, and by a number of the physicians in Paris. His bust, together with that of Dessault, was placed at the Hôtel Dieu by order of the first consul, in joint commemoration of the man under whose fostering protection so bright a genius was first brought before the public, and of the pupil who nobly emulated the fame of so great a master. (P. M. R.)

Bidal ‖ Biddle.

BIDAL, or BIDALE (*bid* and *ale*), in England, the invitation of friends to drink ale at some poor man's house, and there to contribute for his relief,—an ancient and still a local custom.

BIDASOA, or VIDASOA, a small river which rises in the Western Pyrenees, in the valley of Baztan, and flows to the Atlantic near Cape Higues. On its left bank is the town of Fuenterabia, where the army of Charlemagne was defeated by the Gascons. On Oct. 7. 1813, Wellington, in his victorious career, crossed the Bidasoa at Irun, and the whole British army was encamped in France by the 10th of November.

BIDDING PRAYER. It was one part of the office of the deacons in the primitive Christian church to act as monitors and directors of the people in the exercise of their public devotions in the church; to which end they made use of certain known forms of words, to give notice when each part of the service began. This was called by the Greeks κηρύσσειν, and by the Latins *prædicare*, which therefore does not ordinarily signify to "preach," as some mistake it, but to perform the office of crier (κήρυξ, or *præco*) in the assembly; and hence Synesius and others call the deacons ἱεροκηρύκες, the "holy criers" of the church, appointed to bid or exhort the congregation to pray and join in the several parts of the service of the church. Analogous to this practice is the form "Let us pray," repeated before several of the prayers in the English liturgy, and used as a sort of proem in the simpler invocations of the Presbyterian church.

BIDDLE, JOHN, one of the most eminent English writers among the Socinians, was born in 1615, at Wotton-under-Edge, in Gloucestershire, and educated in the free school of that place. Before he had completed his twentieth year, he published a translation of Virgil's Bucolics, and the first two satires of Juvenal. In 1634 he was entered at Magdalen Hall, Oxford, where he took his degree of M.A. In 1641 the magistrates of Gloucester elected him master of the free school of that city; in which office he acquitted himself to their entire satisfaction. But having expressed some peculiar opinions concerning the Trinity, he suffered various persecutions and imprisonments in the time of the Commonwealth. During one of these confinements, which lasted for several years, being reduced to great indigence, he was employed by Roger Daniel of London to correct the impression of the Septuagint Bible, which that printer was about to publish, and wished to render as accurate as possible. The general act of oblivion passed in 1651 restored him to liberty; but he was afterwards imprisoned on account of his tenets; and, at last, in October 1655, the protector banished him for life to the castle at St Mary's, one of the Scilly isles. In 1658 he was again set at liberty. But after the restoration of Charles II. he was fined in L.100, each of his hearers being amerced in L.20, and he was condemned to lie in prison till the fine was paid. Here the severity of his confinement brought on a disease, of which he died on the 22d of September 1662, in the forty-seventh year of his age. The Life of Biddle was published in Latin in 1682, by Mr Farrington of the Inner Temple, who represents him as possessed of extraordinary piety, charity, and humility. He had so happy a memory, that he retained word for word the

Bid-doomahs || Bidloo.

whole New Testament, not only in English, but in Greek, as far as the fourth chapter of the Revelation of St John. (See also Toulmin's *Life of Biddle*.)

BIDDOOMAHS, a fierce and piratical tribe who inhabit a cluster of large rugged islands in the eastern part of the great African lake called the Tsad. They neither sow, plant, nor rear cattle, but maintain themselves by plunder. They own nearly a thousand barks, with which they have made themselves complete masters of this water, and extend their ravages round the whole circuit of its shores. Some of these men, whom Major Denham saw at Bornou, appeared to him the wildest and rudest human beings he had ever beheld. This tribe was lately visited by Dr Overweg, as mentioned in the article AFRICA. He was well received by them; but describes them as being constantly at war with their neighbours of Bornou and Wadai, and as using boats more than 40 feet in length, without sails, but propelled by long poles.

BIDEFORD, a borough, market-town, and seaport, in the county of Devon, 29 miles N.W. of Exeter. It is pleasantly situated on the slopes of two hills which rise on either side of the river Torridge, near its confluence with the Taw, and about four miles from the sea. The two portions of the town are connected by a bridge of fourteen arches, said to have been built early in the fourteenth century. This bridge is endowed for its repair with lands which produce an annual rent of from L.300 to L.400. It forms a favourite promenade. Many of the houses are constructed after the ancient fashion, with bricks and wooden framework, and the streets are well paved and lighted. It contains an ancient church with a tower and six bells, several dissenting places of worship, a free grammar-school, and several other schools, a literary and scientific institution, a reading-room, a town-hall, a hospital for aged poor, and a dispensary.

Bideford was once a place of some commercial importance, and has still considerable shipping trade. It imports timber from Canada and the Baltic, with fruits, wines, and brandies from the south of Europe; and exports oak-bark, sails and cordage, earthenware, and corn, to Ireland, Wales, Scotland, the Channel Islands, &c. Vessels of 500 tons come up at high tide to the quay. Manufactures—earthenware, ropes, sails, and leather. There is also some ship-building. Corporation—a mayor, three aldermen, twelve councillors. Pop. (1851) 5775.

BIDENS, a botannical genus of the natural order of Compositæ. See BOTANY.

BIDENTAL, in *Roman Antiquity*, a place blasted with lightning, and where if a person were killed he was usually buried. The spot was immediately consecrated with the sacrifice of a *bidens*, *i. e.* a two-year old sheep, was surrounded with a ditch, wall, or other fence, and ever afterwards accounted sacred. The officiating priests were called *Bidentales*.

BIDET, a nag or little horse formerly allowed to each trooper and dragoon for carrying his baggage.

BIDIÆI (βιδιαῖοι, βίδεοι, βίδυοι), magistrates at Sparta who inspected the gymnastic exercises. They were either five or six in number, and, as Böckh has shown, were distinct from the *Nomophylaces*, who appear to have exercised a higher authority in the state.

BIDPAI, or PILPAY, the Hindu author of the celebrated fables called in India *Pancha Tantra*, or "the five sections," which has been translated into Tamul, French, Latin, Spanish, and part into English, by Sir Charles Williams and by Sir William Jones. A good account of this work is given in vol. i. of the *Royal Asiatic Society's Transactions*, by H. H. Wilson, from which it appears that scarcely any book but the Bible has been translated into so many languages.

BIDLOO, GOTTFRIED, a celebrated Dutch surgeon and anatomist, born at Amsterdam, March 12. 1649. In 1688 he was chosen professor of anatomy at the Hague, and in 1694 at Leyden, when he was appointed physician to William III. of England, who permitted him to retain his professorship. He published in Latin, 1. The Anatomy of the Human Body, demonstrated in 105 cuts, explained by the discoveries of the ancient and modern writers. (Cowper, the English anatomist, bought up 300 copies of the plates of this work, and published them at Oxford in 1698 as his own.) 2. An Oration upon the Antiquity of Anatomy; 3. A Letter to Anthony Leeuwenhoeck on the animalcules sometimes found in the liver of sheep and other animals; 4. Two Decades of Dissertations in Anatomy and Chirurgery; and other pieces. He died at Leyden in April 1713.

Bidschow || Bigamy.

BIDSCHOW, NEW, capital of a circle of the same name in the Austrian kingdom of Bohemia, is situated on the river Cydlina, 50 miles E.N.E. of Prague. It has some trade in cattle, with manufactures of linen and cotton goods and leather. Pop. 4000, of whom about 500 are Jews, who have a synagogue here.

BIEDENCOPF, a city of Hesse-Darmstadt, province of Upper Hessen, on the river Lahn. It is a town of much industry, containing 3580 inhabitants, employed in making cloth, baize, blankets, and various other kinds of goods.

BIELEFELD, a walled town in the Prussian province of Westphalia, government of Minden, and capital of a circle of the same name. It is pleasantly situated at the foot of a hill on the river Lutter, on the line of the Minden and Cologne railway, 26 miles S.W. of Minden. It was formerly the capital of the county of Ravensberg, and is now the centre of the Westphalian linen trade, with extensive bleaching-fields, &c. It has a gymnasium, several schools, and 10,308 inhabitants. The circle in 1849 contained one city, six market-towns, thirty-one villages, and 47,739 inhabitants.

BIELITZ, a town of Austrian Silesia, in the circle of Teschen, 16 miles N.E. of the town of that name, on the left bank of the Biala. It has considerable manufactures of fine cloths and cassimeres. The ducal palace and park adjoining are very magnificent. Pop. 6000.

BIELLA, an Italian province of the kingdom of Sardinia. It is a mountainous district, bounded on the N. by Sesia, on the E. and S.E. by Vercelli, on the S.W. and W. by Ivrea, and on the N.W. by Aosta. Area 264 square miles; pop. in 1848, 130,691. The capital, from which the province derives its name, is on the banks of the rivers Cervo and Aurena, 38 miles N.E. of Turin. Pop. between 8000 and 9000, employed chiefly in the manufacture of silk and linen goods, and in the cultivation of vines. Long. 7. 50. E. Lat. 45. 55. N.

BIER, a wooden carriage or frame for carrying the bodies of the dead to the place of interment.

BIFRONS, double-fronted, an epithet of the god Janus, who was represented with two faces.

BIGA, or BIGÆ, in *Antiquity*, a chariot with two horses abreast. Races of chariots with two horses were introduced into the Olympic games in the 93d Olympiad; but the invention was much more ancient, as we learn that the heroes of the *Iliad* fought in chariots of that kind. The moon, the night, and the morning, are by mythologists supposed to be carried in *bigæ*, but the sun in *quadrigæ*. Statues in *bigæ* were at first only allowed to the gods, but were afterwards conceded to conquerors in the Grecian games. See CHARIOT.

BIGAMY (compounded of the Latin *bis*, twice, and the Greek γαμέω, I marry) literally signifies being twice married; but with us the term is used as nearly synonymous with polygamy Wherever Christianity prevails, the union with more than one spouse is condemned by religion, public opinion, and law; although in the polemical contests of the Reformation there was some risk of the principle being relaxed, in the zeal with which the spirit of celibacy attri-

Bigamy.

buted to the Church of Rome was controverted. Most nations of modern Europe have taken their law of bigamy in some measure from the canon law; but England, with her usual jealousy of the influence of that system, has dealt with bigamy penally through the statute law. A second marriage while the former husband or wife is still living, is simply null by ecclesiastical law. By the Act of 9th Geo. IV. cap. 31. § 22, amending first of James I., cap. 10, the offence is declared felony, and all concerned in it as principals or accessories are liable to transportation for seven, or imprisonment with hard labour for two years. By the act of 1853 this, with other offences incurring transportation, may be punished with penal servitude. The statute law makes an exception of cases where the second marriage is a question of foreign law, or where it has been contracted in innocent unconsciousness; as for instance where the spouse of the first marriage has been for seven years absent, and is believed to be dead.

The offence is not incurred under the act where at the time of the second marriage the party is "divorced from the bond of the first," or where it has been declared "void by the sentence of any court of competent jurisdiction." But here the rigid character of the English law comes in conflict with those systems which, founded on the common principles of canonical jurisprudence, are easily adjusted to each other. The English courts, for instance, counting an English marriage as indissoluble by law, have refused to admit a Scottish divorce as having any effect on the condition of the married persons; and in the celebrated case of Lolley, who had been divorced for adultery in Scotland and married again in England, on the understanding that he was safe from penal consequences, sentence was passed on the verdict of a jury after solemn argument before the twelve judges. (*Russell and Ryan's*, cc. 237.) In the subsequent case of Conway *v.* Beazeley (1831, Haggart's *Ecclesiastical Cases*, iii. 639), the sweeping character of this decision seemed to create some uneasy doubts; but it was unnecessary in Beazeley's case to decide the ultimate question whether the bond of the English marriage can ever in any circumstances be legally dissolved, and it was held that a Scottish marriage following a Scottish divorce was ineffective against a previous English marriage, the parties having their domicile in England. The question how the law would have stood had they been domiciled in Scotland was left open.

In Scotland, at the date of the only statute respecting bigamy, that of 1551, cap. 19, the offence seems to have been chiefly considered in a religious point of view, as a sort of perjury, or violation of the solemn vow or oath which was then used in contracting marriage; and, accordingly, it was ordained to be punished with the proper pains of perjury. But this injunction has not in every instance been complied with; and, from considerations of policy or expediency, the court has long been in use to inflict an arbitrary punishment, suited, as nearly as may be, to the degree and measure of guilt brought home to the prisoner. The most important point concerning the description of bigamy which is the contracting of a second marriage during the subsistence of the first, relates to the quality of the two marriages, and involves the nice and delicate inquiry whether both must be marriages by formal celebration, or whether the charge will lie although both or one of them be contracted in that loose and unceremonious fashion which is sustained, in single cases, by the law and custom of Scotland. And here it may be observed, in the first place, that from the general strain and language of the statute above referred to, which passed at a time when there was no marriage without formal celebration, the presumption appears to be in favour of the more lenient opinion; and this is further confirmed by the circumstance that the application of the pains of perjury to this offence seems plainly to presuppose the contempt of a solemn oath or vow, and a gross abuse of the service of the church. The most favourable case for the offender, therefore, is that where both connections are of this loose and ambiguous character, as by promise and *copula*, courtship and acknowledgments, or the like: for here it may be urged that there has been no solemn entry into the holy state of matrimony, and no prostitution of religious ceremonies or ecclesiastical ministrations; and that circumstances which may be held relevant in a civil question of *status*, if consisting merely of probabilities and presumptions of law, cannot afford that full and decisive proof of *dole*, or of a settled purpose to marry and betray, without which there ought to be no conviction of the crime of bigamy. Secondly, although this argument does not fully apply to the case of one who, after having duly solemnized a marriage, betakes himself to some clandestine and irregular connection; yet it may still be argued, that, as he knew himself to be already married, and consequently for the time incapable of contracting a second marriage, so it ought to be presumed in his favour as long as it reasonably can, and until he take the decisive step of again undergoing the ceremony, that he had no abusive or deceitful purpose in view, but merely intended an intercourse of a different sort, highly immoral in itself, but by no means tantamount to the celebration of a second marriage. Thirdly, a more unfavourable case than either of the former is that of a regular marriage subsequently to some clandestine connection; yet even here it is doubtful whether we have got the proper materials of the crime of bigamy. For, in those anomalous situations where the female has not been in possession of the repute and status of a married woman, but is merely a claimant or pretender to that character, it may be exceedingly doubtful whether, after all, the man intended to marry, notwithstanding what the civil court may have found; and, while such a doubt exists, it may deserve consideration whether the party can be reasonably and consistently held to have committed the particular crime contemplated by the law. But this will scarcely apply to the case where, instead of a secret and ambiguous intercourse, the woman has been supposed and held to have been in the full and continued enjoyment, not only of that degree of repute which a civil court might possibly sustain as sufficient to entitle her to the legal character and privileges of a wife, but of that public and invariable character which prevents any doubt being raised as to the understood relation of the parties. So much for the form of the two marriages. The other qualities which must unite in the first marriage to bring it under the safeguard of the law are, 1. That it must be a lawful marriage, such as has not been contracted in contempt of any injunctions of law relative to proximity of kindred or previous conviction of adultery; and, 2. That it be not only a lawful, but a subsisting marriage, the parties living together lawfully married and undivorced. In every case the second marriage is null from being contracted during the subsistence of a previous one; and if it be also an incestuous, adulterous, or otherwise forbidden marriage, this additional aggravation cannot alter the character or shelter from the pains of the crime of bigamy. Further, it is obvious that, according to the circumstances of the case, the guilt of this offence may either be chargeable exclusively against one of the parties, in whose person there is a double marriage; or it may be the common guilt of both the parties to the second marriage, although to one of them it may be a first marriage. (Hume's *Commentaries*, vol. i. p. 459 *et seq.*)

Bigbone Lick || Biggar.

BIGBONE LICK, a district in Kentucky, so called from the number of bones of the *mastodon* and *elephas primigenus* there discovered in the gravel resting on the clay of a swampy soil.

BIGGAR, a town and parish of Scotland, in the county of Lanark. The town is small, but the main street, though

Biggleswade || Bijanagur.

irregular, is broad and spacious. The only building worthy of notice is the church, which was collegiate, and founded in 1545, by Malcolm Lord Fleming, who liberally endowed it. The parish contains vestiges of three Roman camps and a large tumulus. The remains of Biggar Castle are situated in a bog about a quarter of a mile south of the town. Biggar is distant from Edinburgh twenty-seven miles S.W. Pop. of town (1851) 1530.

BIGGLESWADE, a market-town in the county of Bedford, forty-five miles from London. It is agreeably situated on the river Ivel, by which the town and neighbourhood are supplied with abundance of coal, timber, and merchandise. The land near it is remarkably prolific; and being cultivated chiefly as gardens, it yields abundant crops of culinary vegetables, and a large supply of seeds for the London seedsmen. Market-day Wednesday. Pop. (1851) 3976.

BIGHORN RIVER, in North America, is said to rise in the Rocky mountains, near the Yellow Stone river and the sources of the Platte, and then to find its way through the eastern range of the Rocky mountains. Taking a northerly direction, it falls into the Yellow Stone river in about the 47th degree of north latitude. In its long course it receives two considerable rivers, one from the west and the other from the south; and being unobstructed by falls, it is navigable for canoes to a great distance, through a fine, rich, open country, well supplied with timber.

BIGHT (Dutch *bogt*, participle of *boogen*, to bend), a bend in the sea-coast, forming an open bay; also a round of a rope or cable when coiled.

BIGNON, JEROME, a French writer, was born at Paris in 1590. Under the care of his father he early acquired uncommon knowledge in philosophy, mathematics, history, civil law, and divinity; and had almost completed his studies at an age when it is usual to send children to school. At ten years of age he gave the public a specimen of his learning in a *Description of the Holy Land;* and two years after he published a *Discourse concerning the principal Antiquities and Curiosities of Rome*, and a *Summary Treatise concerning the Election of Popes*. Henry IV. desired to see him, and appointed him page to the dauphin, who was afterwards Louis XIII. At this time he wrote a treatise on the precedency of the kings of France, which he dedicated to Henry IV., by whom he was ordered to continue his researches on the subject; but the death of that prince interrupted his design. In 1613 he published the *Formulæ of Marculphus*. In 1620 he was made advocate-general in the grand council, and discharged that post with such reputation that the king nominated him some time afterwards counsellor of state, and at last advocate-general in the parliament. He resigned his offices in 1641, and the year following was appointed principal keeper of the king's library; but he was obliged to resume his office of advocate-general, which he continued to hold till his death in 1656.

BIGNONIA, a genus of magnificent shrubs. See BOTANY.

BIGOT, a person obstinately and perversely wedded to some opinion or practice, particularly of a religious nature. Camden has probably hit upon the true origin of the word. He relates, that when Rollo, Duke of Normandy received Gisla, the daughter of Charles the Simple, in marriage, together with the investiture of that dukedom, he would not submit to kiss Charles's foot; and when his friends urged him by all means to comply with that ceremony, he made answer in his peculiar dialect, "NE SE, BY GOTT;" upon which the king and his courtiers, deriding him, and corruptly repeating his answer, called him *bigot:* hence the Normans were called *bigods*, or *bigots*.

BIJANAGUR, an ancient city in the south of India, in the Balaghaut ceded territories, once the capital of a great Hindu empire, though now in ruins. It is situated on the south bank of the Toombuddra river, directly opposite to Annagoondy. The city has been inclosed with strong stone walls on the east side, and is bounded by the river on the west, the circumference of the whole appearing to be about eight miles. The streets of this city, from thirty to forty yards wide, can be traced between the immense piles of rocks crowned with pagodas; and one street yet remains perfect. The building of this metropolis was begun in 1336. Between the sovereigns of the principality of which it was the capital, and the Mahommedan sovereigns of the Deccan, constant hostility was maintained; and in 1564, Ram Rajah, the sovereign of Bijanagur, was totally overthrown on the plains of Tellicotta, by a combination of four Mahommedan sovereigns of the Deccan, who immediately marched to the metropolis, which they abandoned to pillage; and since this period it has lain in ruins. Travelling distance from Calcutta, 1120 miles. Lat. 15. 19. Long. 76. 32.

Bilbao

BILBAO (*i. e.* "the beautiful bay"), a city of Spain, capital of the province of Viscaya (Biscay), is situated in a small and fertile plain bounded on three sides by mountains, on the banks of the river Nervion (or, as it is called in the Basque language, Ibaizabal), six miles from its mouth. This river, which divides the old town from the new, is crossed by an ancient stone bridge of two arches, and also by a modern suspension bridge. The houses in the principal streets are built of hewn stone, several stories in height, with projecting eaves, which throw a deep shadow. The streets have an air of cleanliness and quiet, no waggons or carts being permitted to enter the town. The transport of goods is carried on by means of trucks. The principal public buildings are the churches and monasteries, a spacious hospital with 600 beds, town-hall, custom-house, charity-house, theatre, a new college, and a fine *abattoir* of Tuscan architecture. Of the educational institutions, the principal are, the *Colegio General de Vizcaya;* the schools supported by the board of trade for affording gratuitous instruction in design, architecture, languages, and mathematics; a nautical academy; besides several other public schools, and twenty-four private academies. Pop. about 15,000, chiefly engaged in agriculture, trade, and the iron manufacture. It may be mentioned that the women of the humbler class are much employed in masculine occupations, such as carrying burdens, &c., for which they are well fitted by their robust and vigorous frames. The climate of Bilbao, though humid, is on the whole healthy, though pulmonary diseases are somewhat frequent. The *Arenal*, which is a favourite promenade, extending along the right bank of the Nervion, is ornamented with rows of fine trees, and diversified with houses, gardens, warehouses, &c. The other favourite walks are the *Campo Volantin*, to the north of the Arenal; and the *Paseo de los Caños*, so called from its forming the roof of the great aqueduct for conveying the water of the river to the town.

Bilbao is the principal seat of foreign commerce in the north of Spain. The tide ascends as high as the town, but the river is only navigable for small vessels above the port of Portugalete, at its mouth. The average value of the exports, consisting chiefly of wool, iron, hardwares, fire-arms, wheat, wine, oil, fruit, chestnuts, madder, &c., is estimated by Madoz at about L.500,000, of which sum about one-fourth is of native and colonial produce. The average value of the imports—including cotton and woollen stuffs, hemp, sheet-iron, steel, coffee, sugar, &c.—is, according to the same authority, about L.156,000, of which about the half is foreign. Principal manufactures, hardware, woollens, paper, hats, leather, copper goods, &c. The iron-mines in the vicinity are very productive; and Bilbao sword-blades have long been celebrated. Lat. 43. 15. N. Long. 2. 56. W.

Bilbao was founded A.D. 1300, by Don Diego Lopez de Haro. At the end of the fifteenth century it was considered of sufficient importance to supersede Burgos as the seat of the *Consulado*, or supreme tribunal of commerce. During the Peninsular war Bilbao was sacked by the French, and

in the recent Carlist wars it twice sustained severe sieges. See SPAIN. (Madoz, *Dicionario de España;* Ford, *Handbook of Spain.*)

BILBOES, a punishment at sea, answering to that of the stocks on land.

BILDERDYK, WILLEM, a Dutch poet and historian, born at Amsterdam in 1756. His best known productions are his poem on *The Love of Fatherland*, his translation of the *Œdipus Tyrannus* of Sophocles, his *Buiten Lieven*, or *Rural Life*, and *The Destruction of the First World.* He was pensioned by Louis, King of Holland; but neglected by the succeeding government. His *History of Holland* was edited by M. Tydemann after his death, which occurred at Haarlem in 1831.

BILDULGERID. See BLED-EL-JEREED.

BILFINGER, GEORG BERNHARD, was born on the 23d of January 1693, at Canstadt in Wirtemburg. His father was a Lutheran minister. By a singularity of constitution, hereditary in his family, Bilfinger came into the world with twelve fingers and twelve toes. An amputation happily corrected this deformity. Bilfinger, from his earliest years, discovered the greatest inclination to learning. He studied in the schools of Blaubeuern and Bobenhausen, and afterwards entered into the theological seminary of Tübingen. The works of Wolf, which he studied in order to learn mathematics, soon inspired him with a taste for the Wolfian philosophy and that of Leibnitz; a passion which made him neglect for some time his other studies. Returning to theology, he wished at least to try to connect it with his favourite science of philosophy; and in this spirit he composed a tract entitled *De Deo, Anima, et Mundo.* This work, filled with new ideas, met with great success, and contributed to the advancement of the author, who was appointed soon after to the office of preacher at the castle of Tübingen, and of reader in the school of theology; but Tübingen was now become too small a theatre for him. He obtained from his friends in 1719 a supply of money, which enabled him to spend some time at Halle, in order to attend the lectures of Wolf; and, after two years of study, he returned to Tübingen, where the Wolfian philosophy was not yet in favour. He found his protectors there cooled, saw his lectures deserted, and perceived himself shunned, from the dislike of his new doctrines: his ecclesiastical views also suffered from the same cause. By the intervention of Wolf, he received an invitation to Petersburg, where Peter I. wished to appoint him professor of logic and metaphysics, and member of his new academy. He was received in that city, where he arrived in 1725, with the consideration due to his abilities. The Academy of Sciences of Paris having proposed about this time the famous problem on the cause of gravity, Bilfinger gained the prize, which was a thousand crowns. The reputation of this success was spread among the learned of Europe; and the Duke Charles Edward of Wirtemburg, finding that the author of this admired memoir was one of his subjects, hastened to recal him into his dominions. The court of Russia, after having made some useless attempts to detain him, granted him a pension of four hundred florins, and a present of two thousand, in reward of an invention relative to the art of fortification. He quitted Petersburg in 1731. Returned to Tübingen, Bilfinger soon excited considerable attention in that quarter, both by his own lectures, and by the changes which he introduced into the school of theology. After his return to Tübingen, the Duke Charles Alexander appointed him privy counsellor in 1735. This nomination was not a simple honorary title. Bilfinger saw himself raised at once to a power almost unlimited. He resisted some time a promotion for which he did not think himself qualified. In accepting office his first care was to acquire the knowledge necessary to the discharge of its duties. He employed almost two years in assiduous labour to instruct himself thoroughly in the statistics of the country, its political situation, its constitution, and its interests; and became, at the end of all this study, one of the most enlightened ministers that his country had yet produced. Bilfinger was placed in a situation too elevated not to excite jealousy and hatred. He felt it, and wished to quit the ministry; but the court refused to receive his resignation, soon after the tender of which the duke died. Bilfinger received from his successor all the consideration and all the friendship which he had experienced in the beginning of his career. Enjoying a confidence without bounds, he had the power to realize, without obstacle, those plans of administration with which the most enlightened patriotism had inspired him; and Wirtemburg still feels the happy influence of his ministry. Commerce, public instruction, and agriculture, flourished under his care. The culture of the vine, of so much importance in that country, was one of the principal objects of his attention. We ought not to forget that he was the original author of that strict union which has long united Wirtemburg and Prussia, and of the importance to which the hereditary prince of Wirtemburg was raised at the court of Berlin. He has been reproached with being irascible; but, in spite of some slight blemishes, the memory of Bilfinger will be always dear to his countrymen, and honoured by all Germans. Wirtemburg reckons him among the greatest men which she has produced, and proposes him as a model to her statesmen and her men of letters. He was never married, and left no issue. He died at Stuttgardt on the 18th of February 1750. His works, besides various papers separately published in the Memoirs of the St Petersburg and Paris Academies of Science, are numerous and valuable. (See *Biographie Universelle*, tom. iv.) (W. H–Z–T.)

BILGE of a ship, the bottom of her floor, or the breadth of the part she rests on when a-ground. *Bilge-water* is that which lodges on her floor below the level of the well of the pump; and *bilge-pumps*, or burr-pumps, are those that carry off the bilge-water. A ship is said to be *bilged* when her bilge is broken in and she springs a leak.

BILGE, the greatest circumference of a cask.

BILL, an instrument of iron, with an incurvated edge, and fitted with a handle. It is used by plumbers, basket-makers, and gardeners. Its form varies according to its particular use. When short it is called a *hand-bill*, and when long a *hedge-bill.*

BILL, in *Nautical Language*, the point of the fluke of an anchor.

BILL, in *English Law*, a declaration in writing, expressing either some wrong the complainant has suffered from the defendant, or a fault committed by the person complained of against some law or statute. In Scottish law, every summary application, by way of petition to the Court of Session, is called a *bill.*

BILL, in commerce, has been usually defined a writing in which one man is bound to another to pay a sum of money, on a day that is future, or presently on demand, according to the agreement of the parties at the time when it is drawn; and on which, in the event of failure, execution may be summarily done to enforce payment.

BILL of Exchange. See EXCHANGE; and BOOK-KEEPING.

BILL of Lading, a document by which the master of a ship acknowledges to have received on board in good order and condition certain specified goods laden by some particular shipper, and binds himself to deliver them in like good order and condition (the dangers and accidents of the seas, fire, enemies, &c., excepted) to the assignees of the shipper at the port of destination, on payment of a stipulated freight. Bills of lading are usually drawn out in sets of two, three, or four copies, "one of which bills being accomplished the others stand void." Each of these copies must be written on a sixpenny stamp.

A bill of lading is a negotiable document, and may, like a bill of exchange, be transferred by indorsation, either blank,

Bill of Mortality || Billiards.

or in favour of any particular assignee. The shipmaster is bound to deliver the goods to the holder of the bill of lading, who on his part becomes responsible for the freight stipulated as payable on delivery. If the goods be lost or damaged by any causes not falling within the exception of the "dangers and accident of the seas, &c.," as for instance by improper stowage, the holder of the bill of lading may recover the damages from the master or owners of the ship.

Bills of lading should never be granted till the goods are actually on board, otherwise the shipmaster will be personally liable for their value, failing delivery, to any individual who may have acquired the bill of lading for an onerous consideration. In a recent case of this nature it was decided that the *owners* of the ship could not be held liable for the value of the goods, on the ground that the shipmaster, in granting bills of lading for goods not on board, was acting beyond the scope of his authority as their agent. (J. W—K.)

Bill of Mortality, a periodical register of the numbers of births and burials within a certain district. See MORTALITY, HUMAN.

Bill in Parliament, a draft of a proposed act or statute, public or private, containing the substance of a measure submitted to parliament, and subject before passing to modifications in the way and manner to be afterwards described, or to rejection. For the parliamentary procedure in bringing in bills, discussing them, and passing them into laws, see PARLIAMENT; STATUTES; LEGISLATION.

BILLERICAY, a market-town, parish of Burstead, hundred of Barstable, and county of Essex, 24 miles from London. It is situated on an elevated plain, commanding a fine view of the rich vale of the Thames. Pop. (1851) 1533.

BILLET, in *Heraldry*, a bearing of an oblong form.

BILLETING, the quartering or lodging of soldiers in private houses, by billets or tickets.

BILLETON, an island of the East Indies, belonging to the Dutch, situate between Sumatra and Borneo, in Lat. 3. S. Long. 108. E. It is of a circular form, about 50 miles in length by 45 in breadth; and is rich in wood, iron ore, and tin. It has a population of about 6000, and is much infested by pirates.

BILLIARDS, a well-known game, played on a rectangular table with ivory balls, which are driven into hazards or holes, according to certain rules. This game was invented by the French, and was originally played in a manner different from that which is at present practised, by having a pass or iron fixed on the table, through which the balls at particular periods of the game used to be played; but this method is now quite disused.

The table on which the game is played is generally about twelve feet long and six feet wide, in the exact form of an oblong: it is covered with fine green cloth, and surrounded with cushions to prevent the balls running off, and to cause them to rebound. There are six holes, nets, or pockets, fixed at the four corners, and in the middle, opposite to each other, to receive the balls, which when driven into them are called hazards. The making of a hazard, that is, putting the adversary's ball in, at the usual game reckons for two in favour of the player. The game is played either with maces or with cues. The first is a long straight stick, with a head at the end; the second is a thick stick, diminishing gradually to a point of about half an inch diameter or less; and this instrument is played over the left hand, and supported by the fore-finger and thumb.

The rules generally observed at the common game are these:—1. For the lead, the balls must be put at one end, and the players must strike them against the farthermost cushion, in order to see which will be nearest the cushion that is next to them. 2. The nearest to the cushion is to lead and choose the ball if he pleases. 3. The leader is to place his ball at the nail, and not to pass the middle pocket; and if he holes himself in leading he loses the lead. 4. He who follows the leader must stand within the corner of the table, and not place his ball beyond the nail. 5. He who plays upon the running ball loses one. 6. He who touches the ball twice and moves it loses one. But these two rules are seldom or never enforced, especially in England. 7. He who does not hit his adversary's ball loses one. 8. He who touches both balls at the same time makes a foul stroke, in which case, if he should hole his adversary, nothing is gained by the stroke; but if he put himself in he loses two. 9. He who holes both balls loses two. 10. He who strikes upon his adversary's ball and holes himself loses two. 11. He who plays at the ball without striking it, and holes himself, loses three. 12. He who strikes both balls over the table loses two. 13. He who strikes his ball over the table, and does not hit his adversary's ball, loses three. 14. He who retains the end of his adversary's stick when playing, or endeavours to baulk his stroke, loses one. 15. He who plays another's ball or stroke, without leave, loses one. 16. He who takes up his own ball, or his adversary's, without leave, loses one. 17. He who stops either ball, when running, loses one; and if it be near the hole, loses two. 18. He who blows upon the ball when running, loses one; and if near the hole, loses two. 19. He who shakes the table when the ball is running loses one. 20. He who strikes the table with the stick, or plays before his turn, loses one. 21. He who strikes his stick upon the table, and hits the ball, loses one. 22. If the ball stand upon the edge of the hole, and, after being challenged, fall in, it is nothing, but must be put up where it was before. 23. If any person, not being one of the players, stop a ball, the ball must stand in the place where it was stopped. 24. He who plays without a foot upon the floor, and holes his adversary's ball, gets nothing for it, but loses the lead. 25. He who leaves the game before it is ended loses it. 26. Any person may change his stick in play. 27. If any difference arise between players, he who marks the game, or the majority of the company, must decide it. 28. Those who do not play must stand from the table, and make room for the players. 29. If any person lay any wager, and does not play, he shall not give advice to the players upon the game.

Billiards.

Besides the common winning-game, which is twelve up, there are several other kinds of games, viz., the losing-game, the winning and losing, choice of balls, bricole, carambole, Russian carambole, the bar-hole, the one-hole, the four-game, and hazards.

The *losing-game* is the common game nearly reversed; that is to say, except hitting the balls, which is absolutely necessary, the player gains by losing. By putting himself in he wins two; by putting his adversary in he loses two; but if he pockets both balls he gets four. The *winning and losing game* is a combination of both games; that is to say, all balls that are put in by striking first the adversary's ball reckon towards game; and holing both balls reckons four. *Choice of the balls* is choosing each time which ball the player pleases. *Bricole* is being obliged to hit the cushion, and cause the ball to rebound, or return to hit the adversary's ball, otherwise the player loses a point. *Carambole* is a game introduced from France. It is played with three balls, one red, which is neutral, and is placed on a spot in a line with the stringing nail, or that part of the table from which the player strikes his ball at setting off, and which is marked on the edge of the table with two brass nails. Each antagonist, at the first stroke of a hazard, plays from a mark which is upon a line with it at the other end of the table. The chief object at this game is, for the player to hit with his own ball the two other balls, which is called a carambole, and by which the player wins two. If he puts in the red ball he gets three; and when he holes his adversary's ball he gets two; so that seven may be made at one stroke, by caramboling and putting in both balls. *Russian carambole* is played in the following manner: The red ball is placed as

Billon ‖ Bilson.

usual on the spot for that purpose; but the player, when he begins, or after having been holed, never places his ball on any particular place or spot, being at liberty to put it where he pleases. When he begins to play, instead of striking at the red ball, he leads his own gently behind it, and his antagonist is to play at which he thinks proper. If he plays at the red ball and holes it, he scores three as usual towards the game, which is twenty-four instead of sixteen points; and the red ball is put upon the spot again, at which he may strike a second time, or take his choice which of the two balls to push at, always following his stroke till both balls are off the table. He is entitled to two points each time that he caramboles, the same as at the other game; but if he caramboles, and puts his own ball into any hole, he loses as many as he might have got had he not holed himself. In other respects it is played like the common carambole game. The *bar-hole* is so called from the hole being barred which the ball should be played for, and the player striking for another hole. The player at the *one-hole*, though it seems to those who are not judges of the game to be a great disadvantage, has in fact the best of it; for as all balls that go into the one hole reckon, the player endeavours to lay his ball constantly before the hole, and his antagonist frequently finds it very difficult to keep one or other ball out, particularly on the leads, when the one-hole player lays his ball on the brink of the hole. The *four-game* consists of two partners on each side, at the common winning game, who play by succession after each hazard, or two points lost. *Hazards* are so called because they depend entirely upon the making of hazards, there being no account kept of any game. The only general rule here is not to lay any ball at hazard for the next player.

BILLON, in *Numismatics*, a composition of precious and base metal, in which the latter predominates.

BILMA, a town situated in the heart of the African desert, and the capital of the wandering tribe called the Tibboos. The place is mean and poor, surrounded with a mud wall. In its vicinity are a number of lakes, the waters of which, on evaporation by the heat of the sun, yield a quantity of very pure and fine salt. The largest of these lakes is at Agram, situated about four miles to the westward. This salt is the object of a very extensive and important trade, which consists in conveying the commodity to the countries in Central Africa. The Tibboos, however, an unwarlike race, are unable to secure to themselves the enjoyment of these natural treasures, but have the chagrin of seeing the Tuaricks, their neighbours, come and load their camels with this valuable article, which they then convey to the countries in the south. Near Bilma is a small circular spot, in which several springs bubble up, and maintain a brilliant verdure; but immediately to the south begins the most dreary part of the African desert, over which the caravans travel for fifteen days without discovering the slightest trace of vegetable life.

BILSAH, a town of Hindustan, in the territory of Gwalior or the possessions of Scindia, situated on the Betwah river. It is inclosed with a stone wall, defended by square towers and a ditch. The suburbs without the walls are not very extensive; but the streets are spacious, and contain some good houses. The town and the surrounding country are celebrated all over India for the excellent quality of the tobacco, which is bought up with great eagerness and exported. Pop. about 3000. Distance south from Gwalior 190 miles. Lat. 23. 30. Long. 77. 50.

BILSON, Thomas, bishop of Winchester, was born in that city in 1536. He was successively fellow of New College, Oxford, master of Winchester School, prebendary of the cathedral, and warden of Winchester College. In 1596 he was consecrated bishop of Worcester; and next year translated to the see of Winchester, and sworn of Queen Elizabeth's privy council. He was one of the principal managers of the Hampton Court conference in 1604; and he was the colleague of Dr Miles Smith, bishop of Gloucester, in the revision of the new edition of the Bible. He died in 1616, and was buried in Westminster Abbey. Bishop Bilson bore the character of a learned divine, an able civilian, and an upright man.

Bilston ‖ Binary Arithmetic.

His principal works are entitled, *The true difference between Christian Subjection and Unchristian Rebellion*, Oxf. 1585, 4to, Lond. 1586, 8vo; *The Perpetual Government of Christ's Church*, Lond. 1593, 4to, black letter; *The effect of certain Sermons touching the full redemption of mankind by the death and blood of Christ, &c.*, Lond. 1599, 4to; *The survey of Christ's suffering for man's redemption, and of his descent to Hades or Hell*, Lond. 1604, fol.

BILSTON, a market-town of England, in the parish of Wolverhampton, hundred of Leisdon, and county of Stafford; $2\frac{1}{2}$ miles S.E. of Wolverhampton. Bilston is chiefly indebted for its importance to the iron trade, for which it possesses many advantages. In the vicinity are very productive mines of coal and ironstone, as well as sand of the finest quality for casting. Its productions also find a ready exit by means of canals to London, Liverpool, Bristol, &c.; and the Willenhall station of the London and Birmingham railway is within $1\frac{1}{2}$ miles of the town. It has numerous furnaces, forges, rolling and slitting mills, for the preparation of iron. The town itself is very irregularly built; but has some handsome buildings, as St Leonard's and St Mary's chapels, and the Roman Catholic chapel. Bilston suffered severely from the cholera in 1832 and 1849. Pop. (1851) 23,527.

BIN (Saxon *binn* or *binne*), a chest for holding bread, corn, or other provisions. The open subdivisions for bottles in a wine-cellar are also called bins.

BINACLE, or Binnacle (formerly *Bittacle*, from the French *habitacle*), a wooden case or box in which the compasses are kept on board a ship, with lights to show the compass at night.

BINARY ARITHMETIC, that kind of notation in which unity or 1 and 0 only are used. This was the invention of Leibnitz, who shows it to be very expeditious in discovering the properties of numbers and in constructing tables; and M. Dangecourt, in the History of the Royal Academy of Sciences, gives a specimen of it concerning arithmetical progressionals, where he shows, that because in binary arithmetic only two characters are used, therefore the laws of progression may be more easily discovered by it than by common arithmetic. All the characters used in binary arithmetic are 0 and 1; and the cipher multiplies every thing by two, as in the common arithmetic by 10. Thus 1 is one; 10, two; 11, three; 100, four; 101, five; 110, six; 111, seven; 1000, eight; 1001, nine; 1010, ten; which is founded on the same principles with common arithmetic. Hence appears the reason of the celebrated property of the duplicate geometrical proportion in whole numbers, namely, that one number of each degree being taken, we may thence compose all the other whole numbers above the double of the highest degree. For example, 111 being the sum of 4, 2, and 1, or, analytically, of $100 = 4$, $10 = 2$, and $1 = 1$, or 7 in all, this property may serve assayers to weigh all kinds of masses with a little weight; and may be used in coins, to give several values with small pieces. The binary method of expressing numbers once established, all the operations will be easy; in multiplication, particularly, there will be no need for a table, or getting anything by heart. But the inventor does not recommend it for common use, because of the great number of figures required to express a number; adding, that if the common progression were from 12 to 12, or from 16 to 16, it would be still more expeditious; and that its use consists chiefly in discovering the properties of numbers, in constructing tables, and the like. What makes the binary arithmetic the more remark-

Binary Measure || Biography.

able is, that it appears to have been the same with that used four thousand years ago among the Chinese, and left as an enigma by Fohi, the founder of their empire as well as of their sciences.

Binary Measure, in *Music*, is a measure which is beaten equally, or where the time of rising is equal to that of falling. This is usually called *common time*.

Binary Number is that which is composed of two units.

BINGEN, a town in the grand duchy of Hesse-Darmstadt, province of Rhenish Hesse, and fifteen miles west of Mentz. It is pleasantly situated on the left bank of the Rhine, where that river receives the Nahe. It has a considerable trade in wine, grain, and cattle, and manufactures leather and tobacco. Pop. 4500.

BINGHAM, Joseph, a learned scholar and divine, born at Wakefield in Yorkshire, in September 1668; educated at University College, Oxford; and afterwards, by John Radcliffe, M.D., presented to the rectory of Headbournworthy, near Winchester. In this country retirement he began his laborious and valuable work entitled *Origines Ecclesiasticæ*, or Antiquities of the Christian Church, the first volume of which appeared in 1708. It was completed by the publication of the tenth volume in 1722. Notwithstanding his learning and merit, Bingham received no higher preferment than that of Headbournworthy till the year 1712, when he was collated to the rectory of Havant, near Portsmouth, by Sir Jonathan Trelawney, bishop of Winchester. He died August 17. 1723, in his fifty-fifth year.

Bingham, a market-town in the hundred of that name, in the county of Nottingham, 123 miles from London, and 8½ from Nottingham. It is situated in the fertile vale of Belvoir, and consists of two parallel well-paved streets, with a fine Gothic church, and a good market-place, in which a market is held on Thursday. Pop. of parish in 1851, 2054.

BINGLEY, a market-town in the west riding of Yorkshire, on the river Aire, 31 miles W.S.W. of York. The inhabitants in 1851 amounted to 5019, principally engaged in manufactures of worsted, cotton, and paper, which have been much improved during the last ten years. The town is well built and flourishing, and has a neat church, grammar-school, and several charities.

BINK, Jacob, a German engraver, who also designed well; born about 1500. Bartsch describes 98 prints by him. He seems to have died about 1550.

BINOMIAL, in *Algebra*, a root consisting of two factors connected by the sign *plus* or *minus*. Thus $a + b$ and $8-3$ are binomials, consisting of the sums and differences of these quantities. See Algebra.

BINTANG, one of the Dutch East India islands, S.E. of Singapore, in Lat. 1. 5. N. Long. 104. 30. E. It is about 24 miles in length by 12 in breadth, and is surrounded by numerous rocky islets, which render the navigation dangerous. Its principal exports are pepper, rice, and particularly *gambier*, from its chief town Rhio on the S.W. coast. Pop. 15,000.

BIOGRAPHY (*βίος*, life, and *γραφή*, a writing), the history of a life. Of this species of literary composition examples are preserved in the earliest records of antiquity. In Sacred Scripture we have the history of the lives of Abraham, Joseph, David, &c. In the first rank in Grecian literature stand the *Parallel Lives* of Plutarch, which comprise the biographies of forty-six of the most celebrated Greeks and Romans who flourished prior to his own time. The *Lives of the Philosophers* by Diogenes Laertius, the *Lives of Philosophers and Sophists* by Eunapius, and the *Lives of the Sophists* by Philostratus, are the other principal works of this class in the Greek language. Among Roman writers of biography the principal are Cornelius Nepos and Suetonius. Besides these there are other writers whose works, though in a certain degree biographical, more strictly belong to the province of history; as, for example, Sallust's account of the conspiracy of Catiline, the *Commentaries* of Julius Cæsar, and Quintus Curtius's account of the expedition of Alexander. Biography.

In all civilized countries biography has always formed a favourite subject of study. France has been especially prolific in biographical publications, and our own country can show a goodly array of volumes in this department of literature; and, indeed, the same may be said of Italy, Germany, and Spain. To enumerate even the principal works of this class, whether single lives or biographical collections and dictionaries, in any of these languages, would far exceed our limits. We shall therefore content ourselves with a few general reflections on the uses and peculiarities of biographical composition.

It is pleasant no less than instructive to be, as it were, introduced to the companionship of men who have been distinguished in the sphere which they occupied. If they be great and good men, we love to be made acquainted with the motives of their actions, to follow them in their wanderings, to mark the difficulties and the opposition they had to encounter in their honourable struggles through life, the energy and skill by which these were overcome, and the courage that animated them to persevere in their career of usefulness and honour.

If the author honestly exhibit the failings as well as the excellences of his subject, the reader will be warned of the quicksands and dangers that beset the path of life; and should he succeed in portraying aright the attractive lineaments of a virtuous character, he will insensibly arouse in the mind of the reader aspirations after the excellences which he is led to admire. The mind has a tendency to assimilate to the character of those with whom we associate; and to peruse the memoirs of wise and good men is living for the time in their company.

Every man, whatever be his sphere in life, has an influence for good or for evil on the society around him; and he who gives to the world the history of an exemplary life, reproduces in a certain degree the influence which had been extinguished by the hand of death. The biographer not only revives the lost influence, but by the circulation of his narrative he becomes the medium of more extended usefulness, and in some degree a benefactor of mankind.

Where personal character and habits form the principal subject of interest, a stranger stands at too great a distance to give to his portrait a faithful outline or correct colouring: a true picture can only be drawn by one whose friendly intercourse gave opportunity of marking the peculiar characteristics of his subject.

Autobiography, or memoirs of one's self, is preferable to biography only when the writer has something to communicate, by way of confession or explanation, of which no other person is cognisant. But it is almost impossible, nor is it perhaps desirable, that an autobiographer should disclose with unflinching impartiality the whole particulars of his life, and unveil the real motives of his actions.

"Thus conscience does make cowards of us all."

Nevertheless, in autobiography concealment itself is a species of disclosure. The moment a man begins to speak of himself, however cautious his mode of expression, the discerning reader will have little difficulty in appreciating his real character and the quality of his actions. What reader is blind to the bad temper, meanness, and impracticableness of Rousseau, notwithstanding his cunning attempts to disguise them? The autobiographer always betrays himself when he least suspects it: he exhibits his greatest weakness when he flatters himself that he is putting forth his strength. The task of the autobiographer is not only delicate but difficult. How frequently does the consciousness of sitting for one's portrait to another alter at once the

whole demeanour; but still more marked is the change when a man becomes the limner of his own mental likeness. In short, the obstacles to a successful execution of this experiment are almost insuperable.

Of autobiographies which interest principally as histories of the mind, the examples are rare; but those which are intended to amuse or instruct, as delineations of the times in which the writer lived, are innumerable. Of biography of all kinds the same may be said. The unparalleled increase of this department of literature in our own time may be regarded as one of the most characteristic features of the age; and, as must therefore be the case, the number of obscure or unimportant lives thus chronicled forms an enormous proportion to the histories that are truly deserving of record.

BIOLOGY (*βίος* and *λόγος*), a term introduced by Treviranus of Bremen, in place of physiology, to signify *the science of life.*

BION *of Smyrna*, a bucolic poet, who flourished about the year B.C. 280. He was an admirable poet, according to the accounts of his disciple Moschus; and the few pieces of his which are extant tend to confirm that opinion. The latter years of his life were spent in Sicily, where he died by poison. The best editions of the poems of Bion, including those of Moschus, are by Fr. Jacobs, Gotha, 1795; Gilbert Wakefield, London, 1795; and that of J. F. Manso, Leipzig, 1807, which contains an elaborate dissertation on his life and poetry, and a German translation.

BION, surnamed *Borysthenites*, a Scythian philosopher, born at Borysthenes. He flourished about B.C. 250, and resided for some time at the court of Antigonus Gonatas, king of Macedonia. He was the son of a freedman, and while young was sold as a slave to a rhetorician, who adopted him as his heir (Diog. Laert. iv.) Athenæus (xiii. c. 293) states that his mother was a Lacedæmonian courtezan named Olympia. He studied at Athens, where he became first an academic and a disciple of Crates, and then a Cynic; and after embracing the tenets of Theodorus the atheist, he finally became a pupil of Theophrastus the peripatetic. Bion was possessed of much natural acuteness; but his habits of life were grossly profligate. The keenness of his satire is alluded to by Horace, *Epist.* ii. 2. 60.

BIPES, a genus of reptiles, in which the hind feet alone are visible. See REPTILES.

BIQUADRATE, or BIQUADRATIC, is the next power above the cube, or the square multiplied by itself.

BIQUADRATIC EQUATION, an equation raised to the fourth power, or where the unknown quantity of one of the terms has four dimensions. Thus $x^4 + ax^3 + bx^2 + cx + d = 0$ is a biquadratic equation. See ALGEBRA.

BIQUADRATIC Parabola, in *Geometry*, a curve line of the third order, having two infinite legs tending the same way.

BIQUADRATIC Power of any number is the fourth power, or squared square of that number. Thus 16 is the biquadratic power of 2; for $2 \times 2 = 4$ and $4 \times 4 = 16$.

BIQUADRATIC Root of any number is the square root of the square root of that number. Thus the biquadratic root of 81 is 3; for the square root of 81 is 9, and the square root of 9 is 3.

BIR, or BEER, a town of Asiatic Turkey, in the government of Orfa. It occupies an elevated situation on the left bank of the Euphrates, which is here about 130 yards broad, deep and rapid, and is crossed by a bridge of boats. The town consists of about 2000 houses, mostly in a decaying state, and is protected by a citadel, which stands on a precipitous eminence, and by a wall in a dilapidated condition. Bir is a considerable thoroughfare from Aleppo to Orfa, Diarbekr, and Persia, and a considerable trade was formerly carried on to Baghdad by vessels descending the river. It is 144 miles N.E. of Aleppo, and 115 S.W. of Diarbekr. Long. 38. 6. E. Lat. 36. 48. N.

BIRBHOOM, a British district of Hindustan, in the province of Bengal, situated between Lat. 23. 32. and 24. 40. Long. 86. 25. and 88. 30., and containing an area of 4730 square miles, with a population of 1,040,876. Along the courses of the rivers Damooda and Hadjee, which traverse the southern and western parts of the district, coal and iron ore are found in large quantities. The district was acquired by the East India Company in 1765, by virtue of the grant of the emperor of Delhi. (E. T.)

BIRCH, THOMAS, D.D., a laborious and voluminous historical and biographical writer, born in London in 1705. His parents were Quakers; and his father was by trade a coffee-mill maker. By his unremitting diligence in his studies, though he had not the advantage of a university education, he soon became qualified to take holy orders in the Church of England. In 1728 he married the daughter of the Rev. Mr Cox, to whom he was curate; but in less than a year this lady died in childbed. In 1732 he was recommended to the friendship and favour of the Lord Chancellor Hardwicke, then attorney-general, to whom, and to the succeeding Earl of Hardwicke, he was indebted for all his preferments. In 1732 he obtained the living of Ulting in Essex; and in 1734 was appointed one of the domestic chaplains to the unfortunate Earl of Kilmarnock, who was beheaded in 1746. He became a member of the Royal Society in February 1734–35, and of the Society of Antiquaries in December 1735; and was afterwards director of the latter, which office he held till his death. Previously, the Marischal College of Aberdeen had conferred on him the degree of master of arts. In 1743, through the interest of Lord Hardwicke, he was presented by the crown to the sinecure rectory of Landewy Welfrey, in Pembrokeshire; and in 1743–44 he was preferred to the rectory of Sidington in St Peter's, in the diocese of Gloucester; but he appears to have quitted this charge almost immediately. On the 24th of February 1743–44, he was appointed to the united rectories of St Michael Woodstreet and St Mary Staining; and in 1745–46 to the united rectories of St Margaret Patens and St Gabriel, Fenchurch Street. In January 1752 he was elected one of the secretaries of the Royal Society. In 1753 the Marischal College of Aberdeen created him doctor of divinity; and in that year the same degree was conferred on him by Archbishop Herring. He was one of the trustees of the British Museum, for which honour he was probably indebted to the Earl of Hardwicke, as he also was for his last preferment, the rectory of Depden in Essex, to which he was inducted in February 1761. In the latter part of his life he was chaplain to the Princess Amelia. In 1765 he resigned his office of secretary to the Royal Society. His death was caused by a fall from his horse, or perhaps by a fit of apoplexy, on the road between London and Hampstead, in the sixty-first year of his age. Dr Birch bequeathed his library of books and manuscripts, and all his pictures and prints not otherwise disposed of by his will, to the British Museum. He likewise left about L.500, to be laid out in government securities, for the purpose of applying the interest to increase the salaries of the three assistant librarians.

His principal publications were, 1. The General Dictionary, Historical and Critical, including a new translation of Bayle, and interspersed with several thousand new lives, in ten volumes folio. 2. Dr Cudworth's Intellectual System, improved from the Latin edition of Mosheim; his Discourse on the true Notion of the Lord's Supper; and two Sermons, with an account of his Life and Writings, 2 vols. 4to, 1743. 3. The Life of the Honourable Robert Boyle, 1744, prefixed to an edition of that philosopher's works. 4. The Lives of Illustrious Persons of Great Britain, annexed to the engravings of Houbraken and Vertue, 1747–1752. 5. An Inquiry into the share which King Charles I. had in the Transactions of the Earl of Glamorgan, 1747, 8vo. 6. An edition of Spenser's Faery Queen, 1751, 3 vols. 4to, with prints from designs by

Birch ‖ Bird's-Nests.

Kent. 7. The Miscellaneous Works of Sir Walter Raleigh, with his Life, 1751, 2 vols. 8vo. 8. The Theological, Moral, Dramatic, and Poetical Works of Mrs Catherine Cockburn, with a Life, 1751, 2 vols. 8vo. 9. The Life of Dr Tillotson, Archbishop of Canterbury, compiled chiefly from his original Papers and Letters; 1762, 8vo. 10. Milton's Prose Works, 1753, 2 vols. 4to, with a Life. 11. Memoirs of the Reign of Queen Elizabeth, from the year 1581 till her death; from the original papers of his intimate friend Anthony Bacon, Esq., and other MSS.; 1754, 2 vols. 4to. 12. The History of the Royal Society of London, from its first rise; 1756 and 1757, 4 vols. 4to. 13. The Life of Henry Prince of Wales, eldest son of James I., compiled chiefly from his own papers and other MSS., 1760, 8vo. His numerous communications to the Royal Society may be seen in the *Philosophical Transactions*.

BIRCH. See PLANTING and *Index*.

BIRD, WILLIAM, an eminent English composer, and one of the best organists of his time, was born about 1546, and died at London, 4th July 1623. He was organist of Lincoln cathedral in 1563; and in 1575 he and his master Tallis were gentlemen of the chapel royal, and organists to Queen Elizabeth. Bird was the earliest English composer of madrigals; and among his numerous sacred compositions, some are still much esteemed. His vocal canon *Non nobis Domine* is well known, and often sung. In his compositions there is a freedom and elegance rarely found in the music of that period. (G. F. G.)

BIRD. See ORNITHOLOGY.

BIRD'S-EYE VIEW, a perspective representation of objects as they appear when viewed from above.

BIRD-*Lime*, a viscid substance used for snaring birds. It is usually prepared by boiling holly bark ten or twelve hours; and when the green coat is separated from the other, it is covered up for a fortnight in a moist place; then pounded into a tough paste, and washed in a running stream till no motes appear. It is next put up to ferment for four or five days, and repeatedly skimmed. To prepare it for use, a third part of nut-oil, or thin grease, must be incorporated with it over the fire.

BIRDS, in *Heraldry*, according to their several kinds, represent either the contemplative or active life. They are the emblems of liberty, expedition, readiness, swiftness, and the like, and are therefore more honourable bearings than fishes. Birds must be borne in coat-armour, as is best fitting the propriety of their natural actions. Such as are either whole-footed, or have their feet divided, and yet have no talons, are said to be *membered;* but the cock, and all birds of prey with sharp and hooked beaks and talons for encounter or defence, are said to be *armed*. In the blazoning of birds, if their wings be not displayed, they are said to be borne close.

Bird's-Nests, Edible, the nests of a small Indian swallow, which are eaten as a delicacy. These birds abound on the sea-coasts of China and in Java at certain seasons of the year. They build in the rocks, and fashion their nests out of a gelatinous matter which they find on the shore. According to Kempfer, this substance is molluscæ or sea-worms; M. le Poivre supposes it to be fish-spawn; and according to Linnæus, it is a kind of medusa or jelly-fish. The nests are hemispherical, of the size of a goose's egg, and in substance much resemble ichthyocolla or isinglass. They are sent to all parts of the world, and are highly prized as a luxury. They abound in Sumatra, particularly about Croe, near the south end of the island. Four miles up the river of that name is a large cave, where the birds build in vast numbers. The nests are distinguished into white and black; but of these the former are more scarce and valuable, being found in the proportion of only one to twenty-five. According to Marsden's account, the white nests sell in China at the rate of 1000 to 1500 Spanish dollars the pecul; the black are disposed of at Batavia for about twenty dollars the same weight, and manufactured into glue. The difference of colour is said to be owing to the admixture of feathers. By steeping for a short time in hot water, the black nests are said to become in a great degree white. The natives enter the caves with torches, and by means of a ladder made of a single bamboo notched, they take the nests, which adhere in masses from the side and top of the rock. The more frequently and regularly the cave is stripped, the greater proportion of white nests is found; for which reason they destroy the old nests, in order that they may find their place supplied by white nests the next season. (See also Crawfurd's *Eastern Archipelago*, vol. iii. p. 432; and Count Hogendorp's *Coup d'Œil sur l'Ile de Java*, p. 291.)

Biren ‖ Birken-head.

BIREN. See ANNA IVANOVNA, and RUSSIA.

BIRGUS, a species of land crab, or crustaceous animal, that can live either on land or under water, having respiratory organs fitted for both modes of existence. The most remarkable is *B. latro*, that climbs cocoa trees to prey on the fruit, a native of Amboyna. This species is described by Cumming as inhabiting the islands in the Pacific, and we know that *B. laticauda* is found in Mauritius.

BIRKBECK, GEORGE, an English physician and philanthropist, born in Yorkshire in 1776. He early evinced a strong predilection for scientific pursuits; and shortly after graduating as doctor of medicine, he was appointed to the chair of natural philosophy at the Andersonian Institution of Glasgow. In 1804, with a view to the improvement of the working-classes of that town, he delivered for their behoof a gratuitous course of scientific lectures. From Glasgow he removed to London, where he endeavoured to prosecute his philanthropic schemes, at first without obtaining much encouragement, but ultimately with marked success. In 1827 he contributed to found the Mechanics' Institute. His coadjutors in this undertaking were Bentham, Wilkie, Cobbett, and other distinguished men. He was appointed director of the Institute, which he had originally endowed with the sum of L.3700. This office he held till his death, which took place on the 1st December 1841.

BIRKENHEAD, SIR JOHN, a political writer, born about 1615. He suffered imprisonment several times during the Commonwealth, for writing in favour of the exiled king. He was one of the earliest English journalists, having conducted a kind of weekly gazette, entitled *Mercurius Aulicus*, in one or more quarto leaves, from 1st January 1642 until the end of 1645. At the Restoration he received various preferments for his loyalty, and was elected member of parliament for Wilton. He died in 1679.

BIRKENHEAD, a seaport, market-town, and township in the union and lower division of the hundred of Wirrall, south division of Cheshire. It is situated on the river Mersey, opposite to and about $\frac{3}{4}$ of a mile west from Liverpool by ferry, 16 miles from Chester, and 202 from London. It comprises the ancient extra-parochial district or chapelry of Birkenhead, the former township of Claughton in Bidstone, and part of Oxton in Woodchurch. Birkenhead is of considerable antiquity. In 1150 a priory was founded in honour of St Mary and St James, by Harris de Massey, third baron of Durham-Massey, which had considerable endowments. The priors sat in the parliaments of the Earls of Chester, and enjoyed all the dignities and privileges of palatinate barons. The revenues of the priory were valued at the Reformation at L.90, 13s. according to Dugdale, but Speed makes it L.102, 16s. 10d. Of the priory building nothing now remains but a portion of the ivy-covered gable and Gothic window of the refectory. The priory-house—which was garrisoned by the royalists and captured by the parliamentary troops in 1644—was pulled down in 1843.

From an obscure fishing village, Birkenhead has become a large and important town with a rapidity truly marvellous. In 1818 the village consisted of the priory, the priory-house, three other houses, and a few cottages, and its population was not more than 50. In 1821 the population was 200,

Birkenhead.

in 1831 it was 2569, in 1841 it was 8227, and in 1851 it had risen to 24,175, with 3228 houses, and 503 buildings in course of erection. In 1823 the annual value of the assessable property was L.3101, and in 1847 it amounted to L.114,301.

The town of Birkenhead is built on a regular plan, the principal streets running nearly east and west (one of them, Conway Street, being upwards of two miles long), and crossed at right angles by shorter streets. The summit of the ground next the Mersey is occupied by Hamilton Square, which contains 6½ acres of ground. The houses are four stories high, with stone fronts, and the centres and ends of each side ornamented with Doric columns. The sides of the square coincide with the directions of the streets. Birkenhead in some respects may be considered a model town, its projectors at the outset providing for its future wants by sewering the streets at the time they were laid out. In 1833 an act was obtained for paving and improving the town, for regulating its police, and establishing a market. This was amended by another act in 1838; and in 1841 an act was obtained for lighting it with gas and supplying it with water. The level of the pumping-station is 104 feet above the sea, and the wells are sunk 294 feet deep in the red sandstone. A supply of excellent water is thus obtained, pumped to such a height that it will rise above the tops of the houses in Hamilton Square.

The market is in the form of a parallelogram, 430 feet long, and 131 feet wide, and is well supplied with all sorts of produce. It was opened July 12. 1845, at a total cost of nearly L.35,000. About 400 yards from the market, in Jackson Street, are situated the slaughter-houses, a massive structure of freestone, standing in a sufficient extent of ground to admit of extension to meet the exigencies of the town.

For about 1150 yards Conway Street is bounded on the south by Clifton park, a piece of ground of 180 acres beautifully laid out by Mr Panton with plantations, flowerbeds, lakes, and drives, for public recreation and enjoyment. The park was opened April 5. 1847. Near St James's Church, which forms a beautiful termination to Conway Street, it is proposed to form a public cemetery on the site of an old quarry on Bidston Hill.

Besides St James's Church, which is not completed, there are five other Episcopal churches, one in connection with the Established Church of Scotland, a Free Presbyterian church, a Roman Catholic, a Wesleyan, and an Independent chapel. Of Welsh churches and chapels, there are an Established church, an Independent, a Wesleyan Methodist, and a Calvinistic Methodist chapel. St Aidan's Theological College was established in 1846. Its patron is the Archbishop of Canterbury. The students are connected with the Liverpool Parochial Assistant Association, the object of which is to provide additional aid to meet the pastoral wants of Liverpool, Wallon, Birkenhead, and the neighbourhood. The Birkenhead Mechanics' Institution was established in 1840. There are numerous free schools in connection with the different churches and chapels. There is also a lying-in hospital, an infirmary, and a dispensary.

The late Mr William Laird, whose name is so well known in connection with iron ship-building, first conceived the idea of turning to advantage the capabilities of Wallasey pool for the formation of a dock. After a lapse of many years, the commissioners of Birkenhead, alive to the advantages which the project of Mr Laird would confer upon the town, employed Mr Rendel as their engineer, and applied to parliament for powers to construct works embracing a sea wall from Woodside to Seacombe, docks at Bridge-end, and a tidal basin of 37 acres, accessible at all times of the tide, by vessels of 12 feet draught; a basin of 16 acres for coasters, and a dam to pen up the waters of Wallasey pool into a float, like that at Bristol. The bill passed on the 15th July 1844, and the foundation-stone of the new docks was laid by Sir Philip de Malpas Grey Egerton, on Oct. 23. 1844. On the 5th of April 1847 the first dock was opened by Lord Morpeth, and called the Morpeth Dock. Subsequently the dock powers of the commissioners were transferred by act of parliament to a corporate body of trustees (thirteen); six of whom are elected by the bondholders, four by the commissioners of Birkenhead from their own body, and three by the commissioners of Wallasey from their own body. The docks are intended to bound the town on the north and north-east, and partly on the east, extending from the pier at Woodside-ferry to the Wallasey bridge. The Wallasey pool will form a great float of 150 acres. It separates Birkenhead from Bolton-cum-Seacombe in the parish of Wallasey, and will communicate on the east with a low-water basin of 37 acres, and on the S.E. with the Egerton dock of 3 acres. On the north the Egerton dock will be connected with the low-water basin, and on the S.E. with the Morpeth Dock. The Morpeth Dock communicates on the S.E. with a tidal basin of 16 acres for coasters. The total accommodation will be above 200 acres. The great sea-wall next the Mersey will be broken only by the entrance to the low-water basin of 27 acres. At its southern extremity is the basin of 16 acres, bounded on the south by the Woodside-ferry pier.

Birkenhead.

The company, established under an act of parliament, and called the Birkenhead Dock Warehouse Company, purchased a large extent of land fronting Wallasey pool, and laid it out to accommodate the rising traffic of the port. In April 1847 their first warehouses, capable of stowing 80,000 tons of goods, were opened. Each block of warehouses is detached and provided with water, and the whole premises are surrounded by a wall 12 feet high. A railway branching from the Chester and Birkenhead line is carried round the property. The company also built houses for their workmen, but although ingeniously constructed, the error of too great an economy of space has, despite very perfect internal arrangements, rendered this part of their speculation unremunerative.

The custom-house department of Birkenhead is under that of Liverpool, and the entries passed at the latter place answer for Birkenhead.

Many manufactories have sprung up on the margin of the pool, such as iron-foundries, gun-works, boiler-yards, potteries, varnish works, breweries, &c. No place could be better suited for the establishment of ship-building yards and manufactories, which require, on sanitary and economical grounds, to be situated at a distance from the inhabited portion of a large town.

In regard to traffic accommodation Birkenhead is well provided. It has three ferries with a hotel at each. The ferries of Woodside and Monks ferry belong by purchase to the commissioners of Birkenhead. The slips at Woodside are excellent, and the boats are admirably managed. The Monks ferry is in connection with the Chester and Birkenhead railway. The Birkenhead ferry and hotel are the property of the corporation of Liverpool.

The Chester and Birkenhead railway, 16 miles in length, connects Birkenhead with the midland counties, with the metropolis, and with Ireland. By a tunnel of about 500 yards long, the line is extended to the water's edge at Monks ferry. The station there is extensive, being 250 feet long, and 120 feet wide. Another extension line is carried from Grange Lane to the docks. It has two stations, one at Canning Street for passengers, and the other at the docks for goods.

The affairs of the township of Birkenhead are managed by 21 commissioners chosen by the rate-payers; seven of these retire annually, but are eligible for re-election. The commissioners of the town were constituted originally under an act passed June 10. 1833. The mayors and bailiffs of Liverpool, with the 4 junior aldermen, together with 60 other persons named in the act, were constituted the commissioners. A subsequent act of the 1st Vict. decreed, that

Birket-el-Keroun || Birmingham.

there were to be 24 commissioners, 3 of whom were to be appointed by the town-council of Liverpool, and the remainder elected by the rate-payers. In 1846 an act was passed for the exclusion of the Liverpool members. (J. N.)

BIRKET-EL-KEROUN, *i.e.*, the *Horn* or *Bow Lake*, the ancient Mœris, is in the province of Fayoum, in Central Egypt, in Lat. 29. 30. N. Long. 30. 31. E. This lake has undergone a remarkable diminution since the days of Herodotus. It was then from 400 to 500 miles in circumference, while its present length is about 30 miles, its greatest breadth about 6, and it is gradually contracting. Its waters are brackish, but it still abounds in fish. It communicates by two channels with the Nile. See EGYPT.

BIRKET-EL-MARIOUTH, or EL KREIT, known to the ancients as the Palus Marea or Mareotis, a lake in Lower Egypt, in Lat. 31. 4. N. Long. 30. 4. E., separated from the sea by the narrow peninsula on which Alexandria stands. After the fall of that city the waters of the lake were gradually dried up. In 1801 a French garrison took possession of Alexandria, and the British army sent to expel them cut a canal across the isthmus, and let in the waters of the sea. The old bed of the lake was covered to the extent of 30 miles in length, and 15 in breadth, while the depth of the water varies from 4 to 14 feet. See ALEXANDRIA, and EGYPT.

BIRMAH. See BURMAH.

BIRMINGHAM, or BERMINGHAM, a large commercial and manufacturing town, situated in a projecting angle of the north-western portion of the county of Warwick, near the confines of Staffordshire and Worcestershire. It is in 52. 59. N. Lat. and 1. 18. W. Long.: 102 miles in a straight line N.W. of London, and by the North-Western railway 112 miles. The parish of Birmingham is bounded on the E. and N.E. by the parish of Aston, and on the south by that of Edgbaston, both in the county of Warwick; and on the W. and N.W. by those of Harborne and Handsworth, in the county of Stafford. The parishes of Birmingham and Edgbaston, with about a third part of Aston, form the parliamentary and municipal borough; the total area in statute acres being 7831; of which Birmingham contains 2660, Edgbaston 2545, and Aston 2626.

The parish from which the town derives its name, is, with the exception of a small portion of land at its western and northern extremities, almost entirely covered with buildings. Edgbaston, from the circumstance of the fee-simple of almost the entire parish being vested in one proprietor, who exercises a stringent control as to the nature of the buildings erected, is the most pleasant and fashionable part of the borough.

Birmingham is situated nearly in the centre of England, built on the crest and sides of a gentle hill, and when viewed from the S.E. presents the appearance of a vast semicircle, the gradual elevation of the surface adding to the picturesqueness of the view. This circumstance, too, is favourable to its salubrity; and the general health of the inhabitants will bear comparison with that of any other large manufacturing district. Water is obtained in abundance at a medium depth of about 20 yards; and the town is further supplied by a company, whose distribution of this first necessary of life amounts to upwards of a million gallons per day, and occasionally even to upwards of two million gallons. One shallow river, the Rea, flows through the lower part of the town, and affords a convenient outlet for drainage.

The general appearance of the town, which in the earlier part of the present century was not of an inviting character, is rapidly improving. In addition to the public buildings, now becoming numerous, many judicious alterations have been effected by the widening of streets, the removal of unsightly buildings, and the cultivation of a more refined taste in street architecture generally. The great value of land, however, in the principal thoroughfares, forms the main obstacle to the carrying forward of improvements greatly needed in almost every direction. Many of the streets in the suburbs, and in the centre of the town, are occupied with the residences of the working classes, who, too frequently, seek to reside in as close proximity as possible to the manufactories in which they are employed. Each family, however, has a residence of its own, and the practice of living in cellars is here entirely unknown.

Birmingham.

Anterior to the Norman conquest Birmingham was a market-town, and probably to some limited extent its inhabitants were engaged in manufactures. Its proximity to the iron and coal districts of Staffordshire would afford great facilities to the workers in metals; but the arguments that have been made use of to show that it was a place of manufacturing celebrity in the times of the ancient Britons are so extravagant as to carry with them their own refutation. Notwithstanding its local advantages, the progress of the town must for a long period have been slow, as in the levy of men ordered to be made for the French war in 1346 Birmingham contributed but four, while Coventry supplied forty. Leland is the first writer who has left any description of the town on record. In the *Itinerary* (temp. Henry VIII.) he thus speaks:—"The beauty of Birmingham, a good market towne in the extreame parts of Warwickshire, is one street going up alonge almost from the left ripe of the brooke [the Rea], up a meane hill by the length of a quarter of a mile. I saw but one paroch church in the towne. There be many smithes in the towne, that use to make knives, and all manner of cutting tooles, and many lorimers that make bittes, and a great many naylors; so that a great part of the towne is maintained by smithes, whoe have their iron and sea-cole out of Staffordshire." Camden, who wrote half a century later, describes it as "swarming with inhabitants, and echoing with the noise of anvils (for here are great numbers of smithes)." The parochial registers, which commence in 1554, show that the population must at that period have been very limited, as the entries of deaths in the first six months amount to only 16, the marriages to 6, and the births to about 24. At the commencement of the following century, however, an increase was apparent; the burials in 1608 being 37, and in 1611, 64; the marriages in 1621 were 10, and in 1625, 17; and in 1627 the baptisms were 102.

In the unhappy contest between Charles I. and his parliament, the inhabitants warmly espoused the cause of the latter; and in 1642, when the king was on his march from Shrewsbury to relieve Banbury, they disarmed a guard who were conveying the royal plate and furniture to the camp, and sent their prize to Warwick Castle, one of the strongholds of their party. So devoted also were they to the cause they had espoused, that their workshops supplied 15,000 swordblades to Cromwell's soldiers, while no temptations could induce them to furnish a single weapon to the royalist forces. In 1643 they opposed Prince Rupert's entrance into the town, but were defeated with considerable loss; and the victors not only levied heavy contributions, but set the town on fire, eighty houses being consumed. In this fray the Earl of Denbigh lost his life. A more serious calamity, however,—the plague,—desolated the town in 1665, and the inhabitants were compelled to bury their dead in a lonely spot called Ladywood, at the outskirts of the town. No records remain to show the number of victims, the entries of burials in the parochial registers not exhibiting any increase over their ordinary numbers.

The revolution of 1688 was signalized by the total demolition of a Roman Catholic church and convent. These buildings had only been erected a few months; James II. having been a contributor of 125 tons of timber from the royal forest of Needwood. But the close of the eighteenth century was marked by an outbreak of so disgraceful a character as to have left an indelible stigma on the party at whose instigation it was excited. The strenuous efforts of the dissenters

Birmingham.

throughout the kingdom to obtain redress of the grievances under which they laboured, had been in no instance more zealously supported than by the Unitarians of Birmingham; and Dr Priestley, the minister of one of the meeting houses belonging to that body, by his arguments and satire, had excited against himself the hatred of the more violent members of the church party. The orthodox dissenters, while warmly sympathizing with the doctor's views relative to the connection of ecclesiastical establishments with the state, held aloof from him on account of his religious writings and opinions, and hence were not viewed with the same degree of dislike. On the 14th of July 1791, a dinner in commemoration of the French revolution was held at the Hotel, but as the public mind had been excited by an inflammatory handbill that had been extensively circulated, the company separated at an early hour. A mob assembled, however, and for three days held the town completely under their control, burning and pillaging the places of worship and private houses of the Unitarian body. The damage, at a moderate computation, was L.60,000; but of all the property destroyed no loss was so much to be deplored as that of Dr Priestley's laboratory and library, where the results of the doctor's scientific researches during a whole life were collected. The reputation of the town suffered for many years from the remembrance of this outbreak; but religious animosities by degrees subsided, as Dr Priestley, against whom the chief feeling was raised, never again resided in Birmingham.

When the great movement in favour of parliamentary reform was commenced in 1830, Birmingham took the lead, but notwithstanding the intensity of the political excitement, no breach of the peace occurred: and the working classes have on many occasions borne the reverses of trade, which have sometimes been severe, with exemplary patience. In 1839 when the people, at the instigation of trading political agitators, had abandoned those leaders in whose counsels they had previously reposed confidence an aimless outbreak occurred, and several houses in the market-place were destroyed.

The family of De Bermingham is supposed to have held the manor before the Norman conquest, and retained it after that epoch in dependence on the Norman lord of Dudley Castle. One of them engaged in the Barons' war against Henry III., and fell at the battle of Evesham in 1265; but under the Dictum de Kenilworth the estate was restored to his son. The last male representative was deprived of the family possessions through a conspiracy of John Dudley Duke of Northumberland, in 1527, who being desirous of obtaining the estate, contrived a pretended robbery by his creatures, in the presence of De Bermingham, when riding in the vicinity of the town; and who being tried and convicted as an accessary, was persuaded to surrender his estates to the crown, on promise of a pardon, and a small annuity. The act of parliament confirming the pardon still remains on the statute book. On the attainder of Northumberland, the manor lapsed to the crown, and was granted in 1555 to Thomas Marrow, of Berkswell, in the county of Warwick. The present owner is Christopher Musgrave, Esq. The value, however, is little more than nominal, as the market-tolls were purchased by the commissioners under the Street Act, whose powers were vested in the town-council by the Improvement Act of 1851. They now produce L.6400 per annum. The manorial residence, which stood near the parish church, and was surrounded by a moat, fell into decay after the ruin of the family; but the moat remained till 1816, when with other land it was appropriated to the purposes of a cattle-market.

From the earliest known period Birmingham was governed by two bailiffs, chosen at the court leet of the lord of the manor; but these officers, for several centuries, could have been but mere deputies of the lord, having no separate or independent powers. They were recognized authorities, however, as instances occur of writs of the crown having been directed to them as early as the time of Edward III. The duty of the high bailiff (who was generally a Churchman) was to convene public meetings, inspect the markets, and proclaim the fairs, two in number. The low bailiff (usually a dissenter) summoned the leet jury, on whom devolved the choice of the other officers. By the provisions of the Reform Bill, the elective franchise, with the privilege of returning two members to parliament, was conferred upon the town, the bailiffs being appointed returning officers. In 1839, a charter of incorporation was granted by the crown, but its validity was disputed, though ultimately confirmed by the legislature. In consequence of the various boards of commissioners retaining their authority undiminished, the powers of the corporation were of very limited extent; and it was not till 1851 that the conflicting views of the different bodies could be sufficiently harmonized to allow of a successful application to parliament for a bill consolidating the whole of the governing powers within the borough. By virtue of this act, all the rights and privileges formerly belonging to the different boards are now vested in the town-council; and the offices of high and low bailiffs are but a name. The revenue of the corporation is derived entirely from rates levied on the inhabitants.

Birmingham.

With the exception of the parish church of St Martin, Birmingham possesses no buildings of antiquity. A few half-timbered houses, with projecting eaves and pointed gables, of the time of James I., still remain in that portion of the town which Leland denominated "a pretty street"—Deritend; and part of a brick mansion of considerable size (also belonging to the Jacobean era) stands at the back of a retail shop in the High Street. The remembrance of the hospital or priory of St Thomas the Apostle is still preserved in several streets, bearing the names of Upper and Lower Priory, Minories, and Thomas Street, though the building itself was destroyed before the close of the sixteenth century; and the possessions of another establishment, of a semi-religious character, the Guild of the Holy Cross, were granted by Edward VI. for the purpose of endowing the grammar school now called after that pious monarch.

Until the year 1711, Birmingham proper possessed but one parish church, that of St Martin's, erected about the middle or towards the close of the thirteenth century. The interior has undergone considerable changes, many incongruous alterations having been made, while the exterior was cased with brick so far back as 1692, and presents, in consequence, a mean and uninviting appearance. The spire escaped this renovation, but having been constructed of a friable stone, was in so dilapidated a condition as to require to be taken down in 1853 preparatory to the erection of a new one. This elegant specimen of architectural skill was erected about the middle of the fourteenth century. The church contains some ancient monuments of the lords of Bermingham, and a curious one of an ecclesiastic, which were carefully restored in 1846. St Philip's church, consecrated in 1715, is in the Italian style, and the general effect is striking and beautiful. The churches of the establishment in the entire borough are twenty-five in number, eighteen having been erected within the last thirty years. Two new ones are also in course of erection (1854). The dissenting chapels are numerous, and some of them display evidence of superior taste. The members of the Roman Catholic body possess a cathedral and episcopal residence, a chapel, an oratory of St Philip Neri, a convent for Sisters of Mercy, adjacent to which is an asylum for destitute female servants, and a cemetery. There are also two public cemeteries of considerable extent, the grounds of which are laid out with great taste.

Until a recent period Birmingham was entirely destitute of public buildings having the smallest pretension to architectural beauty. But the deficiencies of former days are now being rapidly supplied. Chief among the ornaments of the borough is the town-hall, a splendid edifice in the Corinthian style. The most remarkable feature of this building is a series of fluted columns forty feet in height, which rest on a rustic basement, and support a bold entablature. The front elevation is

Birmingham.

terminated by a noble enriched pediment, and the general effect is exceedingly striking. The principal room in the interior is 145 feet long, 65 wide, and of the same height. It will accommodate about 4000 persons when seated, but double that number in a standing position. The decorations of the walls and roof are very rich. The building was commenced in 1832, and was opened for the first time in October 1834, on the occasion of the triennial musical festival for the benefit of the general hospital. The organ at the northern extremity of the hall is one of the finest in Europe, and was erected by public subscription. The cost of the hall, including land, was about L.40,000. The design was not entirely completed till 1850, the additional expense being L.12,000. The material employed is Anglesea granite. The market-hall commenced about 1830, is of Grecian design, having two large Doric, besides smaller entrances. It is 360 feet in length by 108 in width, and 60 in height, and is lighted by twenty-six windows on each side, with six at the north, and two at the south entrances, as well as by skylights. The roof is supported by seventeen series of beams, which rest on as many pairs of iron pillars 28 feet in height and 20 feet apart. In addition to stallage for more than 500 persons, there is sufficient space for 4000 persons to perambulate. The expense of the erection was L.30,000, but the site cost more than double that sum. Near the market-hall is placed the sole statue of which Birmingham can at present boast, erected in 1809 to the memory of Lord Nelson. The public office—the only building belonging to the town in which public meetings could be held before the erection of the town-hall—is in the Ionic style: having been considerably enlarged in 1830, it now contains numerous apartments in which much of the public business is transacted. The town prison is situated at the back of this building. The borough jail, which was built by the corporation, is very capacious, inclosing within its boundaries seven acres of land, and containing accommodation for more than 300 prisoners. The separate system of prison-discipline is here carried out. Adjacent to the jail is the lunatic asylum, in which 350 patients can be accommodated. This building was also erected by the corporation, who have likewise established a set of baths. A new workhouse, under the supervision of the guardians of the poor, was opened in 1852, and the total expense incurred in the erection of these four edifices has been upwards of L.150,000. A plan of sewerage is also being carried out, which will involve an expenditure equal to that just named. Bingley Exhibition Hall, in the Roman-Doric style, erected in 1850 by share subscription at a cost of L.7000, for the accommodation of the great cattle and poultry shows held annually in the town, is about 224 feet long by 212 wide, and covers 1¾ acre of land. These exhibitions, which were commenced in 1849, are held in the month of December, and have already attained so great a degree of celebrity as to rival those of the London Smithfield Club held about the same period, and have given a stimulus to the establishment of similar societies throughout the kingdom. The number of visitors is generally from 40,000 to 50,000. A corn-exchange has also been recently erected by private enterprise for the use of agriculturists and others attending the markets. There are also, in addition, a school of design, post-office, theatre, news-room, subscription libraries, and other minor public edifices. With the exception of the polytechnic institution, which is a mechanics' institute, there is no institution for the promotion of science, but the corporation having granted a site of land for the purpose. Buildings for a Midland Literary and Scientific Institute on an extended scale are about to be erected. A statue of the late Sir Robert Peel by a native artist—Mr Peter Hollins—will also be placed in some public thoroughfare of the borough in the course of the present year (1854). A flourishing society of artists, holding an annual exhibition of pictures, has been in existence in the town for eleven years. Street architecture has considerably advanced of late, many of the retail shops and offices being erected in a style of magnificence worthy the important community amongst which they are situated. There is also a botanic garden with extensive conservatories at Edgbaston.

The educational establishments of Birmingham are varied and flourishing. The free grammar school, founded by Edward VI. in 1552, is a noble institution, affording gratuitous instruction in its chief and branch schools for nearly 2000 young persons. The revenues are derived from lands formerly the property of a semi-religious fraternity dissolved at the Reformation, and called the "Guild of the Holy Cross." These possessions, originally of the value of L.21 per annum, are to a great extent situated in the principal thoroughfares of the town; and as much of the land has been let on building leases, the expiry of these has augmented the income of the charity from L.3300 in 1827, to L.10,000, and this sum will in a few years be considerably increased. About 460 boys are taught in the chief school; and nearly 1600 of both sexes in four branch establishments. The school, which was erected from the designs of Mr Barry, is in the perpendicular Gothic style, 174 feet long and 60 feet high. The front elevation consists of two stories, with traceried windows, and is divided into compartments by buttresses, which terminate, above an embattled parapet, in pinnacles enriched with crockets and finials. The building cost, including the expense of additional land for the site, L.71,000. In consequence of this great outlay, and the establishment of an extended and more liberal system of education, the debts of the charity amounted to L.98,000, but the whole of this sum has been paid from the proceeds of sales of land to the railway companies. The tercentenary anniversary of the foundation of the school was celebrated in April 1852 with great *éclat*. The Queen's College (which had its origin in a school of medicine, founded in 1828) obtained a royal charter in 1843, and is a flourishing institution. Though originally limited to medical students only, it has now its departments of arts, law, and engineering, and has an efficient staff of highly talented professors. Affiliated to the institution is the Queen's Hospital, erected in 1840. The collegiate buildings, which have but a limited frontage, are in the perpendicular style, but the effect of the façade is greatly impaired by the proximity of adjacent houses. The Blue-Coat school, founded in 1724, supports and educates from 200 to 300 boys and girls, who are trained in the principles of the Established Church, and apprenticed at the age of fourteen. The annual income is about L.2500. There is also a Protestant-dissenters' charity-school, supported chiefly by the Unitarian body; and a large and flourishing free industrial school, besides numerous minor ones. In 1831 a proprietary school was established at Edgbaston, the building being a handsome Elizabethan structure. There is a college also, established in 1838, belonging to the Congregationalists: the number of students is about twenty. In the vicinity of the town, a training college for the diocese of Worcester, and a reformatory institution for juvenile criminals, have likewise been recently established. The census returns of 1851 show the number of day-schools in the borough to be 454, of which 66 are public and 388 private; scholars on the books, 22,183, and in actual attendance, 17,985; while of Sunday-schools the number is 70, and of scholars on the books, 21,406, and in actual attendance, 14,376. The proportion of children attending school to the entire population, is, of day-scholars, 1 in 11·02, and of Sunday-scholars, 1 in 10·42.

The charitable institutions of the town are numerous and important. They consist of two hospitals, which administer relief to 20,000 out-patients, and 3700 in-patients annually; a general dispensary; a lying-in hospital; and a variety of other benevolent institutions. A savings-bank, with 23,674 depositors, and L.421,574 invested in government securities, has been in operation for 27 years.

To the staple commodities of iron manufacture, brass goods were added about the seventeenth century. This branch now forms one of the most important in the town. Every description of article in this metal is produced in immense quantities both for the home and foreign markets. Metallic bedsteads in brass and iron—this department being exclusively cultivated by some of the largest houses—chandeliers, gas-brackets, cornice-poles, ornamental railings, metallic picture frames, and curtain bands; in addition to the humble but not less useful articles of door-knobs, candlesticks, and hinges, find employment for many thousands of men, women, and boys. The universal application of steam-power has led to the invention of numerous contrivances for economizing labour, and the result has been a greatly augmented faculty of production, which, by diminishing the cost of manufacture, has materially increased the demand. Another result has been that many branches of labour are now brought within the range of female industry; and it was given in evidence before a government commissioner in 1841, that in one manufactory in the button trade the proportion of females to males was ten to one; while in another, in the same trade, the numbers were 60 males and 300 females. Nearly one-half

Birmingham

of the married females are engaged in factory labour; the percentage of deaths of children under five years of age is 48, or nearly one-half of the entire number registered in the whole borough. This awful rate of mortality can only be accounted for by the fact just adverted to. Among the more elegant productions of the brassfoundry trade may be classed the manufacture of lamps. These tasteful articles are produced in immense quantities: enamelled and gilt glass entering largely into their composition. The buckle trade, for which Birmingham was at one time so famous, has entirely disappeared; and the manufacture of metal buttons has considerably diminished, in consequence of the general substitution of Florentine ones. The glass trade (including stained glass for windows) is very successfully cultivated; and in the vicinity of the town is the gigantic establishment of Messrs Chance, who supplied the whole of this material required for the glazing of the Crystal Palace for the Exhibition of 1851. In near proximity also is the immense foundry of Messrs Fox and Henderson, the contractors for the erection of the entire building. The wondrous process of electro-plating, which has sprung up entirely within the last few years, is now carried on to an almost incredible extent. The manufactory of Messrs Elkington is the parent establishment in the town; and articles of the most dazzling description, and in immense variety, are produced. Jewellery, in the fabrication of which female labour largely enters, is made in great quantities. Of steel pens fully seven hundred millions are annually sent into the market. The consumption of steel in the establishment of Mr Gillott for 1853 was 90 tons; the number of pens manufactured, 261,273,600. The papier-maché trade is cultivated very extensively. Many of the articles composed of this material, consisting of sofas, tables, and other kinds of furniture, in addition to the smaller descriptions, such as desks, workboxes, and inkstands, are ornamented with figures, flowers, and landscapes, in a good style of art, and inlaid with pearl—the effect produced being exquisitely beautiful. The gun trade, first stimulated by government patronage in the time of William III., retains its pristine reputation; and a proof-house, where all gun-barrels manufactured are required to be proved, was established by an act of parliament in 1813. The ordnance department of government have also an establishment in the town. Metal-rolling, wire-drawing, and pin-making, are extensively carried on; but to enumerate more than a few of the more important trades, where the entire number is 250, were unnecessary. The great agent of production, the steam-engine, was introduced in 1767 by Mr Boulton, who, in conjunction with his partner James Watt, acquired so wide a celebrity. The Soho, two miles distant from the town, where the manufacture was formerly carried on, is now dismantled; but the successors of the firm still conduct the business at Smethwick, a thriving locality in the neighbourhood. The steam-power in the borough is nearly equal to that of 6000 horses, or 90,000 men.

The town was first lighted with gas in 1819. There are now two companies, whose annual production amounts to more than 300,000,000 cubic feet; and many of the larger establishments manufacture their own supply. Canals were first introduced in 1767, and are still used to a considerable extent, notwithstanding their formidable rivals the railways. The Grand Junction, connecting the town with Liverpool, was the first line of railway completed to Birmingham, having been opened in July 1837. This was followed by the London and Birmingham in the following year, and subsequently by the Derby, and Gloucester. For a considerable period the various lines had separate stations, but the inconvenience arising from this cause has been remedied, and all the old lines now unite at one point, in New Street. The length of the great central station (now nearly completed) is more than 1100 feet, the width varying from 188 to 211 feet. The structure (with the exception of the necessary offices, which are of white brick) is composed of iron; and the roof, forming a segment of a circle, is covered with fluted glass. Beneath the span of this immense fabric are ten lines of rails, four platforms for passengers, and a roadway for cabs; but though the span is so great, the roof is unsupported by a single pillar except those on either side. The Stour Valley trains depart from this station; and the whole of the passenger traffic of the London and North-Western and Midland lines will be transferred to it in the course of the present year (1854). The Oxford junction, a line belonging to the Great-Western Company, furnishes a second route to the metropolis; and for this, in conjunction with the Dudley and Wolverhampton, a large station will be erected on Snow Hill. The destruction of house property for the purposes of the different lines has been immense; in one instance the whole of one side of a street a mile in length having been removed.

Biron || Biscay.

In 1801, the population of Birmingham was 73,670; in 1811, 85,755; in 1821, 106,721; in 1831, 142,251; in 1841, 182,922; and in 1851, 232,841, of whom 113,916 were males, and 118,925 females. The number of persons to a square mile is 41,853, being greater than that of any other town in England except London and Liverpool. The area in statute acres is 7831, and the rateable property is assessed at L.655,621. The number of houses in 1841 was 30,291, and in 1851, 48,892. The increase, however, would have been much more considerable but for the cause already stated. (A. D—N.)

BIRON, Armand de Gontault, Lord of, marshal of France, and a celebrated general in the sixteenth century, who signalized himself by his valour and conduct in several sieges and battles. He was made grand master of the artillery in 1569; and so much was he respected or feared on account of his valour, that nobody dared to assault him at the massacre of St Bartholomew. He was the first who declared for Henri IV.; brought a part of Normandy under his subjection; and dissuaded him from retiring to England or Rochelle. Biron was killed by a cannon-ball at the siege of Epernay, July 26. 1592, at the age of sixty-eight. He was a sort of universal scholar; and used to carry a pocket-book, in which he noted everything that appeared remarkable. This gave rise to a proverb at court, when a person happened to say anything uncommon, "You have found that in Biron's pocket-book."

Biron, *Charles de Gontault*, created duke of Biron by Henri IV., was a man of great intrepidity, but fickle and treacherous. In 1601 he was sent as ambassador to the court of Queen Elizabeth to announce his royal master's marriage with Mary of Medici; but being discovered in a treasonable correspondence with Spain, he was beheaded in the Bastille at Paris, July 31. 1602.

BIRS NIMRUD. See Babylon.

BISACCIA, a city in the Principato-Ulteriore of the kingdom of Naples. It is a bishopric in conjunction with St Angelo, and contains 5500 inhabitants.

BISACUTA, in the middle-age writers, an axe with two edges, to cut either way; or a missile weapon pointed at both ends. Walsingham represents the *securis bisacuta* as peculiar to the Scottish nation.

BISCARA, a town of Algeria, capital of the southern province of Zaab, and about 200 miles S.E. of Algiers. It is now in the possession of the French. Pop. about 4000.

BISCAY (Vizcaya) Seignory of, one of the three *Provincias Vascongadas* or Basque provinces in the north of Spain. It is bounded on the north by the Bay of Biscay, east by Guipuzcoa, south by Alava, and west by Santander. Area 1272 square miles; pop. (1850) estimated at 150,000. The surface is highly picturesque, being very mountainous, and diversified with numerous narrow valleys and fertile plains. The mountains are generally covered with forests to their summits, while others consist almost entirely of naked calcareous rock. This province is well cultivated, and produces wheat, maize, barley, rye, flax, chestnuts, grapes, peaches, and other fruits. The farms are generally small, but are cultivated with great care, and almost entirely by manual labour. Among its forest-trees are the oak, holly, arbutus, and chestnut; and furze and heath abound in the poorer parts. The wild-boar, lynx, fox, and other beasts of prey, are still found in several of the forests; and deer, rabbits, partridges, woodcocks, and other kinds of game, are plentiful. The principal river is the Nervion or Ibaizabal, on which the capital, Bilbao, is situated: it has, besides, several smaller rivers, and numerous mountain streams. The coast presents a bold and rugged aspect, and in several places is deeply indented. Its

Biscay || Bishareen.

principal ports are Portugalete at the mouth of the Nervion, Plencia, Bermeo, and Hea. Biscay is very rich in minerals. Iron of the finest quality is found in almost every part of the province; and marble, lime, and sandstone, are abundant. The Biscayans, who represent the ancient Cantabrians, are an industrious, bold, and hardy race; primitive in their manners, as well as gay, friendly, and hospitable. They are characterized by an innate love of freedom, and an intense jealousy of everything having the appearance of an encroachment upon their liberties. In manners and habits they have a considerable resemblance to the Irish, and were supposed to be of the same Celtic origin; but the Basque is not a Celtic language.

The manufacture of iron is the chief branch of industry, but at present it is less flourishing than formerly, though their gun-barrels are still in high repute. Among the other manufactures are porcelain, linens, hats, copper and brass wares, straw and rush chairs, ropes, leather, &c. The fishings are actively prosecuted along the coast. The earliest whale-fishery of Europe was pursued on this coast by the hardy Biscayans; but the whale has long ago retired farther to the north, and deprived them of this species of industry.

The Cantabrians in the time of the Romans were a fierce and warlike people, and were only subdued after a severe struggle by Augustus. This province afterwards fell successively into the hands of the Suevi, Franks, and Goths; and it formed for some time an independent lordship. In the fourteenth century it came into the power of the king of Castile, and since that time it has formed a part of the Spanish kingdom. Although subject to Spain, the Biscayans still maintain a republican form of administration, nominating their own governors and magistrates, regulating the amount of taxation, &c. The term Biscay is frequently used as synonymous with Basque, to include the three Basque provinces.—Madoz, *Dic. Geograf. de España.*

Biscay, *Bay of*, an extensive gulf or bay of the Atlantic, between the northern coast of Spain and the western coast of France. It extends from the island of Ushant, off Brest, to Cape Ortegal on the north coast of Galicia. The Spanish coast is almost wholly bold and rocky; the French is more varied, and from the mouth of the Gironde southward to the Adour is low and sandy. The openness of this bay, the strong westerly winds, and the current (Rennel's) which sets in from the west and sweeps along its southern and eastern shores, impede its navigation. It receives the waters of the Loire, Charente, Gironde, and Adour.

BISCEGLIA, a fortified seaport of Naples, in the province of Terra di Bari, situated on a rocky promontory on the Adriatic, 21 miles W.N.W. of Bari. It is the seat of a bishopric, and has a cathedral, numerous churches and convents, a hospital, and a theatre. Its harbour is only accessible to small vessels, and it has little trade. Being destitute of springs, it has numerous reservoirs for the collection of rain-water. Pop. 14,000.

BISCHOP, or Biskop, John de, an artist, born at the Hague in 1646. He excelled in making copies of the pictures of the great masters; but he is best known as an engraver. His works are chiefly etchings, harmonized with the graver; and though slight, yet free, spirited, and pleasing. He worked chiefly at Amsterdam, where he died in 1686.

BISCHWILLER, a town of France, capital of a canton of the same name, department of Lower Rhine, 14 miles north of Strasburg. It has manufactures of woollen and linen stuffs, oil, soap, earthenware, &c., and some trade in hops, hemp, leather, and tobacco. Pop. (1846) 6242. Its fortifications were destroyed by the imperialists in 1706.

BISCUIT. See Baking.

BISHAREEN, the name of several tribes inhabiting the desert on the western side of the Red Sea, as far north as Lat., 21°, and south to the Taccaze, a branch of the Atabara, the ancient Astaboras. According to Burckhardt, they are not of Arabian origin, although they have the manners of the Bedouins; but, like their more polished neighbours the Abyssinians, they devour raw flesh.

Bishop.

BISHOP, one of the superior order of pastors in the Christian church, consecrated for the spiritual government of the ordinary pastors in a certain district or diocese. The word comes from the Saxon *bischop*, which again is derived from the Greek ἐπίσκοπος, an *overseer, inspector,* or *superintendent,* a title given by the Athenians to those whom they sent into the provinces subject to them, to see whether everything was kept in order. The Romans applied the same designation to those who were appointed inspectors of bread and provisions.

A bishop discharges the same relative functions as an archbishop, though of course in a lower sphere. An archbishop with bishops consecrates a bishop; a bishop with priests ordains a priest; the archbishop visits a province, the bishop a diocese; the archbishop convocates a provincial synod, the bishop a diocesan one; and the archbishop has canonical authority over all the bishops of his province, the bishop over the priests in his diocese.

The election of bishops was anciently placed in the clergy, and the people of the parish, province, or diocese; but afterwards, princes and magistrates, patriarchs, and popes, usurped the power. The election was required to be within three months after the vacancy of the see; and the bishop to be chosen from among the clergy of that church. Formerly the bishop claimed a share in the election of an archbishop; but this was set aside by the popes.

In England, during the Saxon times, all ecclesiastical dignities were conferred by the king in parliament. At length, however, after several contests, especially between Archbishop Anselm and Henry I. in consequence of a grant of King John, recognised in Magna Charta, and established by the 25th Edw. III., stat. 6, § 3, bishops were elected by the chapters of monks or canons—some shadow of which still remains in the present method of disposing of bishoprics; but by the 25th Henry VIII. cap. 20, the right of nomination was restored to the crown.

Ordinarily, three bishops at least are required in the ceremony of consecrating a bishop; but in some cases one bishop will suffice. The English succession of Protestant bishops stands on this last ground. In England, the king being certified of the death of a bishop by the dean and chapter, and his leave requested to elect another, the *congé d'élire* is sent to them, with a letter missive, nominating the person whom he would have chosen. The election is to be within twelve days after the receipt of it, otherwise the king by letters patent appoints whom he pleases; and the chapter, in case of refusing the person named by the king, incurs a *præmunire.* After election, and its being accepted by the bishop, the king grants under the great seal a mandate for confirmation, which the bishop consigns to his vicar-general. This consists mostly of a solemn citation of such as have any objections to the bishop-elect, a declaration of their contumacy in not appearing, and an administration of the oaths of allegiance and supremacy, of simony, and canonical obedience. Sentence being read by the vicar-general, the bishop is installed in the province of Canterbury by the archdeacon; the fact is recorded by a public notary; and the bishop is invested with full powers to exercise all spiritual jurisdictions, though he cannot sue for his temporalities till after consecration. Then follows the consecration by the archbishop or some other bishop appointed by lawful commissions, and two assistant bishops. The ceremony is much the same as in the Roman Catholic church, save that after investiture in the episcopal robes, the archbishop and bishops lay their hands on the new prelate's head, and consecrate him with a certain form of words. The process of the translation of a bishop to another bishopric differs only in this, that there is no consecration. The age of a bishop is to be at least thirty years; and, by the ancient discipline, none were to be chosen but

Bishop.

those who had passed through all the inferior orders; but in some cases of necessity this was dispensed with, and deacons, nay laymen, were raised at once to the episcopal dignity.

The form of consecrating a bishop is different in different churches. In the Greek church, the bishop-elect being by the assistant bishops presented for consecration, and the instrument of election put in his hand, after several prayers, the first of which is called *diaconicum*, he demands consecration; and after making profession of his faith, he receives a benediction. He is then interrogated as to his belief of the Trinity; to which he answers by a long profession of faith, and receives a second benediction. Lastly, his opinion regarding the incarnation is demanded; to which he answers in a third profession of faith, which is followed by a third benediction; after which the consecrator gives him the pastoral staff. He is then led up to the altar, where, after certain prayers, and three crosses on his head, he receives the *pallium*, if he be an archbishop or patriarch; then the kiss of peace from his consecrator and two assistants; and sitting down, he reads, prays, and gives the communion to his consecrator and others.

In the Roman Catholic church, the bishop-elect, being presented by the elder assistant to the consecrator, takes the oath; he is then examined as to his faith; and after several prayers, the New Testament is drawn over his head, and he receives the chrism or unction on his head. The pastoral staff, ring, and gospel, are then given him, and after communion the mitre is put on his head; each ceremony being accompanied with suitable prayers. The consecration ends with the *Te Deum*. These last-mentioned ceremonies are laid aside in the consecration of English bishops. Nevertheless, the book of consecration set forth in the time of Edward VI. and confirmed by act of parliament, in which some of them are enjoined, is declared to be the standard for this purpose by the thirty-sixth article.

The function of a bishop in England may be considered as twofold, namely, what belongs to his order, and what belongs to his jurisdiction. To the episcopal order belong the ceremonies of dedication, confirmation, and ordination. By the common law, the bishop is to certify the judges touching legitimate and illegitimate births and marriages; and by that and the ecclesiastical law he is to take care of the probate of wills and granting administrations, to collate to benefices, grant institutions on the presentation of other patrons, command induction, order the collection and preservation of the profits of vacant benefices for the use of the successors, defend the liberties of the church, and visit his diocese once in three years. To the bishop also belongs the power of suspension, deprivation, deposition, degradation, and excommunication.

The incomes of the various sees till of late differed exceedingly in amount; but the ecclesiastical commissioners for England have adjusted, or are now adjusting, these to a nearer approach to equality. They have assigned or contemplated fixing the income of the archbishop of Canterbury at L.15,000; that of the archbishop of York at L.10,000; London, Durham, and Winchester, at L.8000; and the rest at from L.5500 to L.4500.

All bishops of England are peers of the realm, except the last consecrated; and, as such, sit and vote in the House of Lords. They are barons in a threefold manner; feudal, in regard to the temporalities annexed to their bishoprics; by writ, as being summoned by writ to parliament; and lastly, by patent and creation. Accordingly, they have the precedence of all other barons, vote as barons and bishops, and claim all the privileges enjoyed by the temporal lords; excepting that they cannot be tried by their peers, because in cases of blood they themselves cannot pass upon the trial, for they are prohibited by the canons of the church from being judges of life and death. They have the title of *Lords* and *Right Reverend Fathers in God* in England. Besides two archbishops, there are twenty-five bishops, exclusive of the bishop of Sodor and Man. The bishops of London, Durham, and Winchester, take precedence of other bishops, who are to rank after them according to their seniority of consecration. In Ireland there are two archbishops and twelve bishops. In Scotland, before the Presbyterian establishment, there were two archbishoprics and twelve bishoprics. The bishops of the Scottish Episcopal, and of the Roman Catholic church, are not recognized by the state.

Bishop's Court || Bishop's Castle.

The following is a return of the number of colonial bishops, stating the salaries of each, and sources whence those salaries are derived, made to the House of Commons 11th June 1852:—

Diocese.	Salary.	From what source derived.
	L.	
Quebec	1990 *	Imperial parliamentary vote.
Toronto	1250	Clergy reserves in Canada West.
Montreal.....	800	Colonial Bishoprics Fund; the interest of investments in the colonies, and in this country.
Nova Scotia	550	Trust funds held by the Society for the Propagation of the Gospel, and the rent of a farm in Nova Scotia.
Frederickton	1000	Colonial Bishoprics Fund.
Newfoundland	1200	L.700 Imperial parliamentary vote. L.500 Society for the Propagation of the Gospel.
Rupert's Land	700	The interest of a bequest by the late James Leith, Esq., and an annual allowance by the Hudson's Bay Company.
Jamaica	3000	Consolidated fund.
Barbadoes ...	2500	ditto
Antigua	2000	ditto
Guiana	2000	ditto
Sydney	1500	General Colonial Revenue, under Schedule (C.), annexed to Act 5th and 6th Vict. cap. 76.
Melbourne ...		L.500 Colonial Treasury. L.333, 6s. 8d. Colonial Bishoprics Fund.
Newcastle ...		L.500 Colonial Treasury. L.333, 6s. 8d. Colonial Bishoprics Fund.
Adelaide.....	800	Colonial Bishoprics Fund; interest of monies invested in the colony and in this country.
Tasmania ...	800 L.200 for house allowance, also forage allowance.	Part from colonial funds, and interest of L.5000 invested in securities in the colony by the Colonial Bishoprics Fund.
New Zealand	1200	L.600 Imperial parliamentary vote. L.600 paid by the Church Missionary Society to the Colonial Bishoprics Fund.
Cape Town...	800	Colonial Bishoprics Fund; interest of monies invested in the colony and in this country.
Colombo	2000	Colonial Funds.
Victoria	1000	Colonial Bishoprics Fund.
Gibraltar ...	1200	Colonial Bishoprics Fund.

* This includes the salary to the Bishop as rector of the parish.

Bishop's *Court*, an ecclesiastical court, held in the cathedral of each diocese, the judge in which is the bishop's chancellor, who decides according to the civil and canon law; and if the diocese be large, he has his commissaries in remote parts, who hold what are called *consistory courts*, for matters limited to them by their commission.

Bishop Auckland. See Auckland Bishop.

Bishop's Castle, a market and borough town in the hundred of Purslow and county of Salop, on the declivity of an eminence on the river Clun, 159 miles from London. Being

Bishop's Stortford || Bissagos.

on the main road between England and Wales, it has some trade, especially at its market, which is held every Friday. The town-house is a neat structure, as is also the church, which stands below the town. The bishops of Hereford had formerly a castle here. Pop. in 1851, 1699.

BISHOP'S STORTFORD, a market-town of the hundred of Braughin, in the county of Hertford, 32 miles from London. It is situated on the banks of the river Stort, and consists of four principal streets. By means of the canal it communicates with the metropolis, to which it sends much malt, corn, &c. Market-day Thursday. Pop. (1851) 5280.

BISHOP'S WALTHAM, a market-town in the hundred of the same name, county of Southampton, 65 miles from London. Here are the remains of the palace of the bishops of Winchester, and of the forest of Waltham. Principal trade, leather. Market-day, Friday. Pop. of parish (1851) 2265.

BISHOP'S WEARMOUTH, a large parish adjoining the town of Sunderland, in the county of Durham. Pop. (1851) 31,824. See SUNDERLAND. It stands on the Wear, and has several manufactories of different kinds. Over the Wear there is a magnificent iron bridge 236 feet in length, consisting of a single arch.

BISHOPING, a term to denote the devices used by horse-dealers to make an old horse appear young, or a bad one seem good.

BISIGNANO, a city and bishop's see, province of Calabria Citeriore, in the kingdom of Naples, 15 miles N. of Cosenza; pop. 3200. It has a castle, a cathedral, and several churches, with some trade in silk.

BISLEY, a market-town in the county of Gloucester, 103 miles from London. It is situated in the vale of Chalford (where the manufacture of broad cloth is extensively conducted), and is irregularly built. The Stroud Canal, which unites the Thames and Severn, passes through the parish. The church is handsome, and stands on a conspicuous eminence. Pop. (1851) 4801.

BISMILLAH, a solemn form used by Mahommedans at the beginning of all their books and other writings, signifying, "In the name of the most merciful God."

BISMUTH, one of the metals. See CHEMISTRY. By imparting hardness, it is a useful compound in the formation of several metallic alloys, as in the fabrication of printers' types, and the composition of foreign pewter. Eight parts of bismuth, five of lead, and three of tin, constitute what is called, after its discoverer, Newton's metal, which melts at the heat of boiling water, and may be fused over a candle in a piece of stiff paper without burning the paper. Plumbers' solder consists of one part of bismuth with five of lead and three of tin. With an equal weight of lead, it forms a brilliant white alloy, much harder than lead, and more malleable than bismuth, though ductile; and if the proportion of lead be increased, it is rendered still more malleable.

BISOMUM (*bis* and *σῶμα*), or DISOMUM, in *Roman Antiquity*, a sarcophagus or tomb, for two dead bodies, or their ashes. The sepulchres of the primitive Christians were inscribed with the words *bisomi*, *trisomi*, *quadrisomi*, &c., to indicate the number of bodies deposited in them.

BISON. See MAMMALIA, *Index*.

BISSAGOS, a group of small, low, fertile islands, situated at or near the mouth of the Rio Grande, in Western Africa. The entire number of these islands is very great, but there are only sixteen of any considerable magnitude. These are, Bissao, Bulama, Jate, Bussi, Manterre, Canabac, Galpineis, Arcas, Formosa, Carache, Corbelle, Genthera, Cavallo, Mel, Casegu, and Cove. The first five are mere alluvial islands, separated by river-branches from the continent, of which they properly form part. The others lie twenty or thirty miles out at sea, extending in a north-westerly direction towards the Gambia. Among the many smaller islands may be mentioned Bourbon, Sarcieri, Poelon, Papaygo, and Los Poarcos. Along the exterior side of these islands, where they face the ocean, extend numerous banks, which render the navigation very dangerous.

Bissat || Bitche.

These islands produce abundantly millet, rice, and fruits, and are all well stocked with a peculiar breed of oxen with a hump on the back, and remarkable for size and strength. The inhabitants, who are tall and robust, are fierce and warlike. This character applies to the Papels, who occupy Bissao and the adjoining continent, and still more to the Bissagos or Bijugas, who possess most of the remaining islands. They have almost entirely driven out the Biafaras, a mild and industrious race, who have been obliged to seek refuge on the continent along the banks of the Rio Grande. In 1792 some English adventurers formed the Bulama association, with the view of forming a settlement on the island of that name; and on the 11th April three vessels with 275 colonists sailed for Africa, under the command of Mr Dalrymple. They sailed to Bulama, and were quietly taking possession of the island, when the Bissagos from Canabac attacked the party, and killed several of their number. Mr Dalrymple then retired to Bissao, and induced the king of Canabac, for a trifling consideration, to cede to Great Britain the island of Bulama. A settlement was then effected; but finding that, instead of being placed in a situation of ease and luxury, they were obliged to cultivate the soil, the colonists lost courage, and most of them returned home in the vessel which brought them to Bulama. Captain Beaver being now left with little more than twenty men, and only half of these effective, was attacked by the king of Canabac. The enemy was gallantly beaten off; but the difficulties and distresses of the colony continuing to increase, Beaver took the first opportunity of conveying the remnant of his colony to Sierra Leone.

BISSAT, PATRICK, descended from the earls of Fife in Scotland, was born in that county in the reign of James V. From the university of St Andrews he removed to that of Paris; and he afterwards proceeded to Bologna, where he was appointed professor of canon law. Having filled this office for several years with great reputation, he died in 1568. He was also distinguished as an orator, a poet, and a philosopher. *Patricii Bissatti Opera omnia* were published at Venice in 1565, 4to.

BISSEXTILE, a year consisting of 366 days, corresponding to leap year. See CALENDAR, *Solar Year*.

BISTOURY (French *bistouri*, from the city Pistoia), a surgical instrument for making incisions. Some have the form of a lancet, others are straight and fixed in the handle like a knife, and others are crooked, with the sharp edge on the inside.

BISTRE (French *bis*, brown), a pigment of a brown transparent colour, which is best prepared from the soot of beech-wood, by boiling it in water (in the proportion of two pounds to a gallon) for half an hour. After standing to settle, and while still hot, the clearer part is poured off, and evaporated to dryness. The residuum is bistre.

BISUTUN, or BESSATUN, the plateau of Kermanshaw, the plain of the ancient Media. Its northern boundary is a precipitous ridge, generally 1500 feet above the plain. On this natural escarpment, Sir R. Ker Porter found the remains of a remarkable bas-relief, representing a Median king or warrior passing sentence on nine captives before him, while one prostrate at his feet is in the act of imploring mercy with outstretched hands. In another portion of this surface are the remains of a Greek inscription, that has been nearly effaced by a Persian one of modern date.

BISZTRITZ, a fortified town of Transylvania, pleasantly situated on a river of the same name, in Long. 24. 34. E. Lat. 47. 5. 46. N. It has several churches, a gymnasium, and other schools, a considerable trade in cattle, and about 6000 inhabitants.

BITCHE, a town and fortress of France, department of

Moselle, and capital of a canton of the same name. It stands in a pass of the Vosges, and the citadel occupies the summit of an almost inaccessible rock in the centre of the town. It mounts 80 pieces of cannon, and is regarded as almost impregnable. It has manufactures of earthenware, with extensive glass-works in the vicinity. Pop. 3131.

BITHYNIA (Βιθυνία), a province in the N.W. of Asia Minor, stretching along the Propontis, the Thracian Bosporus, and the Euxine, between the rivers Rhyndacus in the west, and the Parthenius in the east. In the south it bordered on Galatia and Phrygia Epictetus. The country derived its name from its inhabitants, the Bithyni, whose original home was the country about the Strymon in Thrace. Remnants of this nation remained in Thrace, and are frequently spoken of under the name of Thyni, or Thraces Bithyni. On their arrival in Asia, they expelled or subdued the native tribes of the Mysians, Bebryces, Caucones, and Mygdones; the Mariandyni, however, maintained themselves on the coast in the north-eastern part of the country. The Bithyni, after their conquest of the new country, appear to have been divided into two branches, the Thyni on the coast about the river Sangarius, and the Bithyni in the southern parts of the country. In the reign of Crœsus, Bithynia was incorporated with the Lydian empire, together with which it soon after fell into the hands of the Persians. Under the dominion of the latter, who probably made no great changes in the constitution of the country, it was governed by the Satrap of Phrygia; for at that time it scarcely contained any towns except the Greek colonies of Chalcedon and Astacus. During the subsequent disturbances in the Persian empire, some native princes of the Thyni made themselves independent, and maintained this independence even against Alexander the Great and his successors. Nicomedes, the first who assumed the title of king, reigned until B.C. 246. His successor, Prusias I., who died in B.C. 192, and Prusias II. (who probably died in B.C. 150) did much to establish the kingdom on a firm basis, and to extend its boundaries. The last king, Nicomedes III., in B.C. 75, bequeathed his kingdom to the Romans, who at first united it with their province of Asia, and afterwards with Pontus, until Augustus constituted it as a separate proconsular province. At the same time that emperor united the western part of Paphlagonia, under the name of Pontus, with Bithynia. Theodosius II. again divided the province, restricting the name of Bithynia to the western half, which contained the cities of Nicomedia, Nicaea, and Chalcedon, while the eastern part, with the cities of Heraclea and Claudiopolis, received the name of Honorias.

The country of Bithynia is traversed in all directions by woody mountains, the highest of which is the Mysian Olympus, which furnished abundance of timber for shipbuilding. The plains and valleys are very beautiful and fertile, producing barley, wheat, beans of various kinds, figs, and wine, but no olives. The district about Bithynium was distinguished for its excellent pasture; and the cheese made there was in great repute among the ancients. The principal river was the Sangarius, traversing the country from south to north. (See Cramer, *Asia Minor*, i. 167–215; Leake, *Asia Minor*, p. 306; Forbiger, *Handbuch der Alten Geographie*, vol. ii. p. 374, where all the ancient authorities referring to Bithynia are cited.) (L. S.)

BITLIS, a town of Asiatic Turkey. See BETLIS.

BITONTO, a city, the see of a bishop, in the province of Bari, in the kingdom of Naples, on the great road from Foggia to Bari. It contains, besides the cathedral, twenty-four churches, and 14,500 inhabitants, who export the excellent wine known by the name of Zagarello.

BITTERFELD, a walled town of Prussia, capital of a circle of the same name, in the province of Saxony and government of Merseburg. It is situated on the river Löber, near the Mulde, and has manufactures of woollen cloth and hardware. It was founded by a colony of Flemings in the twelfth century. Pop. (1849) of town 3890, of circle 44,625.

BITTERN. See ORNITHOLOGY, *Index*.

BITTS, perpendicular pieces of timber fixed in the deck of a ship for fastening ropes to. There are also bitts to secure the windlass and the heel of the bowsprit.

BITUMEN (*Mineral Pitch, Asphaltum, Erdpech*), the most perfectly inflammable mineral known. Of this there are three varieties, elastic, earthy, and compact; the first is distinguished by its softness and elasticity, which, however, it partly loses on exposure to the air; the second, by its dull earthy appearance, and softness sufficient to take an impression from the nail; and the third, from its more or less conchoidal fracture, corresponding to the degrees of lustre it possesses. The component parts of these, however, are nearly the same; and, except in appearance and consistency, they do not differ from naphtha, a fine colourless fluid, which when first inspissated, becomes brown, and is then changed into mineral pitch by exposure to the air. Bitumen is usually of a black or brownish hue, is easily inflammable, and burns with a bituminous smell, much smoke, and a clear flame: some varieties even melt at a higher temperature. In specific gravity it varies considerably, from 0·828 to 1·160 according to its density; and in composition it consists chiefly of hydrogen and carbon. The substance called petroleum is a liquid bitumen, apparently formed of asphaltum dissolved in naphtha. The elastic variety has been found principally in the Odin mine at Castleton, in Derbyshire; and from its property of taking up the traces of a pencil in the same manner as Indian-rubber, it has obtained the appellation of *mineral caoutchouc*. The semi-liquid species abounds in Trinidad, where it forms a lake said to be three miles in circumference, and where, when mixed with grease or common pitch, it is used for paying the bottoms of ships. It has also been met with in Persia, in Dalmatia, and in the Hartz. The compact variety again, occurs, forming nodules, in the lead mines of Matlock in Derbyshire, at Hurlet near Paisley, in sandstone near Bathgate in Linlithgowshire, imbedded in sandstone in Albania, Hanover, and in many parts of the Continent. The more liquid varieties of this mineral admit of considerable application for illuminating, for fuel, in the manufacture of varnish, &c., besides its common application to pavements.

The bitumen employed by the ancient Babylonians, instead of mortar, to unite the sun-dried bricks in their colossal structures, was evidently the semi-liquid bitumen which we now designate petroleum; and the state in which the mighty ruins still exist shows how imperishable a cement this material afforded. The principal source whence this bitumen was obtained was the fountains of Is, the modern Hit, on the right bank of the Euphrates. These fountains, which are considered as an inexhaustible source of bitumen, still continue to pour it out copiously, mingled with intensely saline sulphureous thermal waters. Much fine salt is now made there by a rude process of spontaneous evaporation; but the bitumen floating on the waters is now only employed to pitch the wicker boats and coracles of the Euphrates and the Tigris. The celebrity of these fountains caused them to be visited by Alexander the Great, by Trajan, and by Julian. The geology of the district presents little peculiarity; the principal rock being an argillaceous limestone, over which in many places lies a coarsely-granular gypsum: but the cause which has for several thousand years produced a perennial distillation of bitumen in this spot, lies probably at a considerable depth below the surface.

BIVALVE, a term in Conchology for a shell which consists of two valves. It is also applied in Botany to a pericarp in which the seed-case opens into two parts.

BIVOUAC (German *beiwacht*), the watch or guard of an army by night during a siege, or in the presence of an enemy. When an army does not regularly encamp, but lies under arms all night, the soldiers passing the night around the

Bizari || Black.

watch-fires, or with such shelter as they can find or construct upon the spot, it is said to *bivouac*.

BIZARI, PIETRO, a poet and historian of the sixteenth century, born near Ancona. Having adopted the doctrines of the Reformation, he took refuge in Scotland, where he was well received by the Regent Murray. (Tiraboschi.)

BIZERTA, or BENZERT, a seaport in the kingdom of Tunis, on a gulf of the same name, which communicates with a lake in the interior. It occupies the site of the ancient Hippo Zaritus, the harbour of which, by means of a spacious pier, protecting it from the north-east wind, was rendered one of the safest and finest on this coast. This important work, however, has been entirely neglected by the Turks, whence the port has been choked up, and now receives only small vessels. The place, however, is still about a mile in circuit, defended by several strong castles and batteries. The principal employment of the inhabitants consists in fishing. The adjoining lake abounds in fish, particularly mullets, the roes of which, dried and formed into the substance called botargo, form a considerable article of Mediterranean commerce. It is situated 38 miles north-west of Tunis. Long. 9. 50. E. Lat. 37. 17. N.

BLABY, a parish and village in Leicestershire, hundred of Guthlaxton. The village, $4\frac{1}{2}$ miles S.W. of Leicester, contains a fine old parish church, a Wesleyan and a Baptist chapel, and a handsome national school. It is near the line of the Midland railway. Pop. of parish in 1851, 1952, chiefly engaged as framework-knitters and glove-makers.

BLACK, Dr JOSEPH, distinguished for his discoveries in chemistry, was born in France, on the banks of the Garonne, in the year 1728. His father was a native of Belfast, but descended from a Scottish family which had been some time settled there. Mr Black, the father, was engaged in the wine trade, and resided chiefly at Bordeaux.

He is represented as a man of extensive information, of candid and liberal sentiments, and of amiable manners; but particularly distinguished by the strength of his attachments, and the warmth of his heart. These estimable qualities procured him the friendship and intimacy of Montesquieu, who was one of the presidents of the court of justice in the province while Mr Black resided at Bordeaux.

Some time before Mr Black retired from business, he sent his son Joseph, then in his twelfth year, to Belfast, to prosecute his studies; and when he had completed the usual course of instruction in a grammar school, he was sent to the university of Glasgow, in the year 1746. During the time he studied at that seminary, his attention seems to have been principally directed to physical science; and he became a favourite pupil of Dr Dick, then professor of natural philosophy. After having completed the ordinary course of general study at the university, he made choice of the profession of medicine; and directed his views to those pursuits and studies which were necessary to qualify him for that profession.

About this time Dr Cullen was appointed to the lectureship of chemistry in the university of Glasgow. Hitherto the science had been treated as a curious, and only in some respects as a useful art. That great man, conscious of his own strength, and taking a wide and comprehensive view, saw the unoccupied field of philosophical chemistry expanded before him. He was satisfied that the science was susceptible of very great improvement by means of liberal inquiry and rational investigation. He was therefore determined to enter the unbeaten path, and to conduct his followers to those unexplored regions which are included in the wide range of this comprehensive and attractive science. While these views were opening in the mind of Dr Cullen, Black became his pupil; and it was perhaps to this fortunate circumstance that he was indebted for the foundation of his future reputation as a philosopher and a chemist. The liberal and extensive views of Cullen happily accorded with the enlarged habits of thought which the young philosopher had previously acquired. Dr Cullen took a deep interest in the progress of his students. He delighted in encouraging and aiding their efforts; and, therefore, perceiving the bias of Black's pursuits, soon attached him to himself. By the intercourse and intimacy which followed, Black was led into the same train of thought, and conducted into the same course of studies; he was received into a closer connection, and became a most valuable assistant in all Dr Cullen's chemical operations. The experiments of Black were frequently adduced to prove facts which were stated in the lecture, and they were considered as unexceptionable authority. Thus commenced a mutual confidence and friendship, which was highly honourable to both, and was never afterwards mentioned by Dr Black but with gratitude and respect.

Black, Dr Joseph.

In the year 1751, Mr Black went to Edinburgh to complete the course of his medical studies. There he resided in the house of his cousin-german, Mr Russell, professor of natural philosophy in that university, a gentleman of enlarged views and liberal sentiments, whose conversation and studies must have been both agreeable and profitable to his young friend.

At this time the mode of action of lithontriptic medicines, but particularly lime-water, in alleviating the pains of stone and gravel, divided the opinions of professors and practitioners. This subject became extremely interesting both to the physician and chemist. And as it is usual for the students to enter warmly into those discussions which give rise to much difference of opinion among their teachers, this subject, being quite suited to his taste, particularly attracted and interested the attention of Mr Black, who was then one of Dr Cullen's most zealous and intelligent pupils. It appears from some of his memorandums, that he at first held the opinion that the causticity of alkalies was owing to the igneous matter which they derived from quicklime. But having prosecuted his experiments on magnesia, this grand secret of nature was laid open to his view, and he was led to conclude that the acrimony of these substances was not owing to their combination with igneous particles; that it formed their peculiar property; and that they lost this property and became mild by combining with a certain portion of air, to which he gave the name of *fixed air*, because it was fixed or became solid in the substances into the composition of which it entered.

This grand discovery, which marks one of the most important eras of chemical science, formed the subject of his inaugural dissertation, published at the time when he was admitted to his medical degree in the university of Edinburgh. He had not availed himself of the time he had studied at Glasgow, but took the whole course prescribed by the rules of the university. This delay, it has been supposed, may have been owing to the investigation of the subject in which he had engaged not having been completed; which determined him to proceed with caution till he had established his doctrine by a train of decisive experiments.

About the time that Dr Black took his medical degree, Dr Cullen was removed to Edinburgh, which created a vacancy in the chemical chair at Glasgow. While he remained at that university, Dr Black had been a diligent and attentive student; and the discovery published in his inaugural essay had added much to his reputation. He was therefore looked up to as a person amply qualified to fill the vacant chair; and accordingly, in the year 1756, he was appointed professor of anatomy and lecturer on chemistry in the university of Glasgow. And it was perhaps fortunate for himself, fortunate for the public and

Black, Dr Joseph.

for science, that a situation so favourable presented itself; a situation which allowed him full time to dedicate his talents to the cultivation of chemistry, which had now become his favourite science.

Along with the lectureship on chemistry, Dr Black's first appointment in the university of Glasgow was to the professorship of anatomy. But the latter branch of medical study was either not so suitable to his taste, or he did not consider himself so well qualified to be useful in it; for, soon after, arrangements were made with the professor of medicine, by which the professors exchanged departments, Dr Black undertaking that of the institutes and practice of medicine.

At this time his lectures on medicine formed his chief occupation; while the perspicuity and simplicity, the caution and moderation, which he discovered in the doctrines which he delivered, gave great satisfaction. The time and attention which were occupied in these lectures, and in the medical practice in some measure necessarily connected with his situation, are supposed by some to have been the principal cause of Dr Black's having suddenly stopped short in that brilliant career on which he had at first so successfully entered. It is more probable, however, that the calm and unambitious temper which seems to have formed a striking feature of his character, and which a less friendly hand than his learned biographer might have set down as nearly allied to indolence, checked the ardour and perseverance which were necessary to excite and carry him forward in the path of research and discovery. Whatever may have been the cause, it is to be regretted that Dr Black, so conspicuous for his patient, judicious, and elegant mode of investigation, and so distinguished for the simplicity, perspicuity, and precision of his reasonings and deductions, should have contributed so little in rearing the noble superstructure of chemical science, the foundation of which he had been the means of establishing on a firm and solid basis.

The theory of the nature of quicklime, and the cause of its causticity, soon became known to the German chemists, and from them it met with strong opposition. Various mysterious doctrines at this time prevailed in the German schools concerning the peculiar nature of fire; and as the notions there entertained of the causticity of alkaline substances involved some of these doctrines, a great many objections were started to a theory which threatened to overthrow long established and favourite opinions. The most formidable opponent of the new theory was Professor Meyer of Osnaburg. All the phenomena of the causticity and mildness of lime and alkali were, according to his explanation, to be accounted for by the action of a substance of a peculiar nature, to which he gave the name of *acidum pingue*. This substance, which was supposed to be formed in the lime during calcination, consisted of an igneous matter in a certain state of combination with other substances. It is a matter of some surprise that Dr Black should have experienced any uneasiness on account of the opposition made to this discovery on mere hypothesis unsupported by facts or even by plausible arguments, when his own doctrine had been fully and irrefragably established by the test of decisive experiment. Nor is it less surprising that, in the course of his lectures for several years, he should have taken great pains in refuting the arguments and in combating the objections of Meyer.

Dr Black's reception at the university of Glasgow was highly flattering and encouraging. As a student he had not only done himself much credit by his successful progress in the different pursuits in which he was engaged, but he had also during his residence there conciliated, in a high degree, the attachment and affection of the professors. When he returned as a professor, he immediately became connected in the strictest friendship with Dr Adam Smith, then professor of moral philosophy in that university; and the friendship thus commenced grew stronger and stronger, and was never interrupted throughout the whole of their lives. A simplicity and sensibility an incorruptible integrity, the strictest delicacy, and singular correctness of manners, marked the character of each of these philosophers, and firmly bound them together in the closest union.

Black, Dr Joseph.

At Glasgow Dr Black soon acquired great reputation as a professor, and became a favourite physician in that large and active city. His engaging countenance, his agreeable and attractive manners, free from all studied endeavours to please, and the kind concern he took in the cases intrusted to his care, made him a most welcome visitor in every family.

It was between the years 1759 and 1763 that he brought to maturity his speculations concerning heat, which had occupied his attention at intervals, from the very first dawn of his philosophical investigations. His discoveries in this department of science were by far the most important of all that he made, and perhaps indeed among the most valuable which appeared during the busy period of the eighteenth century. To enter fully into the nature of his investigations would be improper in this place; but the sum of them all was usually expressed by him in the following propositions.

When a solid body is converted into a fluid, there enters into it and unites with it a quantity of heat, the presence of which is not indicated by the thermometer; and this combination is the cause of the fluidity which the body assumes. On the other hand, when a fluid body is converted into a solid, a quantity of heat separates from it, the presence of which was not formerly indicated by the thermometer; and this separation is the cause of the solid form which the fluid assumes.

When a liquid body is raised to the boiling temperature, by the continued and copious application of heat, its particles suddenly attract to themselves a great quantity of heat; and by this combination their mutual relation is so changed that they no longer attract each other, but are converted into an elastic fluid like air. On the other hand, when these elastic fluids, either by condensation or by the application of cold bodies, are reconverted into liquids, they give out a vast quantity of heat, the presence of which was not formerly indicated by the thermometer.

Thus water, when converted into ice, gives out 140° of heat; ice, when converted into water, absorbs 140° of heat; and water, when converted into steam, absorbs about 1000° of heat, without becoming sensibly hotter than 212°. Philosophers had long been accustomed to consider the thermometer as the surest method of detecting heat in bodies; yet this instrument gives no indication of the 140° of heat which enter into air when it is converted into water, nor of the 1000° which combine with water when it is converted into steam. Dr Black, therefore, said that the heat is concealed (*latet*) in the water and steam; and he briefly expressed this fact by calling the heat in that case *latent heat*.

Dr Black having established this discovery by simple and decisive experiments, drew up an account of the whole investigation, and read it to a literary society which met every Friday in the faculty-room of the college, consisting of the members of the university, and several gentlemen of the city who had a relish for philosophy and literature. This was done on the 23d of April 1762, as appears by the registers. The doctrine in question was immediately applied by its author to the explanation of a vast number of natural phenomena; and in his experi-

Black, Dr Joseph.

mental investigations he was greatly assisted by his two celebrated pupils, Mr Watt and Dr Irvine.

As Dr Black never published an account of his doctrine of latent heat, although he detailed it every year subsequent to 1762 in his lectures, which were frequented by men of science from all parts of Europe, it became known only through that channel; and this gave an opportunity to others to pilfer it from him piece-meal. Dr Crawford's ideas respecting the capacity of bodies for heat were originally derived from Dr Black, who first pointed out the method of investigating that subject.

The investigations of Lavoisier and Laplace concerning heat, published many years after, were obviously borrowed from Dr Black, and indeed consisted in the repetition of the very experiments which he had suggested. Yet these philosophers never mention Dr Black at all; every thing in their dissertation assumes the air of entire originality; and indeed they appear to have been at great pains to prevent the opinions and discoveries of Dr Black from being known among their countrymen. But perhaps the most extraordinary proceeding was that of M. Deluc. This philosopher had expressed his admiration of Dr Black's theory of latent heat, and had offered to become his editor. Dr Black, after much entreaty, at last consented, and the proper information was in consequence communicated to M. Deluc. At last the *Idée sur la Météorologie* of that philosopher appeared, in 1788. But great was the astonishment of Dr Black and his friends when they found the doctrine claimed by Deluc as his own, and an expression of satisfaction at the knowledge which he had acquired of Dr Black's coincidence with him in opinion. M. Deluc has, in his own vindication, published an answer to this charge. See *Edinburgh Review*, No. 12, 1805.

Dr Black continued in the university of Glasgow from 1756 to 1766. In 1766 Dr Cullen was appointed professor of medicine in the university of Edinburgh, and thus a vacancy was produced in the chemical chair of that university. Dr Black was with universal consent appointed his successor; and in the new scene on which he entered his talents became more conspicuously and more extensively useful. But whilst he could not fail to be highly gratified by the great concourse of pupils which the high reputation of the medical school of Edinburgh attracted to his lectures, his mind was forcibly impressed with the importance of his duties as a teacher. This had an effect which, perhaps, was on the whole rather unfortunate. He directed his attention exclusively to his lectures, and his object was to make them so plain as to be on a level with the capacity of the most illiterate of his hearers. The improvement of the science seems to have been altogether abandoned by him. And never did any man succeed more completely. His pupils were not only instructed, but delighted. Many became his pupils merely in order to be pleased; and this contributed greatly to extend the knowledge of chemistry. It became in Edinburgh a fashionable part of the accomplishment of a gentleman.

Perhaps also the delicacy of his constitution precluded him from exertion; the slightest cold, the most trifling approach to repletion, immediately affected his chest, occasioned feverishness, and, if continued for two or three days, brought on a spitting of blood. Nothing restored him but relaxation of thought, and gentle exercise. The sedentary life to which study confined him was manifestly hurtful, and he never allowed himself to indulge in intense thinking, without finding these complaints sensibly increased.

So completely trammelled was he in this respect, that although his friends saw others disingenuous enough to avail themselves of the novelties announced by Dr Black in his lectures, and therefore repeatedly urged him to publish an account of what he had done, this remained unaccomplished to the last. Dr Black often began the task, but was so nice in his notions of the manner in which it should be executed, that the pains he took in forming a plan of the work never failed to affect his health, and oblige him to desist. Indeed he peculiarly disliked appearing as an author. His inaugural dissertation was the work of duty. His *Experiments on Magnesia, Quicklime, and other Alkaline Substances*, was necessary to put what he had indicated in his inaugural dissertations on a proper foundation. His *Observations on the more ready Freezing of Water that has been Boiled*, published in the Philosophical Transactions for 1774, was also called for; and his *Analysis of the Waters of some Boiling Springs in Iceland*, made at the request of his friend T. I. Stanley, Esq. was read to the Royal Society of Edinburgh, and published by the council. And these are the only works of his which appeared in print during his lifetime.

Black, Dr Joseph.

The aspect of Dr Black was comely and interesting. His countenance exhibited that pleasing expression of inward satisfaction, which, by putting the beholder at his ease, almost never fails to please. His manner was wholly unaffected and graceful. He was affable, and readily entered into conversation, whether serious or trivial. He was a stranger to none of the elegant accomplishments of life. He had a fine musical ear, with a voice which obeyed it in the most perfect manner; for he sung, and performed on the flute, with great taste and feeling, and could execute a plain air at sight, which many instrumental performers cannot do. Without having studied drawing, he had acquired considerable power of expression with his pencil, and seemed in this respect to have the talents of an historical painter. Figure indeed of every kind attracted his attention; even a retort, or a crucible, was to his eye an example of beauty or deformity.

He had the strongest claim to the appellation of a man of propriety and correctness. He did every thing in its proper season, and he always seemed to have leisure in store. He loved society, and felt himself beloved in it; and, throughout his whole life, he never lost a friend, except by the stroke of death.

The only apprehension he entertained was that of long-continued sickness, less, perhaps, from any selfish feeling, than from the consideration of the trouble and distress which it would occasion to attending friends; and never was this generous wish more completely gratified. On the 26th of November 1799, and in the seventy-first year of his age, he expired without any convulsion, shock, or stupor, to announce or retard the approach of death. Being at table with his usual fare, some bread, a few prunes, and a measured quantity of milk diluted with water, and having the cup in his hand when the last stroke of the pulse was given, he set it down on his knees, which were joined together, and kept it steady with his hand in the manner of a person perfectly at his ease; and in this attitude he expired without a drop being spilt, or a feature in his countenance changed, as if an experiment had been required to show to his friends the facility with which he departed. His servant opened the door to tell him that some one had left his name; but getting no answer, stepped about half-way towards him, and seeing him sitting in so easy a posture, supporting his basin of milk with one hand, he thought that he had dropt asleep, which sometimes happened after his meals. He went back and shut the door; but before he went down stairs, some anxiety which he could not account for made him return and look again at his master. Even then he was satisfied after coming pretty near, and turned to go away; but returning a second time, and going close up, he found his master a corpse. Sleep, says the poet, is the kinsman of death. Dr Black found the

Black Black-Mail.

relationship very close indeed, and slept (we had almost said *slipt*) away from time to eternity, by a transition so easy as to be imperceptible even to the eye of affection.

BLACK is the negation of colour; or the deprivation of light, resulting from a peculiarity in certain substances, by which they absorb the rays of light instead of reflecting them.

Black, from a remote antiquity, has been regarded as the symbol of mourning and calamity. It is sometimes imposed as a mark of humiliating distinction; the most familiar instance of which is the obligation laid upon the Jews in Turkey of wearing black turbans.

BLACK Act, the statute 9th Geo. I. by which it is felony to appear armed, and with the face blackened or disguised, in any park, warren, &c., for the purpose of hunting or stealing deer, &c.

The *Black Acts* are the Acts of the Scottish parliament during the reigns of the five Jameses, of Mary, and of James VI., down to the year 1586 or 1587; so styled because written in the Saxon character.

BLACK-Bird, Black-Cap, Black-Cock. See ORNITHOLOGY.

BLACK-Book of the Exchequer. See ENGLAND.

BLACK-Books, a name given to those which treat of necromancy. The black-book of the English monasteries was a detail of the enormities practised in religious houses, compiled by order of the visitors under Henry VIII. to blacken them, and thus hasten their dissolution.

BLACK-Forest, a forest of Suabia, in Germany, running from north to south between Ortnau, Brisgau, part of Wirtemburg, and the principality of Furstenburg, towards the source of the Danube as far as the Rhine above Basle. It is part of the ancient Hercynian forest.

BLACK-Friars, a name given to the Dominican order, called also predicants or preaching friars, and in France *jacobins*.

BLACK-guard, a common term for an ill-behaved and disreputable person. It is derived, according to some, from the French *blagueur*; others make it a corruption of *blackard*, black-kind; Dr Johnson simply a compound of "black" and "guard."

BLACK-Lead a name improperly applied to plumbago. Plumbago, or, as it is technically called, graphite, the mineral used in the formation of pencils, crucibles, &c., has no relation to any ore of lead.

BLACK-Letter, a term derived from the dark appearance of the page in books printed or written in the old English or modern Gothic character, which was introduced into England about the middle of the fourteenth century.

BLACK-Mail, a certain rate of money, corn, cattle, or other valuable, anciently paid in the north of England to certain persons who were allied with robbers and plunderers, in order to be by them protected from pillage. This composition with the protectors and supporters of thieves was prohibited by the 43d Elizabeth, cap. 13, and it seems to have been early checked in the English border counties. But in the Highlands of Scotland the exaction of black-mail from the lowland borderers continued in spite of every effort to put it down, till after the Rebellion of 1745.

Black-mail is defined by Dr Jamieson "a tax or contribution paid by heritors or tenants, for the security of their property, to those freebooters who were wont to make inroads on estates, destroying the corns, or driving away the cattle." Rob Roy Macgregor, one of the most noted of these, overawed the country as late as the year 1744, and frequently robbed the Duke of Montrose's factor of the rents after they had been collected from the tenants. Spelman thinks that this illegal imposition received the name of black-mail from the poverty of those who were thus assessed, and as being paid in *black* money, not in silver; and Du Cange adopts this idea with little variation, stating that while brass money is called *blanque* or *blanche maille*, or white money, by the French, the Saxons and English denominate it *black*, in opposition to silver, which they account *white* money. But the more probable opinion is, that the epithet *black* is here used in a moral sense, to indicate the illegality or iniquity of the exaction. Wachter, however, defines "black-mail" *tributum pro redimenda vexa*, deriving it from the German "placken," *vexare, exagitare*, whence "baurenplacker," *rusticorum exagitator*; and Schilter says that "black-en" signifies *prædari*.

Black-Monks ‖ Black Sea.

BLACK-Monks, a denomination given to the Benedictines; in Latin *nigri monachi*, and sometimes *ordo nigrorum*.

Boundaries.

BLACK SEA, or EUXINE SEA, *Pontus Euxinus* of the ancients, is a large inland sea, bounded on the west by Rumelia, Bulgaria, and Bessarabia; on the north by Russian Tartary; on the east by Mingrelia, Circassia, and Georgia; and on the south by Anatolia. It is entered from the Mediterranean through the channel of the Dardanelles, anciently the *Hellespont*, the Sea of Marmora or *Propontis*, and the channel of Constantinople or *Thracian Bosporus*; and it is connected with the Sea of Azof, or *Palus Mæotis*, by the strait between the Crimea and the isle of Taman, anciently the *Cimmerian Bosporus*, and known by the various modern names of the Strait of Kertch, of Yenikale, and of Taman.

Progressive geography.

Till within less than half a century, the extent of the Black Sea, and the position of several of its principal capes, gulfs, and ports, were very imperfectly ascertained. But soon after the commencement of the French Revolution, the National Institute sent M. Beauchamp to examine this sea, and especially its southern shores. In this enterprise he was much impeded by the jealousy of the Turks: nevertheless, he ascertained that Cape Kerempe, *Carambis*, was placed in the charts too far to the south; that the Gulf of Sansoun, *Amisenus Sinus*, was deeper than it is commonly represented; and that Trebizond, the Tarabazan of the Turks, anciently *Trapezus*, was five or six leagues farther to the west than it appeared in the charts. But recent travellers have discovered that even the Parisian charts are inaccurate. According to Dr Clarke, the Isle of Serpents, the Ulan-Adassi of the Turks, the Fidonisi of the modern Greeks, and ancient *Leuce*, lies fifteen minutes, and the port of Odessa twenty-seven minutes, too far towards the north (Clarke's *Travels*, i. 653); and Mr Macgill ascertained, from two observations of his own, compared with those of some captains who had navigated this sea, that in the French charts even Cape Kerempe is set down fifteen miles too far north, whilst Cape Aria or Saritch or Careza, *Kriu-Metopon*, in the Crimea, is placed twenty-two miles too far south. This, of course, makes a difference in the width of the sea at this place of thirty-seven miles. (Macgill's *Travels*, i. 195.)

Extent.

According to the best authorities, which Mr Arrowsmith has followed in his maps of this sea, it lies between 41 and 46½ degrees of north latitude (the bottom of the Bay of Sansoun penetrating nearly to the 40th degree, and Cape Kerempe stretching out nearly to the 42d), and between 28 and 41½ degrees of east longitude from Greenwich. This will give for its extreme breadth, from Cape Baba in Anatolia to Odessa, about 380 miles, and for its extreme length, from the coast of Rumelia to the mouth of the Phasis, 700 miles. The Black Sea, however, may be considered as divided into two parts, by Cape Aria on the south of the Crimea, and Cape Kerempe on the coast of Paphlagonia; the former lying in about 44½, and the latter in about 42 degrees of north latitude. Both these capes being high land, vessels sailing between them can discover the coast on either side. The circumference of the Black Sea is about 3800 miles.

Name.

The first navigators of Greece who ventured into this sea having been repulsed or massacred by some of the fierce tribes inhabiting its coasts, their countrymen gave it the name of *Pontus Axenos*, or "sea unfriendly to strangers." But when the repeated visits of the Greeks had rendered

Black Sea.

these tribes more familiar with strangers, and commercial intercourse had softened down the original ferocity of their character, Grecian colonies were established at different points on the shores of this sea, and the epithet *Axenus* was changed into *Euxinus*, which has the opposite import, and means "friendly to strangers." It derives its modern name either from the dense fogs which frequently cover it, or from the dangers of its navigation arising from these fogs; from the sudden and violent storms to which it is exposed; and from the shallows hitherto unnoticed in any chart.

Former tate.

The opinion of the ancients, that the Black Sea was formerly much more extensive than it is at present, and that it did not originally communicate with the Mediterranean, is adopted by many modern authors of note, particularly by Tournefort, Buffon, Pallas, and Dr Clarke, and seems to be confirmed by several circumstances. Immense strata of limestone, consisting almost entirely of mineralized sea-shells, may be traced from the Black Sea to the northward as far as the 48th degree of latitude, or about a degree and a half beyond the most northerly point of its northern shore; and Pallas, in the third and seventh volumes of his *Travels*, has pointed out traces of its having formerly extended over the whole desert of Astracan and Jaik. The evidences derived from the appearance of the present coast of this sea are still less equivocal in support of the diminution of its waters. Pliny expressly states that *Taurida* or the Crimea was once not only surrounded by the sea, but that the sea covered all that portion of it which is at present champaign country. Now, from the mouths of the Dnieper to those of the Don there are found continuous layers of marine shells; and if we suppose the waters of the Black Sea to be restored only to the level of these layers, the Crimea will again appear as an island. The alluvial nature of more than three-fourths of the soil of Crimea Proper to the north, the numerous salt lakes and marshes and the remains of marine productions of various kinds which are found there, sufficiently confirm the latter part of Pliny's statement.

Bursting of the Thracian Bosporus.

The ancients also believed that the communication between the Black Sea and the Mediterranean, and the consequent diminution of the waters of the former, was effected by the bursting of the Thracian Bosporus at the period of the great deluge which inundated Greece; and this tradition seems to be confirmed by a reference to existing natural phenomena. The cliffs and hills at the mouth of the Bosporus are composed of enormous pebbles, which appear to have undergone the action of fire, and afterwards to have been rounded by long attrition in water. On the point of the European lighthouse there are immense masses of hard and compact lava; and the rock of which the Cyanean Isles consist appears to have been more or less modified by fire, and to have been cemented during the boiling of a volcano. On the Asiatic side of the strait, a little to the eastward of the Anatolian lighthouse, there is also a range of basaltic pillars, exhibiting very regular prismatic forms. From the consideration of all these circumstances, and from comparing events recorded in history with the phenomena of nature, Dr Clarke considers it more than a conjectural position, "that the bursting of the Thracian Bosporus, the deluge mentioned by Diodorus Siculus, and the draining of the waters which once united the Black Sea to the Caspian, and covered the great oriental plain of Tartary, were all the consequences of earthquakes caused by subterranean fires, described as still burning at the time of the passage of the Argonauts, and the effects of which are visible even at this hour." (Vol. i. p. 680.) It is proper to mention, that Olivier does not coincide with other naturalists respecting the former extent of the Black Sea, or the bursting of the Thracian Bosporus. According to the most recent survey, made in 1840 by Mr Xavier Hommaire de Hell, the difference in level between the Black Sea and the Caspian is 34 feet.

Black Sea.

Changes in its coasts.

The northern and western coasts of this sea have undergone, and are still undergoing, considerable changes; but the southern coast, consisting chiefly of calcareous rocks, is nearly in the same state in which it was in the time of the ancients. According to Valerius Flaccus, the gulfs and bays in the northern and western coasts were extremely deep; most of these, however, are now all either entirely filled up or very much contracted. In proof that the Black Sea and the Sea of Azof are still sustaining a diminution of their waters, it may be stated that ships which formerly sailed to Taganrog and the mouths of the Don, are now unable to approach either the one or the other; that the Sea of Azof has become so shallow, that, during certain winds, a passage may be effected by land from Taganrog to Azof through the bed of the sea; and that the isthmus connecting the Cyanean Isles with the Continent, which does not appear to have existed in the time of Strabo, appears to be increasing. On the southern coast of the Black Sea there is, as far as we know, only one instance of a recession of the waters: the channel which formerly divided the village of Amasrah, *Amastris*, is now entirely filled up, and forms a low isthmus.

Currents, winds, and climate.

A rapid current, which generally flows at the rate of a league an hour, the influence of which is felt at the distance of ten miles from land, where it begins to take another direction, sets from the Black Sea into the Bosporus. Sometimes, however, the long continuance of a strong south-westerly wind effectually counteracts this current. The Black Sea, from its particular form, being like a basin, into which many large rivers pour their streams, is full of currents, particularly in summer, when the rivers are increased by the melting of the snows; and when strong winds act against these currents, a high sea is produced. North-east winds prevail from June to August inclusive; but the most prevalent winds at other seasons of the year are from the S. and S.W. The general climate of the Black Sea is cold and humid; the winters are long, and frequently very severe; but the navigation is free of impediment from ice till the beginning of November, and often much later. The quantity of fresh water conveyed into this sea renders it brackish, and liable to freeze with a moderate degree of cold. It is calculated by some authors, particularly Tournefort (ii. 404), and the Abbé Barthélemy (*Voyage d'Anacharse*, tome i. c. 1), that the volume of water it receives is much greater than that which it discharges into the Mediterranean. Dr Clarke, however, is of opinion that the rivers which fall into the Black Sea and the Sea of Azof do not communicate more water than flows through the canal of Constantinople; and hence he concludes, that admitting the effect of evaporation, the level of the Black Sea is insensibly falling.

Rivers.

The Black Sea receives a considerable portion of the fresh waters of Europe, as well as of Asia Minor. The Danube collects the waters of a great part of Germany, Hungary, Bosnia, Servia, Transylvania, Moldavia, Wallachia, and Bulgaria. The Dniester, Bog, Don, and Dnieper, discharge into it those of a part of Russia and Poland. The Phasis collects those of Mingrelia; and the Sangaris, and Kisil-Irmak, or *Halys*, part of those of Anatolia.

Fishes.

In the Black Sea are found the tunny fish, which enters it to spawn; sturgeon, sterlet, porpesse, mackerel, sole, turbot of two kinds, whiting, and roach. Some writers also speak of herrings entering this sea in shoals, but it is probable that they are only large sprats. Their appearance, however, is considered symptomatic of a good sturgeon season. It abounds with a species of sea-worm, four or five inches long, with a head like an arrow, and a body consisting of a whitish mucilage. This worm is very destructive to ships. It does not confine itself to salt-water, and is therefore not the *Teredo navalis* or *terebranes*.

We shall begin our survey of the coasts and ports of this

Black Sea.

sea, at its entrance from the Bosporus, and proceed along its western shores. Off each point of the entrance of the Bosporus from the Black Sea is a group of rocky islets, which retain their ancient name of Cyanean Islands. These have been already described. From the Bosporus to Kara-Kerman, which lies within a few miles of the southern-most branch of the Danube, the coast is lined by the mountainous ridge of the Balkan or *Hæmus*, which terminates at Cape Emeniah, *Hæmi extrema*. The valleys between these mountains form little coves, where vessels are laden with the timber of the Balkan for Constantinople. The forest of Belgrade, which takes its name from a village near Constantinople, extends along the south-western side of the Black Sea for about 100 miles. Incada lies on this coast in 41. 52. north latitude. Pliny and Ptolemy make mention of this town under the name of Thenias; they also call by the same name a promontory which can only be the Cape Kouri of the present day. On the northern side of the harbour there is fair anchorage; it is only exposed to winds from the E. and S.E., and is sufficiently spacious to contain a fleet; but a heavy sea enters it when those winds blow to which it is exposed. Its chief export is charcoal to Constantinople. At the head of the Gulf of Foros, which is bounded on the north by Cape Emeniah, and runs into the land nearly the same distance, is Bourgas, which exports a considerable quantity of wool, iron, corn, butter, cheese, and wine, to Constantinople. The Gulf of Foros, which is four or five leagues wide, contains several roads fit for the largest ships, and affords the only safe anchorage upon the western coast of the Black Sea.

Coasts and ports of Rumelia.

Coast and ports of Bulgaria.

On the coast of Bulgaria is Varna, or Barna, anciently *Odessus*, a Milesian colony, situated at the mouth of a river which forms a large lake called Dewina, and extensive marshes. There is no anchorage whatever between Cape Emeniah and Varna. This town, which derives its modern name from the small river that discharges itself into the sea below its ramparts, anciently *Ziras*, is celebrated for the siege it sustained, and the long and gallant defence it made during the late war between Russia and Turkey. The possession of the place was indispensable to the Russians, in order to insure their communications by sea; but had it not been for the treason of Jussuf Pasha, the second in command, there is no reason to believe they would ever have succeeded in making themselves masters of it. Varna formerly exported provisions to Constantinople. Between Varna and Mangalia (formerly Galatis) is supposed to have been situated Dionysiopolis. The exports of Varna in 1847 amounted to L.600,000. To the north of Mangalia is situated the port of Kustendji, formerly Tomi, celebrated by the exile of Ovid. The position of this town invests it with a high political importance, now that Russia has possessed herself of the mouths of the Danube. No physical impediment exists to prevent the formation of a ship canal from this point to Tchernavoda on the Danube; the distance is only forty miles; and the remains of Trajan's canal still exist. Were this enterprise carried out, it would be attended with results disastrous to the policy of Russia in this direction, but eminently beneficial to the commerce of Europe.

All this coast of Rumelia and Bulgaria, from the Bosporus to the mouths of the Danube, formerly belonged to Thrace.

Kara-Kerman, *Istropolis*, is a large village on the beach, off which lie several shoals that oblige vessels to anchor about a league to the south. Its principal export is corn.

Mouths of the Danube.

From Kara-Kerman to Actiar (Sevastopol), in the Crimea, the coast is very low, nowhere exceeding sixty feet in height, and the shoals formed by the rivers run off to a considerable distance. The Danube discharges itself into the Black Sea between Bulgaria and Bessarabia, by seven mouths, among swampy islands and shifting banks; its stream runs out at the rate of three miles an hour. So great is the extent over which the waters of this river diffuse themselves, from the shallowness of the sea, that at the distance of three leagues from its mouth the water is almost fresh, and within one league it is perfectly fit for use. A very singular appearance takes place near the mouths of the Danube: The porpoise, which everywhere else exhibits a dark colour, is there perfectly white; and hence, as soon as the Greek mariners descry the white porpoise, they have no doubt that they are in the current of the Danube, although in thirty fathoms water, and many leagues distant from its mouth. Opposite the mouths of this river is Serpents Island, already noticed, a barren rock, and remarkable as being the only island in the Black Sea at so great a distance from land. The only building which now exists upon it is a lighthouse; but as the island of Achilles, it had formerly a religious sanctity, and the remains of sacred edifices are still to be found upon it.

Black Sea.

The southern or St George's branch of the Danube belonging to Turkey was formerly the deepest; that, however, silted up, and the traffic of the countries bordering on the Danube was forced through the northern or Kilia branch. In the hands of the Russians it silted up also, and the waters thus turned into the middle or Soulina branch, which became the more available; prior to the treaty of Adrianople the depth of water upon the bar at this mouth of the river was about sixteen feet. There is little more than six feet there now. The bar is formed principally of alluvial deposits, and not of sand washed up by the sea. As, however, it was not stipulated by the treaty of Adrianople upon whom the duty of deepening the channel was to devolve, in the year 1840 Austria entered into a convention with Russia, whereby it was agreed that a tax should be levied by this latter power upon all ships entering the river at Soulina; and in consideration of this privilege Russia became bound to keep the mouth of the river free from all such impediments as now exist. If the Soulina mouth should silt up it is probable that the waters would again force a passage through the Kilia branch, and the Russian fortress of Ismael would command the trade of the Danube. When the Soulina mouth was in the possession of Turkey, every vessel leaving the river was obliged to drag a large rake behind her; this was sufficient to stir up the mud, which was then carried away by the mere force of the current. This practice is prohibited by Russia. Treaty does not allow of forts being built by any power upon the Soulina mouth of the Danube.

Coasts and ports of Cherson.

The Russian province of Cherson is divided from Bessarabia by the Dniester, anciently *Tyras*. A bank before it forms two channels; that on the west being called the channel of Constantinople, and that on the east the channel of Ockzakoff. The one is 150 fathoms broad, and the other eighty fathoms; but neither has more than five feet water. Akerman, on the south bank of this river, has some export trade in corn, wool, wine, wood, hides, and butter. Ancient geographers place upon the right bank of the mouth of the Dniester the town of Hermonactis, and upon the left the tower of Neoptolemus.

Ovidiopol is situated about fifteen miles from the mouth of the Dniester. The Niproffski Leman or Lake is here crossed four or five times a day by a steamer. The traject takes an hour.

To the north of the Dniester extend the interminable steppes; and as far as the mouth of the Dnieper the Black Sea is bordered by a low monotonous line of coast, sometimes argillaceous, but generally calcareous. So gentle is the slope of the vast plains of southern Russia that numerous rivulets on their way to the sea lose themselves in the network of lakes which extends along the shore, and for some distance into the interior. Some of these are lagoons separated from the sea only by sand-banks, and they may

Black Sea. once have served as harbours to Greek mariners. After the destruction of the kingdom of Tartary, the only village upon this coast was Kodjabey, a miserable place, but affording a comparatively safe roadstead. When the produce of the fertile provinces of Poland and New Russia sought an outlet, the huts of Kodjabey were exchanged for the palaces of Odessa.

The population of this city exceeds 100,000. It therefore ranks as the fourth in the empire. It was declared a free port in 1817. It owes its prosperity, not so much to any natural advantages, as to the wise administration of the Duke of Richelieu while he was governor of this province. It is situated close to the coast, which is here very lofty, and much exposed to the winds, especially from the east. In order to render it a safe and commodious port, the duke caused a harbour to be formed, in which ships of no small burden might ride secure from every storm. He also built a large mole, extending half a werst into the sea; with several small ones, and a handsome quay, a werst and a half in length. The roads without the port are safe in summer, and the anchorage is good. Odessa labours under the want of a navigable river, and a great scarcity of fresh water. The total value of the exports for the year 1817 amounted to 38,000,000 paper rubles;[1] since then they have been very fluctuating. In 1818 they fell without any transition to 20,000,000. During the war of 1828–29 they sank to 1,673,000. After the treaty of Adrianople, the exports again rose to 27,000,000. In 1838 they reached 41,000,000, and the imports 20,000,000. The year 1839 was the most memorable in the history of Odessa. The exports consisting almost entirely of corn, amounted to 48,000,000 paper rubles. In 1840 there was a diminution of 7,184,021 rubles; and in 1841 the first quarter alone presented a decrease of 6,891,332 rubles in comparison with the corresponding quarter of 1840. The amount of wheat in 1852 shipped in 203 British vessels, was 453,700 quarters. The amount of Indian corn exported to Great Britain in 1851 in 47 vessels was 74,065 quarters. In 1852, in 101 ships, we received 219,170 quarters of the same article. The principal imports are wine, chiefly French, some rum, raw silk, coffee, sugar, oil, soap, sulphur, fruit, linen cloth, &c., but all in rather limited quantities. The great article of export is wheat, which, however, in the opinion of Mr Macgill, is very far inferior to that of Taganrog, being soft, and apt to heat; besides this, grain, rye, barley, oats, tallow, and tallow candles, bees-wax, iron, hemp, &c., are exported.

The Dnieper, *Borysthenes*, which separates the Russian provinces of Cherson and Taurida, forms, near its mouth, a shallow and marshy lake, two and a half miles broad abreast of Ockzakoff, but more at the confluence of the Bog. The entrance is almost closed by shifting sand-banks, between which there are seldom more than five feet water. The river continues frozen from the middle of December till the middle of February; and in the month of May it overflows its banks, leaving stagnant lagoons in all the low country. The Bog, *Hypanis*, falls into the Gulf of Leman, or estuary of the Dnieper. The small island of Berèzane is situated opposite the mouth of the latter river, almost inaccessible on account of its perpendicular cliffs of rock and clay. Ockzakoff is an inconsiderable port, lying at the junction of these rivers; its harbour is perfectly secure, but the little trade it formerly possessed has been drawn away to Odessa. Ockzakoff was founded at the close of the fifteenth century by Mengli Ghiri Khan of the Crimea, on the ruins of the ancient Alektor, under its Turkish name of Ozou; it was twice taken by the Russians, on the 13th June 1737 under Marshal Munich, and 15th December 1788 under Potempkin. All the Turkish buildings have long since been demolished. Opposite to Ockzakoff is Kinburn, which, before the building of Cherson, was intended by the Russians as their principal depôt for the merchandise sent from the provinces bordering on the Dnieper. The extension of the Russian dominions in the west has caused even Cherson, on the right bank of the Dnieper, to be superseded by Odessa. Yet corn, hemp, and other articles of exportation, are so much cheaper and more plentiful here, that many foreign vessels still prefer this port, though they are obliged first to perform quarantine, and unload their cargoes at Odessa. The Dnieper is five miles wide at Cherson, but only vessels drawing six feet can ascend to it. The Russians, however, have a large arsenal here, and build line-of-battle ships, which are floated down the river on machines, and afterwards conveyed to Ockzakoff to be equipped. Cherson was founded by the Empress Catherine in 1788, and contains a population of about 8000 inhabitants. Between Cherson and Nicolaïef is situated the tomb of Howard the philanthrophist. Nicolaïef, on the Bog, a fine river, without bar or cataract, and with deep, still water, is the station for vessels when built; and here they are laid up to be repaired. It has extensive marine arsenals, and, next to Sevastopol, is one of the most important naval stations on the Black Sea. Black Sea.

The long narrow belt of sand Djarib-Agatch, celebrated as the course of Achilles (Δρόμος Ἀχιλλέως), extends into the shallow Gulf of Kerkinit (Temyraces of Strabo), which divides the peninsula of the Dnieper from that of the Crimea.

Southern coast of the Crimea.

The southern coast of the Crimea is lofty and precipitous; the mountains beginning at Balacklava, *Portus Symbolorum*, and extending to Caffa, *Theodosia*. Some of these are celebrated in antiquity, and are no less remarkable for their formation and appearance. The mountain Tchedirdagh, *Trapezus*, rises abruptly from the coast about Alusta to the height of 4740 feet, according to Messrs Englehardt and Parrot; it exhibits a mass of limestone very compact, of a gray colour, and, according to Pallas, yielding a slightly fetid odour on being rubbed. The most remarkable headland of the Crimea is Cape Tarchanskoi, called by the Tartars Aya Burun, or the Sacred Promontory, probably the *Parthenium* of Strabo; one of the loftiest mountains in the Crimea, terminating abruptly in the sea, and forming the western point of the peninsula. It consists entirely of marble. On the southern point is Cape Saritch, *Kriu-Metopon*, formerly noticed.

Western coast of the Crimea.

The first port of note on the western coast of the Crimea is Kosloff, or Eupatoria, from which, in 1793, 176 vessels were freighted with corn, salt, and leather. It is still the most thriving port in the Crimea, and owes its prosperity to the Karaite Jews, who compose the greater part of the population, which amounts to 10,000. Its exports in 1839 were 2,394,867 rubles. Sevastopol, formerly Actiar, *Ctenus*, is the chief station of the Russian Black Sea fleet, to which indeed it is exclusively appropriated, no merchant ship being allowed to enter it except in distress. The natural advantages of this harbour are very great. The largest vessels may lie within a cable's length of the shore. Here the fleets of the world might ride in security, and have convenient anchorage; and in any of the ports, vessels find from 21 to 70 feet depth of water, and good anchorage. The harbour somewhat resembles that of Malta. The principal branch runs eastward for a distance of four miles and three quarters, and has an average breadth of 1000 yards; it is terminated by the valley of Inkerman, and receives the muddy waters of the Tchernoi Retchka. The southern shore of this roadstead is indented by three deep coves. Upon the high ridge which separates two of these (Artillery Bay from South Bay) the town is situated. The barracks and stores, admiralty buildings, and numerous churches, present an imposing appearance. The streets are broad, the houses handsome, and the population exceeds 40,000.

[1] A paper ruble equals 10½d.

Black Sea.

The northern shore presents a line of cliffs of no interest. South Bay is 3000 yards in length, and sheltered by high limestone cliffs. It is here vessels are rigged and unrigged, and a long range of hulks and pontoons are moored along the shore. Beyond South Bay, and communicating with it, is the creek in which the government docks are situated; they were constructed under the superintendence of Colonel Upton. They are five in number, and placed on two sides of a quadrangular basin. The dock basin is supplied with water by a canal which, passing through a tunnel at Inkerman, joins the Tchernoi Retchka at Tchorgouna. From the quarries at Inkerman has been brought the freestone of which these docks were constructed. They are said to have cost the Russian government 9,000,000 rubles. Careening Bay is still further to the eastward. The entrance to the harbour of Sevastopol is narrow, and defended by four forts, consisting each of three tiers of batteries, and mounting from 200 to 300 pieces of artillery. These are said to be badly constructed, and not so formidable as they look. The waters of the harbour are infested with a worm which seems to have its origin in the Tchernoi Retchka. Between Sevastopol and Cape Chersonese, there are six distinct bays running inland parallel to one another, viz., the Quarantine Bay, the Bay of Sands (Pestchannaia), the Bay of Butts (Strelezkaia), Round Bay (Kruglaia), the Bay of the Cossack (Cozatchaia), and Double Bay (Dvoinaia): all these possess good anchorage, but have not been used since the Heraclean colony of Cherson, the ruins of which still exist, flourished upon the peninsula. Upon turning sharply round Cape Chersonese, the monastery of St George, hanging upon the steep mountain side, comes into view, while an opening so narrow as to be imperceptible until reached is the entrance to the harbour of Balaclava, at the head of which is established a colony of Arnaout Greeks. It is one of the most remarkable ports in the Crimea, appearing from the town land-locked by high precipitous mountains. Its entrance is so extremely narrow, that only one ship can pass at a time; but within the port it is three-quarters of a mile long and 400 yards broad. It is secure from storms in all weather, and ships of war of any size or rate may find in it sufficient depth of water. The mountains which surround it are of red and white marble, and the shore in some parts is covered with gold-coloured mica, in a state of extreme division. This port is closed against the vessels of all nations, not excepting Russians, to prevent smuggling. From Balaclava the coast trends to the S.E. to Cape Saritch (Kriu-Metopon), the only anchorage is at Laspi. Cape Saritch, the southern point of the Crimea, is the commencement of that magnificent chain of limestone cliffs, the existence of which has rendered the southern shore of Taurida so renowned for its beauty. Sheltered from the keen winds of the north, the most luxuriant vegetation clothes those banks of detritus which slope gently from the base of stupendous precipices to the sea. Numerous villas belonging to the Russian aristocracy are picturesquely scattered amid the vineyards and olive groves which descend to the water's edge. Orianda, the chateau of the empress, and the castle of Alupka, the residence of Prince Woronzoff, are the most celebrated of these.

Southern shores of the Crimea.

The modern watering-place of Yalta is situated in a bay to the eastward of Cape Aiotodor. Beyond, Alushta (the Alustan Phrurion of the middle ages), and Soudagh (the Soldaya of the Genoese), are the only places worthy of note; at the latter the limestone range terminates, and the coast, which affords no good harbour after rounding Cape Chersonesus, now forms the magnificent Bay of Caffa, or Theodosia, founded by the Milesians. Caffa was afterwards incorporated into the kingdom of Bosporus. In 1280 it became the splendid metropolis of the Genoese dominion in the Black Sea. In 1475 it surrendered to an Ottoman fleet, under Achmet Pasha, and dwindled down into a Turkish garrison, only to rise to greater glory than ever in the middle of the seventeenth century, when the Turks gave it the name of Koutchouk Samboul (Little Constantinople); it then contained a population exceeding 80,000 souls. It has now sunk to the abject condition of a Russian town,—has been sacrificed to Kertch,—and were it not for the associations connected with it, would be unworthy of notice. The exports of Theodosia in 1839 amounted to 955,108 rubles.

Black Sea.

The harbour of Theodosia, and those upon the south-western shore of the Crimea, are the only harbours in Russia which do not freeze in winter. From the Cape of Schouda, which forms the eastern shore of the Bay of Theodosia, the coast upon which Greek colonies formerly flourished, is now deserted, and the whole peninsula of Kertch is a slightly undulating steppe. The straits at their entrance are about twelve miles broad, with an average depth of three fathoms. Upon rounding the Cape of Akbourum, the town of Kertch (Ponticapeum) rising up the hill of Mithridates bursts upon the view. It contains a population of 10,000 inhabitants, and owes its prosperity entirely to the commerce of the Sea of Azof, which finds its outlet through the Cimmerian Bosporus. Upwards of 1000 vessels passed through these straits in 1851. Seven miles to the north of Kertch stands the dilapidated fortress of Yenikale. The straits are here very narrow; the nearest point of the Asiatic shore is the projecting Cape Kammenoi. The depth of water on the bar of Touzla does not exceed two fathoms. The straits are altogether nearly thirty miles in length, and devoid of any remarkable beauty. They are frozen over in winter.

Coast of Anatolia.

The coast of Anatolia, on the Black Sea, extends to the Kisil-Irmak, which falls into the sea a little to the west of the Gulf of Sansoun. It is lined by high mountains, terminating in lofty promontories, and forming a steep and clean coast, with numerous little coves, into most of which small rivulets fall. The most remarkable headlands are Cape Kili-Mili, east of Erekli; Cape Kerempe, the north point of Asia Minor, very high land with breakers off it; and Cape Indji, a low point to the west of Sinope. The principal rivers on this coast, besides the Kisil-Irmak, *Halys*, and the Sakaria, *Sangarius*, already noticed, are the Falios, *Billæus*, and the Barthin, *Parthenius*. The only port of consequence is Sinope or Sinoub, strongly situated on the narrow and low isthmus of a rocky peninsula. The mole which formed its port is nearly in ruins. The depth of water is twelve feet. There is, however, a good road for the largest ships, and Turkish vessels of war were formerly built here. Sinope is the nearest port on the Black Sea to Angora, the only place hitherto known that supplies the fine goats' hair of commerce.

Coast of Roum;

From the Kisil-Irmac to Vona the coast is named Roum by the Turks. The chief places are Sansoun, *Amisus*, on the Jekyl-Irmak, which falls into the deep Gulf of Sansoun. Imports of Sansoun in 1848, L.207,121; in 1849, L.128,115; in 1850, L.199,925; in 1851, L.193,911. Exports in 1848, L.306,000; in 1849, L.280,355; in 1850, L.209,960; in 1851, L.172,804. Fatsa, *Polemonium*, at the mouth of the Sidemus; Budjah and Vona, *Boona*, on the cape of the same name.

of the Laziens.

From Vona the coast takes the name of the tribes that inhabit it. The Laziens, *Lazi*, occupy the coast from Vona to the Tchourouk. The principal port on this coast is Trebizond, which, although it can admit only small vessels, has nevertheless a considerable trade. One hundred and fifty or two hundred small craft annually sail to Taganrog, with *nardek*, a marmalade of grapes, and *beckmiss*, a syrup made for the use of the distilleries there. In 1848, 132 ships entered the port of Trebizond; of these 39 were British. The total imports amounted to L.1,726,052; of which L.997,666 was British. The total exports L.207,545; of which L.71,296 worth were in British ships. In 1851 only 23 British ships out of 172 entered the port, with cargoes to the value of L.319,479. But these cleared out with L.106,844

Black Sea.

worth of cargoes. The total exports of Trebizond in this year amounted to L.496,708. The Turkish trade with this port has greatly increased within the last few years. The anchorage is not very good. Batoum has recently become a place of some importance as a Turkish garrison; it is situated at the mouth of the Tchourouk (Batys, from whence probably the present name), and overhung by the lofty mountains of Akhaltzik. About twenty miles to the south of the Phasis the little river of Natănèby (Isis of Arrian) falls into the sea, and separates the Turkish from the Russian dominions. Fort St Nicholas upon its right bank is the last Russian outpost. Next to the Laziens, the Gurions occupy the coast as far as the Rioni or *Phasis*. At its mouth this river is sixty fathoms deep and half a league broad, but there is a small island in the midst of its channel. The only port in the country of the Gurions is Poti, to which the merchants of Georgia resort. The Mingrelians occupy the country of the ancient Colchians. Redout Kalè at the mouth of the Khopi, has recently risen into importance since it has become the port of Tiflis, and steamers ply between it and Odessa. At the mouth of the Tugour (Megapomo) is situated the fort of Anaklia. The little province of Zamourzakhan intervenes between Mingrelia and Akbassia, which extends from the Galazkha to the fort of Gagra. The most important places in Akbassia are Iskourias (supposed to be ancient Dioscourias), Soutchoum Kalè, one of the best harbours on the coast, and Pitzounda, celebrated for its church founded by the Emperor Justinian. Between Gagra and Anapa the coast is occupied by the Circassian tribes of the Ardonas, Saghis, Oubikhs, and Chapsoukes. The port of Guelendchik is the best upon the Circassian coast, which is here overhung by the towering range of the Caucasus. At Anapa the mountains cease, and a little distance to the west one arm of the Kouban falls into a lagoon connected with the sea by a narrow channel called Boughaze, upon which there is never more than five feet of water. Another arm, the Kara Kouban, falls into the Sea of Azof; it is not navigable. The Kouban was the former boundary of the empire in this direction. The Asiatic shore of the straits of Kertch is low, and Taman is situated at its most western extremity. The Gulf of Taman is about thirty miles long.

Coast of the Gurions.

The Kuban.

Commerce of the Black Sea.

The Phœnicians, and after them the Egyptians, in ancient times possessed the commerce of the Black Sea. It passed to the Greeks at the commencement of the seventh century B.C. The Milesians and Heracleans then laid the foundations of the two states of Bosporus and Cherson.

The commerce of the Greek colonies, which were at first simple factories, found speedy development as the productions of civilization were exchanged for the raw material furnished by the neighbouring tribes. Numerous towns were founded upon the shores of Taurida, and the relations of the mother country became more intimate as the wealth and importance of these latter increased, until at last Athens became in a great measure dependent upon Taurida for her cereal supplies; and Strabo gives an account of a large exportation of corn made to the Athenians by Leucon king of Bosporus (book vii. chap. 5).

After the Greeks the Romans penetrated in their turn into the Black Sea. Under their dominion the Pontus Euxinus was less frequented. Rome, mistress of the entire world, attracted to herself alone all commercial relations, and the shores of Taurida, too far from the capital, and less favoured than the provinces in Africa, were insensibly abandoned.

About the third century after Christ, the empire of the East was founded and Constantinople built upon the shore of the Thracian Bosporus, and trade upon the Black Sea received a new impetus under the auspices of the Byzantine Emperors.

But the thirteenth century formed the most remarkable epoch in the commercial history of the Black Sea. Guided by their ambition and mercantile instinct, the Genoese landed upon the coast of Taurida, and in 1280 founded the brilliant colony of Caffa. Factories were established at Tana on the mouth of the Don, in Colchis, and on the Caucasian coast, and even the imperial town of Trebizond was forced to admit one of the most important factories of the republic. The Genoese colonies thus became the general emporium of the rich productions of Russia, Asia Minor, Persia, and the Indies. They monopolized for more than two centuries all the traffic between Europe and Asia, and presented a marvellous spectacle of thriving greatness. All this glory had an end. By the capture of Constantinople in 1453 this commerce was nearly destroyed; and by the capture of Caffa in 1476 it was completely annihilated. The Venetians, who had obtained from the Turks the right of navigating the Black Sea in consideration of a yearly tribute of 10,000 ducats, strove in vain to take the place their rivals had lost. They were expelled in their turn from the Black Sea, and the Dardanelles were closed against all the nations of the West; and the Turks, and their subjects the Greeks of the Archipelago, alone possessed the privilege of passing through the strait. To obtain a share of the commerce thus restricted to Mussulman subjects was a favourite project with Peter the Great. In 1699 he succeeded in subduing Azof and the country round it; but by the unfortunate battle of Pruth, in 1711, he was compelled to relinquish his conquests. His successors, however, especially Catherine II., aimed at the same object. This enterprising sovereign, by the treaty of Kaïnardgy in 1774, and afterwards by the treaty of Jassy in 1791, completely accomplished her object; the Turks being obliged to surrender a part of Lesser Tartary and the Crimea, to allow the Russians to establish a navy in the Black Sea, and to permit their flag a free passage through the Dardanelles. In 1784 the Porte granted the privilege of navigating the Black Sea to the Austrians. But no other European nation obtained this privilege, although the French carried on a considerable trade under the Russian and Imperial flags, till after the conquest of Egypt by the French, when a treaty was concluded between the French government and the Porte, by which the latter granted to the former the free navigation of this sea. At the peace of Amiens the navigation was opened to the Prussian, Spanish, Neapolitan, Dutch, Ragusan, and English merchant flags; and all these nations were allowed to have resident consuls in the Turkish ports of this sea. The English, however, by secret treaties with the Turks, in the reign of James I. and Charles I., had been allowed to navigate this sea; and in 1799 this privilege was renewed.

Black Sea.

Russian statistical reports are so little to be relied upon that it is difficult to give any very accurate returns of the general trade of the Black Sea. Within the last twenty years a total change has been effected in the aspect of its commerce. This is chiefly to be attributed to the existence of the British market. When importations of corn into England were freed from fiscal influences, the vast and fertile plains of southern Russia, and the rich valley of the Danube, supplied the ever increasing demand; and the requirements of Great Britain, however they may increase, will be met by enormously elastic powers of production. The prohibitive policy of Russia exercises however a most injurious influence upon foreign trade, and combines to render the expense of freight upon the coasts of the Black Sea higher than upon any other eastern sea-board. In consequence of the more liberal commercial policy of Turkey and the Danubian principalities the exports of Rumelia, Moldavia, and Wallachia, are increasing far more rapidly than those of the Russian provinces, while the grain is more highly esteemed in the English market. The total amount of wheat received by Great Britain in 1852 from the Russian shores of the Black Sea was 789·750 quarters in 374 vessels. The total

Black Sea ‖ Black-Whytlof.

amount shipped from Rumelia and the Danubian principalities was 112·650 quarters, in 92 vessels. The general exports of the principalities have been gradually increasing. In 1849 the total value of the imports amounted to L.809,240; in 1850, L.898,715; and in 1851, L.896,895. The total value of the exports in 1849 was L.1,113,272; in 1850 it was L.839,712; and in 1851, L.1,274,525. As the corn trade to the British dominions is the mainly important branch of commerce in the Black Sea, those statistics connected with it which are derived from the English official reports contain all that is most important. Apart from this no very remarkable features in the local trade have been recently developed, nor, if there were, are there any authentic reports of its extent.

Principal articles of commerce.

The principal articles of commerce afforded by the countries on the Black Sea are wheat, rice, tobacco, hides, tallow, hare-skins, honey, wax, iron, and yellow grains for dyeing from Rumelia and Bulgaria, by the ports of Varna and Bourgas. The same articles, with the addition of wool, butter, hemp, masts, ship-timber, and pitch, are exported from Moldavia and Wallachia, by Ibraila and Galatz on the Danube. From Bessarabia by Ovidopol, and from the province of Cherson by Odessa, Akermann, and Cherson, come corn, oak-timber, hides, tallow, tar, shagreen, wax, honey, hemp, sail-cloth, and wool;—from the Crimea by the ports of Actiar, Kosloff, and Caffa, corn, wool, wax, honey, dried and salted hides, deer-skins, morocco leather, sheep-skins, salted and dried fish, potash, felt, caviar, wine, silk, and saltpetre;—from the countries on the Sea of Azof by the ports of Taganrog, Berdianski, and Mariapol, iron (of which Constantinople and Smyrna require about 60,000 quintals each), dried fish, caviar, butter, hides, tallow, wheat, timber, furs, sail-cloth, cordage, hemp, linens, wax, and wool;—from Anatolia by the ports of Erekli, Amasreh, Ineboli, Sinope, and Uniah, hides, dried fruits, linens, linen thread, wax, honey, hemp, copper, and ship-timber;—from the coast of Roum and Sansoun, the same articles;—from the countries of the Laziens and Gurions, principally by Trebizond, all the above articles except ship-timber;—and from Mingrelia, and the country of the Abasses, principally by Soudjuk and Anapa, slaves, timber, box-wood, wool, silk, furs, butter, hides, wax, and honey. The trade to those coasts is entirely carried on by a few Greeks of Constantinople, and is very insignificant.

The Russian fleet in the Black Sea consisted in 1853, according to M. de Haxthausen, of 18 ships of the line, 12 frigates, and 10 corvettes, brigs, &c., exclusive of steamers.

See Clarke's *Travels*, vol. i. 4to edition; Macgill's *Travels in Turkey*, &c. vol. i.; Coxe's *Travels*, vol. iii. 8vo edition; *Essai Historique sur le Commerce et la Navigation de la Mer Noire*, par le Baron de Saint Joseph, Paris, 1820; Rottier, *Itinéraire de Tiflis à Constantinople*, 1829; Alexander's *Travels in the East through Russia and the Crimea in* 1829; Oliphant's *Russian Shores of the Black Sea*, 1853. (W. S—N.) (L. O.)

Black-Tin, tin-ore when dressed, stamped, washed, and ready for smelting. It is the ore comminuted by beating into a black powder, like fine sand.

Black-Wadd, an ore of manganese, of which, according to Klaproth, it contains 68 per cent. It is of a brown or black colour, opaque, sectile, and soils the fingers. Though its specific gravity is as high as 3·706, it appears very light in the hand, but imbibes water with violence, and immediately sinks when immersed. Mixed with linseed oil it inflames spontaneously. The localities of black-wadd are particularly Devonshire and Cornwall. The dendritic delineations, often so beautiful upon limestone, steatite, and other substances, are supposed to derive their colouring matter from this mineral. It is used as a drying ingredient in paints.

Black-Whytlof, in our old writers, bread of a middle fineness between white and brown, called in some parts "ravel-bread." In religious houses it was used as a common sort; the *panis conventualis* being pure manchet, or white bread.

Blackall ‖ Blackburn.

BLACKALL, Offspring, an eminent English prelate, born at London in 1654, and educated at Catharine-Hall, Cambridge. For two years he refused to take the oath of allegiance to William and Mary, but at last submitted, though he seemed to condemn the principles of the Revolution. In a sermon preached before the House of Commons 30th January 1699, he animadverted on Toland's assertion, in his life of Milton, that Charles I. was not the writer of the *Icon Basiliké;* and also on some insinuations against the authenticity of the Holy Scriptures; which produced a controversy between him and that author. In 1700 he was chosen Boyle's lecturer; and in 1707 was consecrated bishop of Exeter. He died at Exeter in 1716, and was interred in the cathedral. His works were published in two vols. folio, 1723.

BLACKBURN, a parish, township, market-town, and since the Reform act a parliamentary borough, is situated on a brook, called in Domesday book "Blackeburn," but now only known as "The Brook," in the hundred of Blackburn, in the northern division of the county of Lancaster, 209 miles from London by railway, 35¾ from Preston, and 21 miles N.N.W. from Manchester. The parish contains 15 townships and 8 chapelries, and is nearly 14 miles long and 10 broad. The living is a vicarage in the gift of the Archbishop of Canterbury, the rector. Its income is marked in the clergy list at L.893, the amount rendered some years back; but as this resulted partly from glebe-lands, which are being yearly let at high rates on building leases, the present value must be far greater. The vicar has 19 livings in his gift, most of them small in money value, though many have large and important populations. The parish church is a very handsome edifice. Almost every form of dissent is here represented, but the Independents are by far the most numerous and influential. There are very many Sunday-schools; but, from the nature of the trade of the town, education is on a rather low scale. Thus, of the 1584 persons married last year (1853) a very small proportion wrote their names. There is a free grammar-school founded by Queen Elizabeth, with a good house but small endowment: it has had no pupils for several years past. There are also a female charity school, several elementary and Sunday schools, a mechanics' institute, a large subscription library, and a small theatre.

Blackburn received a charter of incorporation in the year 1851, when W. H. Hornby, Esq., one of the largest cotton-manufacturers of the place, was elected the first mayor. It returns two members to parliament.

Blackburn is entirely dependent on the cotton trade, and by the industry and skill of its manufacturers, has made wonderful progress during the last few years. By the census of 1801 the population was 11,980; and in 1851 it had increased to 46,536. Several very important inventions have orginated from the firms of Hornby and Kenworthy, and Harrison and Son, by which the trade of Blackburn has assumed a high character in the cotton districts. The names of Peel and Hargrave are identified with the place, as belonging to men who in the last century gave an impetus to manufactures. The Leeds and Liverpool canal passes the town; which is also connected by railways with Burnley, Preston, Liverpool, Bolton, and Manchester.

Blackburn, as a town, is in a state of transition, which, unless untoward events interfere, will in a few years give it an entirely new and improved character. Its old, narrow, and irregular streets are giving way to the hand of improvement, and a new town of considerable architectural pretensions is fast springing up. Under an act of parliament the improvement commissioners are widening the streets, and laying out new ones; and a town-hall and exchange is in the course of erection, on a scale of considerable magnificence. An extensive market-house has been recently erected,

Blacking || Blacklock.

with slaughter-houses adjoining. If with these measures of public utility, means go hand in hand to elevate the operatives, Blackburn may one day become equal to any town in Lancashire.

BLACKING, any factitious black, as lamp-black, shoe-black, and the like. A mixture of ivory or lamp-black with linseed-oil makes the common oil blacking. For a shining blacking, small-beer or water is used instead of oil, in the proportion of a pint to an ounce of ivory-black, with the addition of half an ounce of sugar, and as much gum-arabic. The white of an egg substituted for the gum increases the lustre, but is supposed to render the leather liable to crack. A good blacking is prepared by mixing, in certain proportions, ivory-black, sour beer or porter, Florence oil, molasses, and a small quantity of sulphate of iron.

BLACKLOCK, Thomas, a Scottish poet and divine, was born of humble but respectable parents at Annan, in Dumfriesshire, in 1721. When not quite six months old he lost his sight by the smallpox. Under this misfortune, his father and friends endeavoured to amuse him as he grew up by reading to him various books; among others, the works of Milton, Spenser, Prior, Pope, and Addison. His kind and gentle disposition gained the hearts of his companions, who were very assiduous in their good offices, particularly in reading to instruct and amuse him.

Blacklock, at the age of nineteen, had the misfortune to lose his excellent father, who was killed by the fall of a malt-kiln belonging to his son-in-law. Thus suddenly deprived of that support on which his youth had leaned, destitute of almost every resource which industry affords to those who have the blessing of sight, with a body naturally feeble and delicate, and with a mind peculiarly susceptible, this bereavement was doubly severe.

He lived with his mother for about a year after this event, and began to be distinguished as a young man of genius. To poetry he was devoted from his earliest days; and about this time several of his productions were handed about, which considerably enlarged the circle of his friends and acquaintance. Some of his compositions having been shown to Dr Stevenson, an eminent physician of Edinburgh, that gentleman formed the benevolent design of giving him the benefits of a classical education. Blacklock, in consequence, was enrolled a student of divinity in the University of Edinburgh in 1741, and continued his studies under the patronage of Dr Stevenson till 1745, when he retired to Dumfries, and resided in the house of his married sister during the whole time of the civil war which then agitated the country. When peace had been restored, he returned to the university, and pursued his studies for six years longer. During this residence in Edinburgh, he made the acquaintance of several literary men, particularly Mr Hume, who was particularly useful to him in the publication by subscription of the 4to edition of his poems in 1756. Two editions in 8vo had previously been published at Edinburgh in 1746 and in 1754.

After applying closely for a considerable time to the study of theology, in 1759 he passed the usual trials in the presbytery of Dumfries, and was licensed as a preacher, in which capacity he obtained high reputation.

In 1762 he married Miss Sarah Johnston, the daughter of a surgeon in Dumfries; a connection which formed the great solace and blessing of his future life. A few days after this event, he was ordained minister of the church of Kirkcudbright, by presentation from the crown, through the interest of the Earl of Selkirk. This appointment, however, was so violently opposed by the parishioners, that, after a legal dispute of nearly two years, he resigned his right to the living, and accepted a moderate annuity in its stead. With this slender provision he removed to Edinburgh, where he received into his house as boarders a certain number of young gentlemen, whose studies he superintended. Finding that his advancing age and feeble health required quiet and repose, in 1787 he abandoned the tuition of youth. In 1767 the degree of doctor in divinity was conferred on him by the University and Marischal College of Aberdeen.

Blackmore || Blackstone.

In the summer of 1791 he was seized with a slight feverish disorder, which a frame so little robust proved unable to resist; and after about a week's illness it carried him off on the 7th of July.

His writings consist chiefly of poems, of which a 4to edition was published in 1793; to which was added an *Essay on the Education of the Blind*, translated from the French of M. Haüy.

BLACKMORE, Sir Richard, a physician, and voluminous writer of theological, poetical, and physical works, was born in Wiltshire. Having early declared in favour of the Revolution, King William, in 1697, chose him one of his physicians in ordinary, and conferred on him the honour of knighthood. On Queen Anne's accession, Sir Richard was also appointed one of her physicians, which office he held for some time. Dryden and Pope treated the poetical performances of Blackmore with great contempt; and in a note in the *Dunciad* we are informed that his "indefatigable muse produced no less than six epic poems: *Prince and King Arthur*, in twenty books; *Eliza*, in ten; *Alfred*, in twelve; *The Redeemer*, in six; besides *Job*, in folio; the whole book of *Psalms; The Creation*, in seven books; the *Nature of Man*, in three books; and many more." But notwithstanding that Blackmore was greatly ridiculed by the wits, he is not without merit; and Addison, in the *Spectator*, has bestowed some liberal commendations on his *Creation*. It must be mentioned to his honour that he was a moral writer, and a warm advocate for virtue, at a time when an almost universal degeneracy prevailed. He died on the 9th October 1729.

BLACKSTONE, Sir William, an eminent English lawyer, was born at London, July 10. 1723. His father, Mr Charles Blackstone, a silkman, citizen, and bowyer of London, died some months before the birth of our author, who was the youngest of four children; and his mother also died before he was twelve years old. Even from his birth, the care both of his education and fortune was kindly undertaken by his maternal uncle Thomas Bigg, an eminent surgeon in London, who on the death of his elder brothers succeeded to the family estate at Chilton Foliot in Wiltshire. When about seven years old, young Blackstone was put to school at the Charter-house; and in 1735 he was admitted upon the foundation there by the nomination of Sir Robert Walpole, on the recommendation of Charles Wither of Hall in Hampshire, Esq., his cousin by the mother's side. In this excellent seminary his talents and industry rendered him the favourite of his masters, who encouraged and assisted him to the utmost of their power; so that at the age of fifteen he was at the head of the school, and qualified to be removed to the university. He was accordingly entered a commoner at Pembroke College, Oxford, on the 30th of November 1738. At this time he was elected to one of the Charter-house exhibitions, to commence from the Michaelmas preceding, but was permitted to continue a scholar there till after the 12th of December, when he delivered the usual anniversary oration, by which he acquired very great credit. About this time also he obtained Mr Benson's gold prize-medal of Milton, for verses on that poet. In the February following the society of Pembroke College unanimously elected him to one of Lady Holford's exhibitions for Charter-house scholars in that house. Here he prosecuted his studies with unremitting ardour; and although the classics, and particularly the Greek and Roman poets, were his favourites, they did not entirely engross his attention; for logic, mathematics, and the other sciences, were not neglected. At the early age of twenty he compiled a treatise entitled *Elements of Architecture*, intended for his own use

Blackstone. only and not for publication, but esteemed by those who have perused it as in no respect unworthy of his maturer judgment and more practised pen.

Having made choice of the profession of the law, he was entered in the Middle Temple, November 20. 1741. He now found it necessary to quit the more amusing pursuits of his youth for the severer studies to which he had dedicated himself, and betook himself seriously to reading law. He expressed his disagreeable sensations on this occasion in a copy of verses, afterwards published by Dodsley in the fourth volume of his Miscellanies, entitled *The Lawyer's Farewell to his Muse;* in which the struggle of his mind is expressed so strongly, so naturally, and with such elegance of language and harmony of versification, as must convince every reader that his passion for the muses was too deeply rooted to be laid aside without much reluctance, and that if he had pursued that flowery path he might have taken a very respectable place among English poets. Besides this, several fugitive pieces were at times communicated by him to his friends; and he left, but not with a view to publication, a small collection of juvenile pieces, consisting of both original poems and translations. Some notes on Shakspeare, which just before his death he communicated to Mr Steevens, and which were inserted by him in his last edition of that author, show how well he understood the meaning and relished the beauties of his favourite English poet.

In November 1743 he was elected into the society of All-Souls College. In the November following he spoke the anniversary speech in commemoration of Archbishop Chichelay, the founder, and the other benefactors to that house of learning, and was at the same time admitted actual fellow. From this period he divided his time between the university and the Temple, where he took chambers in order to attend the courts. In the former he pursued his academical studies, and on the 12th of June 1745 took the degree of bachelor of civil law; in the latter he applied himself closely to his profession, both in the hall and in his private studies; and on the 28th of November 1746 he was called to the bar. Though but little known or distinguished in Westminster Hall, he was actively employed, during his occasional residences at the university, in attending to its interests, and in mingling with and improving its interior concerns. In May 1749, as a small reward for his services, and to give him further opportunities of advancing the interests of the college, Blackstone was appointed steward of its manors. In the same year, on the resignation of his uncle, Seymour Richmond, Esq., he was elected recorder of the borough of Wallingford in Berkshire, and received the king's approbation on the 30th of May. On the 26th of April 1750 he commenced doctor of civil law, and thereby became a member of the convocation, which enabled him to extend his views beyond the narrow circle of his own society, to the benefit of the university at large. In the summer of 1753 he took the resolution of wholly retiring to his fellowship and an academical life, still continuing the practice of his profession as a provincial counsel.

His lectures on the laws of England appear to have been an early and favourite idea; for in the Michaelmas term immediately after he quitted Westminster Hall, he entered on the duty of reading them at Oxford; and we are told by the author of his Life, that even at their commencement, the high expectations formed from the acknowledged abilities of the lecturer attracted to these lectures a very crowded class of young men of the first families, characters, and hopes. But it was not till the year 1758 that the lectures in the form they now bear were read in the university. Mr Viner having by his will left not only the copyright of his abridgment, but other property to a considerable amount, to the University of Oxford, in order to found a professorship, fellowships, and scholarships of common law, Blackstone was on the 20th of October 1758 unanimously elected Vinerian professor; and on the 25th of the same month he read his first introductory lecture, which he published at the request of the vice-chancellor and heads of houses, and afterwards prefixed to the first volume of his celebrated *Commentaries*. It is doubtful whether the *Commentaries* were originally intended for the press; but many imperfect and incorrect copies having got abroad, and a pirated edition of them being either published or preparing for publication in Ireland, the learned lecturer thought proper to print a correct edition himself, and in November 1765 published the first volume, under the title of *Commentaries on the Laws of England*. The remaining parts of this admirable work were given to the world in the course of the four succeeding years. It ought to be remarked, that before this period the reputation which his lectures had deservedly acquired for him had induced him to resume his practice in Westminster Hall; and, contrary to the general order of the profession, he who had quitted the bar for an academic life was sent back from the college to the bar with a considerable increase of business. He was likewise elected into parliament, first for Hindon, and afterwards for Westbury in Wilts; but in neither of these departments did he equal the expectations which his writings had raised. The part he took in the Middlesex election drew upon him the attacks of some persons of ability in the senate, and likewise a severe animadversion from the caustic pen of *Junius*. This circumstance probably strengthened the aversion he professed to parliamentary attendance; "where," he said, "amidst the rage of contending parties, a man of moderation must expect to meet with no quarter from any side." When, on the resignation of Mr Dunning in 1770, he was offered the place of solicitor-general, he refused that office; but shortly afterwards, on the promotion of Sir Joseph Yates to a seat in the court of Common Pleas, he accepted a seat on the bench, and by the death of Sir Joseph succeeded him there also. This eminent and excellent man died on the 14th of February 1780, in the fifty-seventh year of his age.

Blackwall ‖ Blackwell.

BLACKWALL, Anthony, A.M., a learned author, who, after completing his academical education at Emanuel College, Cambridge, was appointed head master of the free school at Derby, and rector of All-Hallows there. In 1722 he was appointed head master of the free school at Market-Bosworth in Leicestershire; and in 1725 he published the first volume of his most celebrated work, *The Sacred Classics Defended and Illustrated*, of which the second volume appeared shortly after his death. He was presented to the rectory of Clapham in 1726, by his former pupil Sir H. Atkins, as a mark of his gratitude and esteem. It is related that when Blackwall waited upon the bishop of the diocese he was somewhat pertly questioned by a young chaplain as to the extent of his learning. "Boy," replied the indignant veteran, "I have forgot more than ever you knew." He resigned his living in 1729, and returned to Bosworth, where he died April 8. 1730, aged fifty-six. His other works are, an edition of *Theognis*, 1706; an *Introduction to the Classics*, 1718; and a *Latin Grammar*.

BLACKWELL, Thomas, a Scottish writer, born in 1701 at Aberdeen, where his father was a minister. He studied Greek and philosophy in the Marischal College, and took the degree of A.M. in 1718. Being distinguished for uncommon parts and an early proficiency in letters, he was, in December 1723, made professor of Greek in Marischal College, and continued to teach that language with applause till his death. In 1735 he published anonymously at London, *An Inquiry into the Life and Writings of Homer*, 8vo, a second edition of which appeared in 1736; and not long after he published *Proofs of the Inquiry into Homer's Life and Writings*, being a translation of the Greek, Latin, Spanish, Italian, and French notes, subjoined to the original work. In 1748 he published *Letters concerning Mythology*, 8vo, but without his name. The same year he was made principal of Marischal College in Aberdeen; being the only

Blackwell ‖ Bladum.

layman who had been appointed to that office since the patronage came to the crown by the forfeiture of the Marischal family in 1716. In 1752 he became LL.D.; and the year following published the first volume of his *Memoirs of the Court of Augustus*, 4to. The second volume appeared in 1755; and the third, which was posthumous and left incomplete by the author, was prepared for the press by John Mills, Esq., and published in 1764. At the same time a third edition of the two former volumes appeared, which is a proof that his literary talents found many admirers; although it must be acknowledged that the parade with which it is written, and the peculiarity of its language, exposed it, not without reason, to some severity of censure. He died at Edinburgh, March 8. 1758, of a consumptive disorder, which was probably accelerated by his excessive abstemiousness.

BLACKWELL, *Alexander*, son of a dealer in knit-hose at Aberdeen, where he received a liberal education. He studied physic under Boerhaave at Leyden, took the degree of doctor of physic, and acquired a proficiency in the modern languages. He married the daughter of a gentleman in the neighbourhood; and, after an attempt to establish himself as a practitioner in Scotland, he went to London, where he met with no better success. He then became a corrector of the press, and at length set up a printing establishment of his own, which was carried on till 1734, when he became bankrupt. He appears to have subsisted for a considerable time after this event by the ingenuity of his wife, who published "*A Curious Herbal*, containing 500 cuts of the most useful Plants which are now used in the Practice of Physic, engraved on folio Copperplates after Drawings taken from the Life, by Elizabeth Blackwell; to which is added a short Description of the Plants, and their common Uses in Physic, 1739," 2 vols. folio. About the year 1740 Blackwell went to Sweden, and, renewing his intimacy with a nobleman whom he had met at the Hague, resumed the medical profession. Having laid before his Swedish Majesty a scheme for draining the fens and marshes, considerable sums were expended for that purpose under the doctor's direction. Being suspected, however, of being concerned in a plot for changing the succession to the Swedish throne, he was put to the torture; and this not producing the desired confession, he was beheaded, August 9. 1748. Soon afterwards appeared "A Genuine Copy of a Letter from a merchant in Stockholm to his correspondent in London, containing an impartial Account of Doctor Alexander Blackwell, his Plot, Trial, Character, and Behaviour, both under Examination and at the Place of Execution; together with a Copy of a Paper delivered to a Friend upon the Scaffold." Blackwell possessed good natural genius, but was flighty and conceited. His conversation, however, was facetious and agreeable; and he was allowed to have been a well-bred and accomplished gentleman.

BLADDER, a thin membranous bag in animals, which serves as the receptacle of some secreted fluid; as the urinary bladder, the gall bladder, &c. The air bladder of fishes is supposed to assist respiration and to give buoyancy in swimming.

BLADE, the cutting part of an instrument, as of a knife or sword. The sword-blades of Damascus are very celebrated, and bear a high price.

BLADEN, MARTIN, a translator and dramatic author, was originally an officer in the army, and bore the commission of lieutenant-colonel in Queen Anne's reign, under the Duke of Marlborough, to whom he dedicated his translation of Cæsar's Commentaries. In 1714 he was made one of the lords commissioners of trade and plantations, with a salary of L.1000 a-year, which he enjoyed till his death in May 1746.

BLADUM, in the middle ages, a name for all sorts of standing corn; also written *blatum*, *blava*, and *blavium*. In old charters *bladum* included the whole product of the ground, as fruit, corn, flax, grass; and it was sometimes applied to any kind of grain threshed on the floor.

Blaeu ‖ Blair.

BLAEU, or BLAUW, WILLIAM, a learned printer of Amsterdam, and a disciple and friend of Tycho Brahe. His Atlas, Treatises of the Globes, Astronomical Institutions, and other works, together with his fine impressions, have secured his name from oblivion. He died in 1638.

BLAGRAVE, JOHN, an eminent mathematician, was the second son of John Blagrave of Bulmarsh-court, near Sunning in Berkshire. He was sent to St John's College, Oxford, where he applied himself chiefly to the mathematics; and afterwards retired to Southcote-lodge, near Reading, where he spent the remainder of his life. He died in 1611, and was buried in the church of St Lawrence, where a sumptuous monument was erected to his memory. He is said to have been eminently distinguished for his benevolence, candour, and generosity. His published works are, 1. *A Mathematical Jewel*, Lond. 1585, folio; 2. *Of the Making and Use of the Familiar Staff*, Lond. 1590, 4to; 3. *Astrolabium Uranicum Generale*, Lond. 1596, 4to; 4. *The Art of Dialling*, Lond. 1609, 4to.

BLAINVILLE, HENRI-MARIE DUCROTAY DE, a distinguished naturalist, was born at Arques, near Dieppe, Sept. 12. 1777. About the year 1795 he entered the school of design at Rouen, but after a very short time he went to Paris, where he became a pupil of Vincent the painter. Attracted by the lectures of Cuvier and other eminent professors in the College of France, he commenced the study of Anatomy, and in August 1808 he took the degree of M.D.

He now devoted himself to the study of natural history, more particularly the department of myology, and he soon attracted the attention of Cuvier, who requested Blainville's co-operation in a work on comparative anatomy on which he was then engaged. He was also chosen by that illustrious professor to supply his place at the College of France and at the Athenæum, and he soon afterwards obtained the vacant chair of anatomy and zoology in the Faculty of Sciences at Paris. On that occasion he produced his thesis upon that curious animal the ornithorhyncus, or duck-bill.

Blainville's somewhat irascible disposition was probably one cause of the subsequent estrangement between him and Cuvier, which ended in an open and irreconcilable enmity. In 1825 Blainville was admitted a member of the Academy of Sciences; and in 1830 he was appointed to succeed Lamarck at the museum in the chair of natural history, an honour he had well earned by his important contributions to that science. This he resigned in 1832 to become the successor of Cuvier in the chair of comparative anatomy, which he continued to occupy for the space of eighteen years.

His scientific writings are very numerous, and chiefly relate to the animal kingdom. As a comparative anatomist he proved himself a worthy successor of the celebrated Cuvier. M. de Blainville was found dead in a railway carriage while travelling between Rouen and Caen, May 1. 1850.

Besides a great variety of memoirs published in the *Annales du Muséum d'Histoire Naturelle*, and in similar works, he was the author of *Prodrome d'une Nouvelle Distribution Méthodique du Règne Animal*, 1816; *Ostéographie, ou Description Iconographique Comparée du Squelette et du Système Dentaire des Cinque Classes d'Animaux Vertèbres Récents et Fossiles*, &c.; *Faune Française*, Paris, 1821–1830; *Cours de Physiologie Générale et Comparée*, Paris, 1833; *Manuel de Malacologie et de Conchyliologie*, Strasbourg, 1825–1827; *Histoire des Sciences Naturelles au Moyen Age*, &c., Paris, 1845, 8vo.

BLAIR, DR HUGH, a distinguished clergyman of the Church of Scotland, was born at Edinburgh, April 7. 1718. His father, John Blair, was a merchant in that city, and grandson of the famous Mr Robert Blair, minister of St Andrews, chaplain to King Charles I., and one of the most distinguished clergymen of the period in which he lived.

Blair. After the usual grammatical course at school, Blair entered the humanity class in the university of Edinburgh in October 1730, and spent eleven years at that celebrated seminary, assiduously employed in the literary and scientific studies prescribed by the Church of Scotland to candidates for the ministry.

At this time he commenced a method of study which contributed much to the accuracy and extent of his knowledge, and which he continued to practise occasionally even after his reputation was fully established. It consisted in making abstracts of the most important works which he had read, and in digesting them according to the train of his own thoughts. History, in particular, he resolved to study in this manner; and, in concert with some of his youthful associates, he constructed a very comprehensive scheme of chronological tables for receiving into its proper place every important fact that should occur. The scheme devised by this young student for his own private use was afterwards improved, filled up, and given to the public, by his learned friend Dr John Blair, prebendary of Westminster, in his valuable work entitled *The Chronology and History of the World.*

In the year 1739 Blair took his degree of A.M. On that occasion he printed and defended a thesis, *De Fundamentis et Obligatione Legis Naturæ*, which contains a short but masterly discussion of this important subject, and exhibits in respectable Latin an outline of the moral principles which were afterwards more fully unfolded and illustrated in his *Sermons.*

On the completion of his academical course, after undergoing the customary trials before the presbytery of Edinburgh, on the 21st Oct. 1741 he was licensed to preach the gospel. His public life now commenced with very favourable prospects. The reputation which he brought from the university was fully justified by his first appearance in the pulpit; and in a few months the fame of his eloquence procured for him a presentation to the parish of Colessie in Fife, where he was ordained Sept. 23. 1742. A vacancy having occurred the following year in the second charge of the Canongate of Edinburgh, the young orator was elected by a great majority in July 1743.

In this station Dr Blair continued for eleven years, discharging with great fidelity and success the various duties of the pastoral office; till, in consequence of a call from the town-council and general session of Edinburgh, he was translated from the Canongate to Lady Yester's, one of the city churches, Oct. 11. 1754; and on the 15th June 1758 he was promoted to the High Church of Edinburgh, the most important ecclesiastical charge in the kingdom.

Hitherto his attention seems to have been devoted almost exclusively to the attainment of professional excellence, and to the regular discharge of his parochial duties. No production of his pen had yet been given to the world by himself, except two sermons; some translations in verse of passages of Scripture; and a few articles in the *Edinburgh Review*, a publication begun in 1755, and conducted for a short time by some of the ablest men in the kingdom. But, standing as he now did at the head of his profession, he began to think seriously on a plan for teaching to others that art which had contributed so much to the establishment of his own fame. With this view he prepared a course of lectures on composition; and having obtained the approbation of the university, he began to read them in the college on the 11th of December 1759. The university of St Andrews, moved chiefly by the merit of his eloquence, had, in June 1757, conferred on him the degree of doctor in divinity, a literary honour which at that time was very rare in Scotland. His first course of lectures was received with great applause; and the patrons of the university agreed in the following summer to institute a rhetorical class, under his direction, as a permanent part of their academical establishment. On the 7th April 1762, the king was pleased "to erect and endow a professorship of rhetoric and belles-lettres in the university of Edinburgh, and to appoint Dr Blair, in consideration of his approved qualifications, regius professor thereof, with a salary of L.70." These lectures he published in 1783, when he retired from the labours of the office. Blair.

About the time when he was occupied in laying the foundations of this useful institution, he had an opportunity of conferring what he considered another important obligation on the literary world, by contributing to rescue from oblivion the poems of Ossian. It was by the joint solicitation of Dr Blair and Mr John Home that Mr Macpherson was induced to publish his *Fragments of Ancient Poetry*; and their patronage was of essential service in procuring the subscription which enabled him to undertake his tour through the Highlands, for collecting the materials out of which he afterwards arranged "Fingal," and the other productions which bear the name of Ossian. Soon after their publication Blair gave an estimate of their merits in a "Dissertation," which was prodigiously overrated at the time when it first appeared, and has since, by a natural enough re-action in public opinion, been treated with unmerited neglect. It was printed in 1763; and being regarded as a masterpiece of critical acuteness, as well as of elegant composition, it spread the reputation of its author throughout all Europe, and, for a time, silenced the sceptical doubts which had been raised as to the honesty of Macpherson and the genuineness of Ossian.

It was in 1777 that Blair published the first volume of those sermons which had so long furnished instruction and delight to his own congregation; and this volume having been well received, three other volumes followed at different intervals. These sermons experienced an unusual degree of success, and were circulated rapidly and widely; they were soon translated into almost all the languages of Europe; and His Majesty George III. was graciously pleased, July 1780, to confer a pension of L.200 a-year upon their author.

The sermons contained in the fifth volume were composed at very different periods; but they were in many parts recomposed during the course of the summer 1800, after the writer had completed his eighty-second year. They were delivered to the publishers about six weeks before his death, in the form and order in which they now appear.

The reputation which Dr Blair acquired in the discharge of his public duties was well sustained by the great respectability of his private character. Deriving from family associations a strong sense of clerical decorum, feeling in his heart deep impressions of religious and moral obligation, he was eminently distinguished through life by the prudence, purity, and dignified propriety of his conduct.

In 1748, he married his cousin Catherine Bannatyne, daughter of the Rev. James Bannatyne, one of the ministers of Edinburgh; and by her he had a son who died in infancy, and a daughter who lived to her twenty-first year.

Though liable to occasional attacks from some of the sharpest and most painful diseases that afflict the human frame, he enjoyed a general state of good health; and, through habitual cheerfulness, temperance, and care, survived the usual term of human life. After a brief illness, and retaining to the last moment the full possession of his mental faculties, he expired on the 27th of December 1800, with the composure and hope which became a Christian pastor.

Blair, *James*, an eminent divine, born in Scotland, where he was ordained and beneficed in the Episcopal church. Going to England about the end of the reign of Charles II., he was sent by Dr Compton as a missionary to Virginia, and afterwards by the same bishop made commissary, which was the highest ecclesiastical office in that colony. He formed a design of erecting and endowing a college at Williamsburg, in Virginia; and, in 1693, came to England to solicit

Blair. assistance; when Queen Mary espoused the noble design, and with the concurrence of King William, a patent was passed for erecting and endowing a college by the name of the *William and Mary College*, of which Blair was appointed president, an office which he enjoyed for nearly fifty years. He was also rector of Williamsburg, and president of the council in that colony. He died in 1743, leaving four volumes of discourses on our Saviour's Sermon on the Mount. London, 1742.

BLAIR, *John*, a Scottish author, the contemporary and companion, some say the chaplain, of Sir William Wallace. He attended that illustrious hero in almost all his exploits; and, after his death, wrote Memoirs of the Scottish Champion, in Latin. But time has destroyed this work, which might have thrown great light on the history of a very troubled and remarkable period. An inaccurate fragment of it only has descended to us. It was published, with a commentary, in 1705, by Sir Robert Sibbald; and it is translated in Hume's *History of the Douglases*.

BLAIR, *John*, an eminent Scottish chronologer, was born and educated at Edinburgh, and afterwards went to London, where he became usher at a school. In 1754 he presented to the world his valuable work, *The Chronology and History of the World, from the Creation to the year of Christ* 1753. This volume was published by subscription, and dedicated to Lord Chancellor Hardwicke. In 1755 he was elected a fellow of the Royal Society, and in 1761 of the Society of Antiquaries. In 1756 he published a second edition of his Chronological Tables; and in the following year he was appointed chaplain to the princess dowager of Wales, and mathematical tutor to the Duke of York. His services were rewarded with a prebend's stall in Westminster, and other preferments. In 1763 he attended his royal pupil on a Continental tour, when he visited Lisbon, Gibraltar, Minorca, Italy, and France; and on his return he published an improved edition of his Chronology, which he dedicated to the Princess of Wales. The fate of his brother Captain Blair, who fell in the memorable sea-fight in which Admiral Rodney defeated and took prisoner the French commander Count de Grasse, on the 12th April 1782, is believed to have accelerated his own death, which took place on the 24th of June in the same year.

BLAIR, *Robert*, author of the well-known poem entitled *The Grave*, was the eldest son of the Rev. Robert Blair, one of the ministers of Edinburgh, and the grandson of that Robert Blair who was so conspicuous among the Scottish clergy in the civil wars. He was probably born at Edinburgh about the year 1700, and at the university of that city received the elements of a classical education. He afterwards spent some time on the Continent. Upon his return he took orders, and in 1731 was ordained minister of Athelstaneford, in East Lothian, where he spent the remainder of his life. He died of a fever, Feb. 4. 1746; and was succeeded in his living by John Home, the author of *Douglas*. Blair had five sons and one daughter; the late Robert Blair of Avontoun, Lord President of the Court of Session, being his fourth son.

Blair wrote several other pieces besides *The Grave;* but that poem alone constitutes his title to rank as a poet. It consists of a succession of descriptions and reflections, which have no other connection except what they may derive from their relation to a common subject; but these are interspersed with striking allusions, picturesque imagery, touches of a rude though effective pathos, and a vein of sentiment at once natural and just. The rhythm is often harsh, and the versification frequently devoid of correctness, harmony, and grace; but it has nevertheless a masculine vigour and freshness about it, which more than atone for the defects in the finishing; while, in certain moods of the mind, the air of deep and almost misanthropical melancholy diffused over the whole, proves highly touching and impressive. Campbell, in the *Pleasures of Hope*, has borrowed, with a slight variation, a line from this poem:—

Blair-Athole || Blake.

> ——— its visits,
> Like those of angels, short and far between.

The vigorous, though occasionally rather forced, poetic conceptions of the author of *The Grave*, were finely illustrated, in Cromek's edition published in 1808, by the grandly wild designs of William Blake, engraved by the delicate burin of Schiavonetti. *The Grave* was first printed at London in 1743.

BLAIR-ATHOLE, or BLAIR IN ATHOLE, a village and parish in the county of Perth and district of Athole, 18 miles from Dunkeld, 33 from Perth, and 76 from Edinburgh. Pop. in 1851, 2084. The village has almost completely decayed; but the parish is nevertheless remarkable for its interesting localities, striking scenery, and mineral products, particularly marble, which is found in considerable abundance and of almost every variety of colour, though somewhat coarsely grained, in the valley of the Tilt. One of the most conspicuous objects to the eye of the tourist is Blair Castle, a seat belonging to the Duke of Atholl, and formerly a baronial fortress, though now despoiled of its battlements and other castellated honours. It was occupied by the Marquis of Montrose in 1644; stormed by a party under the command of one of Cromwell's officers in 1653; and gallantly defended by Sir Andrew Agnew, in 1746, when besieged by a portion of the Highland army, until he was relieved by the Hessians under the Earl of Crawford. The falls of Bruar, celebrated by Burns, are two miles to the westward; and the pass of Killiekrankie, famous for the battle which was there fought in 1689, between the Highlanders under Viscount Dundee, and King William's troops under General Mackay, is about an equal distance to the eastward of Blair Castle. The old church of Blair, now in ruins, is said to contain the ashes of Dundee, who fell early in the action.

BLAISE, a military order instituted by the kings of Armenia, in honour of St Blaise the martyr, anciently bishop of Sebasta, and the patron saint of Armenia. Justinian calls them knights of St Blaise and St Mary, and places them not only in Armenia, but in Palestine. They made a vow to defend the religion of the church of Rome, and followed the rule of St Basil. This institution appears to have commenced about the same time with the knights-templars and hospitallers.

BLAKE, ROBERT, a famous English admiral, born in August 1589, at Bridgewater, in Somersetshire, where he was educated at the grammar-school. In 1615 he was entered at St Alban's Hall, Oxford, and subsequently removed to Wadham College. On the 10th of February 1617, he proceeded B.A. In 1623 he wrote a copy of verses on the death of Camden, and soon after left the university. He was early tinctured with republican principles, and disliking that severity with which Laud, then bishop of Bath and Wells, pressed uniformity in his diocese, he embraced puritanism. His natural bluntness causing his principles to be well known, the puritan party returned him member for Bridgewater in 1640. He served in the parliamentary army with great courage during the civil war; but when the king was brought to trial, he highly disapproved the measure, and declared that "he would as freely venture his life to save the king as ever he did to serve the parliament." After the death of the king, however, he fell in wholly with the republican party, and, next to Cromwell, was the ablest officer of whom the parliament could boast.

In 1648–49, Colonel Blake, in conjunction with two officers of the same rank, Dean and Popham, was appointed to command the fleet; and soon after he blockaded Prince Maurice and Prince Rupert in Kinsale harbour. But the latter getting out, Blake followed them from port to port, and at last attacked them in that of Malaga, where he burned and destroyed their whole fleet excepting two ships—the *Refor-*

Blake. *mation*, in which Prince Rupert himself was, and the *Swallow*, commanded by his brother Prince Maurice. In 1652 he was constituted sole admiral, and defeated the Dutch fleet commanded by Van Tromp, Ruyter, and De Witt, in three several engagements, in which the Dutch lost eleven men of war, thirty merchant ships, and, according to their own account, 15,000 men. Soon after, Blake and his colleagues, with a fleet of a hundred sail, stood over to the Dutch coast, and forced the enemy's fleet to fly for shelter into the Texel, where they were blockaded for some time by Monk and Dean, while Blake sailed northward. At last, however, Van Tromp got out, and drew together a fleet of 120 men of war. On the 3d of June the generals Dean and Monk came to an engagement with the enemy off the North Foreland, with indifferent success; but the next day, Blake coming to their assistance with eighteen ships, gained so complete a victory, that if the Dutch had not saved themselves on Calais sands, their whole fleet would have been taken or destroyed.

In April 1653 Cromwell turned the long parliament out of doors, and shortly afterwards assumed the supreme power. Blake observed to his officers on the occasion, "It is not for us to mind state affairs, but to keep foreigners from fooling us." In November 1654, Cromwell sent him with a strong fleet into the Mediterranean, to obtain satisfaction for certain injuries which had been done to our merchants. In the beginning of December Blake entered the roads of Cadiz, where he was treated with all imaginable respect; the Dutch admiral durst not hoist his flag while he was there; and his name had now become so formidable, that the admiral of a French squadron which had stopped one of his tenders when separated in a storm, as soon as he knew to whom it belonged, sent for the captain on board, and drank Blake's health with great ceremony, under a discharge of five guns, and then dismissed him. Blake, on the 10th of March, appeared before Algiers, and demanded satisfaction for the piracies committed on the English, and the release of all English captives. The dey, in his answer, alleged that the ships and captives belonged to private persons, and therefore he could not restore them without offending all his subjects, but that the English admiral might easily redeem them; and if he thought it proper, they would conclude a peace with him, and for the future commit no acts of hostility against the English. This answer was accompanied with a large present of fresh provisions; on receiving which Blake left Algiers, and sailed on the same errand to Tunis. The dey of the latter place, however, not only refused to comply with his request, but denied him the liberty of taking in fresh water. "Here," said he, "are our castles of Goletto and Porto Ferino; do your worst." On hearing this, Blake began, as his custom was when highly excited, to twirl his whiskers; and, after a short consultation with his officers, resolved to bear into the bay of Porto Ferino with his great ships and their seconds. On coming within musket-shot of the castle and the line, he fired on both so warmly that in two hours the castle was rendered defenceless, and the guns on the works along the shore were dismounted, although sixty of them played at once on the English. Observing nine ships in the road, Blake ordered every captain to man his long boat with choice men, to enter the harbour and fire the Tunisians; a service which they effected with the loss of only 25 men killed and 48 wounded, while the admiral covered the operation by playing continually on the castle with his great guns. This daring action spread the terror of his name throughout Africa. From Tunis he sailed to Tripoli; caused the English captives to be set at liberty; and concluded a peace with that government. He then returned to Tunis, upon which the Tunisians begged for peace, which he granted on terms highly advantageous to England. He next sailed to Malta, and obliged the knights to restore the effects taken by their privateers from the English. By these and other great exploits, he raised the glory of the English name to such a pitch, that most of the princes and states in Italy thought fit to pay their compliments to the Protector, by sending solemn embassies to him. Blake.

Blake passed the next winter either lying before Cadiz or cruising up and down the straits. He was at his old station, at the mouth of the harbour, when he received information that the Spanish plate fleet had put into the bay of Santa Cruz, in the island of Teneriffe. Upon this he weighed anchor, with twenty-five men of war, on the 13th of April 1657; and on the 20th came to anchor with his ships off the bay of Santa Cruz, where he saw sixteen Spanish ships moored in the form of a half-moon. Near the mouth of the harbour stood a castle furnished with heavy ordnance; besides which there were seven forts round the bay, with six, four, and three guns on each, and connected by a line of communication manned with musketeers. To make all safe, the commander of the Spanish fleet caused all the smaller ships to be moored close in shore; while the six large galleons stood farther out at anchor, with their broadsides towards the sea. Blake having prepared for the fight, a squadron of ships was drawn out to make the first onset, commanded by Captain Stayner in the *Speaker* frigate; who, on receiving orders, sailed into the bay and fell upon the Spanish fleet, without the least regard to the forts, which kept up a heavy cannonade. As soon as these had entered the bay, Blake followed, and stationed several ships to pour their broadsides into the castle and forts; and these kept up so heavy and well-directed a fire, that, after some time, the Spaniards found their forts too hot to hold them. In the meanwhile Blake joined Stayner, and bravely fought the Spanish ships, out of which the crews were beaten by two o'clock in the afternoon; when Blake, finding it impossible to carry them away, ordered his men to set them on fire; and this was done so effectually, that they were all reduced to ashes except two, which sunk downright, nothing remaining above the water but part of the masts. The English having now obtained a complete victory, were reduced to another difficulty by the wind, which blew so strong into the bay that they despaired of getting out, and for a time lay under the fire of the castle and of all the forts, which must soon have torn them to pieces. But the wind suddenly shifting, they were enabled to work out of the bay, and left the Spaniards in astonishment at the fortunate temerity of their assailants. This action does honour to Blake; and although fortune favoured him in the opportune shifting of the wind, and his situation was, upon the whole, less trying than that of the gallant men under Lord Nelson, who made an attempt on this place, his conduct throughout appears to have been distinguished for the most adventurous daring, and consummate nautical skill. "It was so miraculous," says the Earl of Clarendon, "that all men who knew the place wondered that any sober man, with what courage soever endowed, would ever have undertaken it; and they could hardly persuade themselves to believe what they had done; whilst the Spaniards comforted themselves with the belief that they were devils, and not men, who had destroyed them in such a manner."

This was the last and greatest action of the gallant Blake. Consuming with dropsy and scurvy, he was hastening homewards, but just as he came within sight of land he expired. Disinterested, generous, liberal, and ambitious of nothing but true glory, Blake was one of the prominent characters of an age fertile in great men, and remained untainted with those errors and violences which were then so predominant. Lord Clarendon observes, "that he was the first man who brought ships to contemn castles on shore, which had ever been thought very formidable, and were discovered by him to make a noise only, and to fright those who could be rarely hurt by them. He was the first that infused that degree of courage into seamen, by making them see by experience

Blake || Blane.

what mighty things they could do if they were resolved; and the first that taught them to fight in fire as well as in water."

BLAKE, *William*, an engraver of high but wild genius, was born in Ireland, Nov. 18. 1757. He early evinced a decided predilection for drawing, and his father, a hosier, allowed him to follow his natural bias, and devote himself to the fine arts. He was accordingly sent to London, where he served his apprenticeship with Bazire, at that time one of the most noted engravers of the metropolis. He received instructions in drawing from Flaxman and Fuseli; and though much of his time was engrossed in professional pursuits, he found means to compose many odes, sonnets, and ballads, which gained him a temporary reputation in the world of letters. He was subject to extraordinary hallucinations from time to time, during which he believed that he saw and conversed with the heroes of ancient and modern history. These visions he reproduced with pen and pencil. His conceptions have much grandeur, yet too frequently they bear the impress of the morbid condition of his mind, especially in the latter years of his life. His best works are his illustrations of Young's *Night Thoughts*, and of Blair's *Grave*.

BLANC, MONT, a mountain in Savoy. See ALPS.

BLANCH-Holding, in *Law*, is a tenure by which the tenant is only bound to pay an elusory yearly duty to his superior as an acknowledgment of his right.

BLANCHARD, JACQUES, sometimes called the French Titian, was born at Paris, A.D. 1600. After residing two years at Rome he went to Venice, where he studied assiduously the works of Titian, Tintoret, and Paul Veronese. He imitated the style of these masters with much success, and produced numerous pictures; but his masterpiece is the "Descent of the Holy Ghost," in the church of Nôtre Dame. He died at Paris in 1638.

BLANCHE-FERME, or *Blank farm*, in ancient leases, a farm the rent of which was paid in silver, not in cattle.

BLANCHING, in coinage, the operation performed on the planchets, or pieces of silver, to give them the requisite lustre. See COINAGE.

BLANCO, the name of a cape on the western coast of Africa, in a barren and dreary region, near the southern termination of the Great Desert. It forms the boundary of the Bay of Arguin; and, with the exception of Cape Verd, it is the most westerly point of the continent. The Portuguese discovered it in 1441. The approach to it is not unattended with danger. Lat. 20. 47. N. Long. 16. 59. N. There are several other headlands of this name in Africa, America, &c.

BLANDFORD-FORUM, a market and borough town in the hundred of Coombs-ditch, and county of Dorset, 103 miles from London. It is one of the most handsome towns in the west of England, and is situated on a bend of the river Stour, which flows on its south and west sides. The church and town-hall are elegant buildings. This town has frequently been destroyed by fire, but has always risen with increased beauty. The inhabitants are principally employed in making shirt-buttons, a manufacture that has long formed the staple commodity of the place, and been the source of its prosperity. Market-day, Saturday. Pop. (1851) 3948.

BLANE, SIR GILBERT, *Bart.*, *M.D.*, an eminent physician, born in Ayrshire, August 29. 1749. He studied and graduated at Edinburgh, and was introduced by Dr Cullen to Dr William Hunter, through whom he was appointed private physician to Lord Holdernesse, and was introduced to Lord Rodney. He accompanied the admiral as private physician to the West Indies in 1780. Blane was slightly wounded in the memorable action with De Grasse, and through the influence of Lord Rodney was made physician to the fleet, without having gone through the subordinate grades. He remained in the West Indian fleet until 1783, during which time he became acquainted with the Duke of Clarence, afterwards William IV., who was then a midshipman under Rodney. These distinguished persons, and his own merits, soon introduced him to extensive practice in London: he became a physician to St Thomas's Hospital; a Member of the Royal Society in 1786; and was appointed by that body to deliver the Croonian Lecture in 1788, for which he choose "Muscular Motion" as the subject. His practice and his reputation rose high. In 1790 he resigned his office in the hospital, but was placed at the head of the medical department of the navy in 1795, which he long filled with honour to himself and advantage to the service. He was created a baronet in 1812. In 1819 he published his *Elements of Medical Logic*, a work that has gone through several editions, and which, with his valuable *Suggestions on the use of Lemon Juice as a Preventive of Sea Scurvy*, and his other contributions to medical science, procured him the honour of being elected a member of the French National Institute in 1826. His last publication was a pamphlet entitled *Warning to the British Public against the alarming approach of the Indian Cholera*, in 1831. His latter years were spent in retirement from professional duties; and he occupied this leisure in preparing for the press his *Select Dissertations*, which appeared in 1822, and again in 1834. Sir Gilbert Blane died June 26. 1834, in the eighty-fifth year of his age. (T. S.T.)

Blanes || Blankof.

BLANES, a city of the province of Gerona in Spain, at the mouth of the river Tordera, defended by a castle. Pop. 4397, employed in the fisheries and navigation. Long. 2. 51. E. Lat. 41. 42. N.

BLANK (French *Blanc*), literally signifies white. *Blancus*, or *Blanca*, was a kind of white or silver money, of base alloy, coined by Henry V. in those parts of France which were then subject to England. It was valued at 8d. sterling.

BLANK also denotes a small copper coin, formerly current in France, at the rate of five deniers Tournois.

BLANK-*Verse*, in modern poetry, is a species of verse usually composed of ten syllables, and possessing rhythm, but without rhyme.

BLANKENBURG, a principality forming part of the duchy of Brunswick. Area 170 square miles, comprehending a part of the Hartz Forest; pop. 22,000. The chief city, of the same name, is at the foot of the Blankenstein mountain, on the summit of which, 1130 feet above the city, is situated the summer palace of Louisenburg, with its pavilions and preserves for game, from which is an enchanting prospect over a most romantic district. Pop. 3500. Long. 10. 52. E. Lat. 51. 47. N.

BLANKET, a warm woollen stuff, chiefly used in bedding.

Tossing in a BLANKET, in Latin, *sagatio*, a ludicrous kind of punishment, which Martial describes graphically enough: *Ibis ab excusso, missus ad astra, sago.* Suetonius relates that it was a juvenile diversion of the Emperor Otho to stroll out in the dark, and when he met with a helpless drunken person, to give him the discipline of the blanket. Every body recollects Sancho Panza's misfortune in this way, and the sorrowful sport it proved to the worthy squire of the knight of La Mancha.

BLANKOF, JAN TEUNISZ, an eminent landscape-painter, born at Alkmaer in 1628. His first instructions were received from two obscure artists; but he soon became the pupil of Cæsar Van Everdingen, by whose advice he went to Rome, where he occupied himself in copying the works of the best masters, and was admitted into the society of Flemish painters called Bentvogels, who gave him the name of Jan Maat (*i. e.* comrade), by which he is generally known. His subjects were chiefly river scenes, sea-shores, havens, or ports, which are finely coloured, and executed with a light and free pencil. He died in 1670.

Blaps ‖ Blasphemy

BLAPS. See ENTOMOLOGY.

BLARNEY, a small village of Ireland, in the parish of Garrycloyne, county of Cork, and 3½ miles N.W. of the town of that name. It is pleasantly situated on a small rivulet of the same name, and is chiefly celebrated as giving name to that peculiar kind of eloquence supposed to be so characteristic of the natives of Ireland. The "Blarney Stone," the kissing of which is said to confer this faculty, is pointed out at the top of the castle; but the *real* stone, with the founder's name upon it, is said to be on the northern angle of the castle, about twenty feet from the top.

BLASPHEMY (βλασφημία, from βλάπτω, *I hurt*, and φημί, *I speak*) means literally defamation or evil speaking. In the middle ages it was used to denote simply the blaming or condemning of a person or thing.

Blasphemy is more peculiarly restricted to an indignity offered to the Deity by words or writing. Hence Augustin says, *Jam vulgo blasphemia non accipitur nisi mala verba de Deo dicere.* According to Angelus Clavasius, it is threefold:—1. When something is ascribed to God which is not suitable to his nature; and this is, as the divines call it, a sin *contra misericordiam:* 2. when some attribute which is essential to his Godhead is denied, which is a sin *contra justitiam:* 3. when that which is only proper to the divine Creator of all things is attributed to the creature; and this is termed a sin *contra majestatem Dei.* Lindwood defines blasphemy to be an injury offered to God, by denying that which is due and belongs to him, or by attributing to him what is not agreeable to his nature.

Under the Mosaic law blasphemy was punished with death; and the same punishment was also awarded by the civil law. By the canon law blasphemy was only visited by a solemn penance, and introduced the commutation of corporal punishment into a pecuniary fine. According to Blackstone, the offence of "*blasphemy* against the Almighty, by denying his being or providence, or by contumelious reproaches of our Saviour Christ," is "punishable at common law by fine and imprisonment, or other infamous corporal punishment; for Christianity is part of the laws of England." In like manner, the offence of composing, printing, or publishing a *blasphemous* libel is left to the common law, but on a second conviction the punishment is such as may by law be inflicted in cases of high misdemeanours (60th Geo. III., and 1st Geo. IV., cap. 5, § 4). The power to inflict the sentence of banishment also conferred having been repealed by the 11th Geo. IV., and 1st Will. IV., cap. 73, § 1, and by the 9th and 10th Will. III., cap. 32, § 1, any person, having been educated in, or at any time having made profession of, the Christian religion within this realm, who shall deny one of the persons in the Trinity, or assert that there are more than one God, or deny Christianity to be true, or the holy Scriptures of the Old and New Testament to be of divine authority, is for the first offence rendered incapable of any office, and for the second is adjudged incapable of suing, being executor or guardian, receiving any gift or legacy, and ordered to be imprisoned for three years. These provisions, however, so far as relate to denying the holy Trinity, were repealed by the 53d Geo. III., cap. 160, § 2.

By the law of Scotland, as it originally stood, the punishment of blasphemy was death. By an act passed in the first parliament of Charles II., whoever, "not being distracted in his wits," should curse God or any person of the blessed Trinity was punishable with death; and by a statute of King William's reign (1695, cap. 11), any person reasoning against the being of God, or any person of the Trinity, or the authority of the holy Scriptures, or the providence of God in the government of the world, was to be imprisoned for the first offence until he should give public satisfaction in sackcloth to the congregation; to be punished more severely for the second offence; and for the third doomed to death. The capital punishment was in the year 1696 executed against a young student of divinity named Thomas Aikenhead, whose chief offence was the folly of embarking in speculations beyond his capacity. An account of his trial and condemnation, which excited the indignation of Locke, will be found in the fifteenth volume of the State Trials. Both the Scottish statutes were repealed by the 53d Geo. III., cap. 160, § 3.

Blasphemy ‖ Blasting.

BLASPHEMY against the Holy Ghost. Divines are not agreed with respect to the nature of the crime thus denominated, and the grounds of the extreme guilt ascribed to it. Dr Tillotson maintains that it consists in maliciously attributing to the devil the miraculous operations which Christ performed by the power of the Holy Ghost. But Dr Whitby refers it to the dispensation of the Holy Ghost which commenced after our Lord's resurrection and ascension; and contends that those were guilty of the crime who persisted in their unbelief, and blasphemed the Holy Ghost, representing him as an evil spirit. This crime implied a wilful opposition to the last and most powerful evidence which God had vouchsafed to mankind, and precluded the possibility of a return to faith and repentance.

BLASTING, a term used by the engineer and miner to denote the application of the explosive force of gunpowder in opening or rending rocks, indurated clay, consolidated earth, and the walls of buildings. In quarrying sandstone, consisting of regular layers, the work is performed chiefly by means of the *pick*, the *wedge*, the *hammer*, and the *pinch* or *lever;* but for many kinds of limestone, and for greenstone and basalt, blasting is always resorted to. Most of the primary and transition rocks, and nearly all of the trap or igneous rocks, such as basalt, greenstone, porphyry, amygdaloid, &c., called *primitive*, could scarcely be torn asunder by any other means.

At what period blasting with gunpowder was first resorted to as a *power in mechanics*, is uncertain. Gunpowder was applied to military engines in 1312, but there is reason to believe that its application to the peaceful arts is of a much later date. It may seem strange at this day to propose the *expansive or explosive force* of gunpowder as a new *mechanical power;* but when the lever and the wedge become ineffectual for the purposes of the artificer, he must naturally attach a high value, and be disposed to apply an elevated term, to that instrument or means by which he is enabled, in a very simple manner, to effect his purpose, and overcome the greatest obstructions to his operations.

This agent is no less simple in its application than it is powerful in its effects. It is considered as the result of the sudden extrication of a *permanently elastic fluid* by the ignition of the gunpowder, the extricated gas occupying about 472 times more space than the grains of the powder. Some authors are of opinion that the powder contains only atmospheric air in a state of great condensation, and that, when this fluid is set at liberty, being at the same time highly rarefied by the heat, from the inflammation of the powder, it produces the wonderful effects already mentioned. By others, it is supposed that the air contained in the nitre of the gunpowder is about 236 times denser than atmospheric air, and that, when exploded, it produces an effect proportioned to its condensation; the elastic fluid expanding with a velocity which has been calculated at the rate of about 10,000 feet per second; and its pressure or force, when thus expanding, having been estimated as equal to a *thousand atmospheres*, or as a thousand times greater than the atmospheric pressure upon a base of the same extent. If we apply this product to the pressure of the atmosphere, or at the rate of 14¾ pounds to the square inch, we shall find that the elastic fluid of gunpowder, at the moment of explosion, exerts a force equivalent to 6½ tons upon the square inch of surface exposed to its force. Count Rumford, indeed, estimated this force at 10,000 atmospheres; but we have rather followed the calculations of Hutton, whose opportunities of

Blasting.

experiment, connected with the military college of Woolwich, were unquestionably great.

In Europe, the art of mining was long chiefly confined to Sweden and Germany; but since the disappearance of our thickly wooded forests, and the universal introduction of pit-coal for fuel, and of cast-iron in the arts, Great Britain has made rapid strides towards perfection in the art of mining, and now rivals her Continental neighbours. Here we may allude to the coalworks of Northumberland and Durham, of Cumberland, and the western counties of England and Wales. We may also notice the great extent of similar works in the south-eastern and south-western districts of Scotland. Much of this kind of work is done with the pick and shovel; but without the aid of the expansive force of gunpowder these operations must have been of very limited extent. Other works of no less magnitude than those of coal-mines have been executed in Great Britain, almost wholly by the force of gunpowder. To illustrate more fully the use of gunpowder in mining operations, we may mention the extensive works in tunnelling for railways, and for preserving the level of canals, instead of forming locks, or following a circuitous line of navigation. The bold attempt of blasting rocks under such circumstances was, in this country, reserved for Brindley, the engineer upon the Duke of Bridgewater's canals, who in 1776 completed the first navigable tunnel, at Harecastle in Staffordshire, upwards of a mile in length. Since that period the art of blasting has been extensively practised in a great variety of works, and carried to a wonderful degree of perfection.

Method of blasting rocks.

When a perforation is to be made in a rock for the purpose of blasting with gunpowder, the nature of the rock, and the inclination or dip of the strata, determine the calibre, and the depth and direction of the bore or recipient for the gunpowder. According to circumstances, the diameter of the hole varies from half an inch to two and a half inches, the depth from a few inches to many feet; and the direction varies to all angles from the perpendicular to the horizontal. The implements for the performance of this operation are extremely simple; and the whole operation of boring and blasting rocks is so easily performed, that, in the space of a few weeks, an intelligent labourer may become an expert quarrier. The chisel, or *jumper* as it is technically called, varies in its length and other dimensions according to the work to be performed, and its edge is more or less pointed to suit the hardness or tenacity of the rock to be bored. If the cylindrical hole to be drilled is of small diameter and of no great depth, as often happens, the operation of boring is performed by a single person: with one hand he manages the chisel or jumper, which he keeps continually turning, and with the other he strikes the jumper with a hammer of six or eight pounds weight. But when the hole is of larger dimensions, and of a depth exceeding a foot, it generally becomes the business of one man, in a sitting posture, to hold and direct the jumper, to keep it constantly turning, to supply the hole with water, and occasionally to clean it out, while two, and even three men, with hammers of ten or twelve pounds weight, strike successive blows upon the jumper, until the rock is perforated to the desired depth. To prevent annoyance to the quarriers from the squirting up of the water, a small rope of straw or hemp is simply twisted round the jumper, and kept resting on the orifice of the hole. When the perforation is to be made to a greater depth than about thirty inches, a chisel or jumper is used, varying in length from six to eight feet, pointed at both ends, and having a bulbous part in the middle for the convenience of holding it. It thus beomes a kind of double jumper, and is used without a hammer, with either end put into the hole at pleasure. When a bore of considerable depth is to be made, after the hole has been perforated a few inches with the common jumper, the quarriers lay it aside, and, collecting round the *long jumper*, lay hold of it by the bulbous part, lifting and letting it drop into the hole by its own gravity. In this manner, a hole to the depth of five feet and upwards is perforated by the workmen with ease and with great expedition. A very ingenious and expeditious method, borrowed from the Chinese, is by means of a jumper of very considerable length and weight, suspended and worked by a rope passed over a wheel; and which thus acquires, by the twisting and untwisting of the rope, the requisite rotatory motion. The jumper is hollow, and is so contrived as to receive and retain the *debris*, by means of valves opening inwards. When the boring is completed, the *debris* and moisture are carefully cleaned out, and the charge of powder is put into the hole. In practice, there was formerly no very precise rule for the quantity of the charge, this being regulated at the discretion of the quarrier, according to the tenacity and mass of the rock to be removed; and these circumstances having been previously considered in the dimensions of the bore, it is customary to fill the hole in the proportion of about one-half with gunpowder.

Blasting.

Of late the experiments and observations of Sir John Burgoyne and others, which were conducted more exactly than those of former years, seem to have fully established the propriety of proportioning the charges to the cubes of the *lines of least resistance*, which is the law that theory would assign for rocks of uniform consistence and cohesion. The line of least resistance is the distance between the bore and the open side of the rock, measured in the direction in which the resistance to the explosion is least. In the chalk excavations on the South-Eastern railway, where the blasts were on the largest scale of any work hitherto executed, *the charge in pounds for that kind of work was found in practice to be in the proportion of $\frac{1}{32}$d of the cube of the line of least resistance in feet.* To assist in calculating the charges, it may be useful to remark that 1 lb. of loosely poured powder occupies about 30 cubic inches, so that a cubic foot will weigh about 57½ lb.

After the charge has been introduced, which should be done by means of a copper tube extending down to the bottom of the bore, a long iron, called the *pricker*, is inserted amongst the powder, to be afterwards withdrawn when the priming powder is introduced. While this rod remains, the process of *ramming* or *stemming* the hole is performed by forcing burnt clay, fragments of pounded brick, stone, or any other substance less liable than another to produce sparks of fire on being struck with iron. After a stratum of such matter has been pressed down upon the powder, the hole is filled up with pounded stone or earthy matters of any kind, forced down with an iron punch or rammer of such dimensions that it nearly fills the hole, but having a groove in it to receive the pricker. The rammer being flat at the end which enters the hole, the fragments of stone are pounded by it round the pricker, which must be occasionally turned to prevent it from becoming too firmly fixed to be withdrawn. This wadding or matter laid immediately over the powder is forced down gently at first, lest it should explode prematurely; but as the hole is more and more filled up, the quarrier strikes down the stemmer with more violence, and consolidates the wadding as much as possible, with a view to produce a greater effect by the shot. In this operation consists the chief danger attending the process of blasting; for it must be obvious, that unless the utmost care be taken in forcing down the first portions of the wadding above the powder, there is great danger of such a collision taking place between the stemmer and the pricker, or between either of these and the rock or sides of the hole, as may elicit a spark of fire, and produce an explosion. From this cause, indeed, the most dreadful accidents have sometimes happened to quarriers. It is necessary, as before noticed, frequently to turn the pricker during the process of stemming the shot; and it has been known that, by the friction produced in the mere act of turning it unguardedly, the shot has been fired

Blasting. off. To prevent accident in this way, copper prickers, or, to save expense, prickers composed partly of copper and partly of iron, have been introduced. The copper pricker is certainly much less hazardous; but notwithstanding that this fact is self-evident, and has been clearly established in quarries where copper and iron prickers have been used at the same time, yet, from the greater expense of the copper, and its being more liable to twist and break, it is not yet in universal use.

The hole being now fully charged with the powder and wadding, the pricker is drawn out; and the small tubular space which it leaves is sometimes wholly filled with powder. But with a view to save that expensive article, it is common to insert wheaten or oaten straws filled with powder. These straw tubes may be joined so as to reach any necessary depth, the lower straw always terminating in the root part, where a natural obstruction occurs, or it is artificially stopped with clay. The lower part of the priming straw is pared very thin, so as to insure the inflammation of the charge of powder in the hole. A *slow match*, consisting generally of soft paper, prepared by dipping it into a solution of saltpetre, is then carefully applied to the priming powder. When this match is touched with fire, the quarriers give the alarm to all around to retire to a sufficient distance, so as to avoid accident from the expected explosion. This commonly takes place in about a minute. The priming first explodes, attended only with flame; then the rock opens with a sharp report, and fragments of stone are shot into the air in all directions, from amidst a cloud of smoke. When blasting is carried on in confined situations, where the workmen cannot get speedily out of the reach of the shot, or where adjoining houses, &c., may be in danger of being injured, it is common to load or cover up the rock to be blasted with a quantity of furze or brushwood, loaded with stones or chains to prevent the fragments being driven to a distance.

Tamping. It was long supposed that the more firmly the shot was rammed home, by means of a punch or hammer, the more powerful would be the effect of the explosion. This, we know, was long the conviction of military engineers, and was also a principle invariably adopted by miners, to the great personal hazard of the artificer. It has however been, we think, sufficiently established that a wadding or tamping of loose sand, or of any earthy matter in a dry state, answers all the purposes of the firmest ramming or wadding. Now, as it is in the operation of ramming that accidents most commonly befall the quarrier,—accidents which the use of the copper-pricker cannot altogether prevent,—it is surprising that the use of sand is not universal.

It may be noticed, that in several works this method is adopted, particularly at Lord Elgin's extensive mining operations at Charlestown in Fifeshire, where much attention is paid to the security and comfort of the artificer, as well as to everything interesting to science. The practice of using loose sand instead of pounded stone rammed with force, has been in use at these works for many years,—it is believed since about 1810. The writer of this article has also had considerable opportunities of trying the accuracy of these statements, *as to the efficiency* of sand, at the extensive quarrying operations which became necessary in cutting down a part of the Caltonhill, to form the new approach to the city of Edinburgh, where upwards of 100,000 cubic yards of rocky matter were removed, and gunpowder to the value of nearly L.1000 sterling was expended, chiefly in blasting rock, consisting of whinstone or greenstone, much traversed by calcareous spar. The holes at this work were bored of various dimensions, both as to calibre and depth, and also at all the angles of inclination, from the perpendicular to the horizontal. Trials were here made with holes from three to seven or eight feet in depth, and from an inch to two and a half inches in diameter; and it was invariably found, that when the powder was tamped with sand, the effect in tearing or blasting the rock was as great as when the more common method of ramming with pounded stone was adopted. In the judgment of the contractors, the fragments of rock had a greater tendency to fly to a distance when sand only was employed; but there was as great a bulk of the rock raised by the shot wadded with sand as by that which was rammed in the usual way; and in practice it was found that the shots with sand were not more liable to fail, or *blow* without doing execution, than those which were rammed. It is a fact perhaps as curious and interesting as any connected with the subject, that in both ways the shots fail, and at times blow out, without producing any effect, or being occasioned by any apparent cause. Blasting.

When sand is used immediately above the powder, both the pricker and the rammer are wholly unnecessary: the *primed straw* being inserted into the powder, the sand is poured into the hole, and the shot is ready for the match. But a difficulty occurs in the use of sand, which, though easily surmounted, it may be proper to notice. When the perforation happens to be horizontal, or at more than an angle of 45° from the perpendicular, the priming straw is apt to be injured in filling the hole with sand, an evil to which the pricker is not liable; but this is easily got over by inserting the priming straw into a small cylindrical tube of sheet-iron or copper, while the sand is gently pressed into the hole; and the small tube, which is open at both ends, is afterwards withdrawn. By this means the operation of the horizontal shot is rendered not less sure, and is attended with no greater expense, and little more trouble, than when the bore is perpendicular.

It is proper to observe, however, that although hard stemming of broken stones with punches or hammers is generally disapproved of, there is still some diversity of opinion among writers on the subject as to the use of sand tamping. General Pasley and some other experimenters contend for the superiority of clay over sand in every case, and especially for short bores.

Inflammation of the powder. It has been supposed by some that a more complete inflammation of the powder would take place if it were ignited at the bottom of the hole; but it has been found, from experiment, that gunpowder is even more fully inflamed by applying the fire near the top; for, in firing ordnance, considerable quantities of the uninflamed grains of the powder have been collected, by placing a piece of cloth at a distance from the gun, and allowing the shot to pass through it.

Use of quick-lime. Quick-lime, suddenly slacked, has been suggested as a mode of rending rocks; but this process would in practice be found very defective. In some situations where the explosive effects of gunpowder could not be applied with safety, as in the interior of a building, or for such like purposes, this mode may be resorted to with good effect.

Blasting under water. Blasting with gunpowder under water is necessarily performed in various operations of the engineer, particularly in the excavation of the foundations of piers, and in deepening the entrances of harbours. This used to be done by inserting the charge of powder into the perforated rock by means of a case or cartridge made of tin-plate. The lower part is made to fit the bore in the rock as nearly as may be; and from this a small pipe of the same metal, with the priming powder, is carried to the surface of the water. Here wadding is unnecessary, the pressure of the water upon the tin case superseding the necessity of any; and the explosive effects are generally greater, in proportion to the charge, than those in the open air. The use of tin tubes in submarine blasting has now been wholly abandoned, since the introduction of Beckford's patent fusè, which may with strict propriety be called one of the greatest modern improvements in blasting. The fusè is alike applicable to the removal of rock thirty feet under water, as to all situations where the rock is spongy or full of springs. The charge is contained in water-proof bags, and the fusè, which may be described

Bleaching.

as a perforated water-tight *rope* or *hose*, is attached to the shot-bag; and the inflammable composition in the fusè is thus kept in contact with the charge. The fusè itself is of length sufficient to reach the inside of the diving-bell, or, where that is not used, it must be of length to come above the water. It burns at the rate of from two to three feet per minute. When the fusè is used above water in damp quarries, the shot-bags may, for economy, be made of strong brown paper twice oiled, instead of tarred canvas. It may here be observed, that explosions under water have in some instances been proposed as a mode of attack in marine warfare; and it is presumed that explosions at considerable depths might occasion such an impression on the water, and so disturb the equilibrium of the atmospheric pressure, as to be capable of sinking large ships or floating batteries.

Firing by a voltaic battery.

The mode of firing the charge by galvanism is a modern improvement of very great importance, and has the advantage of being equally applicable to submarine and to ordinary blasting. All that is necessary is to make a small interruption in the conducting wire in contact with the charge. In passing the electric current, a spark is produced at the interruption sufficient to fire the charge. It is instantaneous, and enables the operator to fire simultaneously any number of charges, according to the effect desired to be produced. The application of galvanic firing to submarine charges was first put into practice by General Pasley, in 1839, on the wreck of the Royal George at Spithead. It was also used in the same year, at the Skerryvore rock, by Mr Alan Stevenson. The simultaneous firing of several charges was extensively employed by Mr William Cubitt in the blasting near Dover in 1843. Three charges of 18,000 lb. of gunpowder were *simultaneously* fired by this means. Round-Down Cliff, about 400 feet high, was thrown down, with comparatively little explosion, and covered the beach with 400,000 cubic yards of chalk rock; producing a saving of L.7000 to the South-Eastern Railway Company in this part of their works. This method of blasting is now extensively employed in various parts of the country.

Use of gun-cotton.

Gun-cotton has also been employed in blasting, especially on the Manchester and Huddersfield railway in Standedge tunnel, and on the works in the Stour Valley near Birmingham. It has been stated that gun-cotton produces a much greater effect, weight for weight, than gunpowder, in the proportion of 5 to 1. This seems an exaggeration; but the disruptive effect really seems to be greater from gun-cotton; and as it gives no smoke, in confined situations the workmen are enabled sooner to resume their work.

Blasting screw.

It may also be mentioned, that an instrument called the *Blasting Screw* has been applied with considerable success to the rending or splitting of large trees and logs of timber. It consists of a screw which is wrought into an auger-hole, bored in the centre of the timber; here the charge of powder is inserted, and the orifice of the hole in the log is then shut up or closed with the screw, when a match or piece of cord prepared with saltpetre is introduced into a small hole left in the screw for this purpose, by which the powder is ignited. The application of this screw to the purposes of blasting is not very obviously necessary, because, from what we have seen, it would appear that the auger-hole, being charged with powder and sand, would answer every purpose. One great objection to the process of blasting applied to the rending of timber is, the irregular and uncertain direction of the fracture, by which great waste is sometimes occasioned. It may, however, be necessary to resort to this mode of breaking up large trees, when cut down and left in inaccessible situations, where a great force of men and of implements cannot easily be procured or applied.

Blatta ‖ Bleaching.

See *Treatise of Artillery*, by John Muller; Hutton's *Mathematical Dictionary;* Robins's *New Principles of Gunnery*, by Dr Hutton; Nicholson's *Journal*, vols. xii. and xiii.; *Papers of Corps of Roy. Eng.*, vols. iv. and vi.; *Rudimentary Treatise on Blasting and Quarrying Stone*, by Sir J. Burgoyne, Lond. 1849; Stevenson's *Skerryvore Lighthouse*, Edin. 1848; Pasley's *Memoranda on Blasting; London Electric. Soc. Trans.*, 1839. The reader is also referred to Voltaic Electricity for later methods of Blasting. (R. S.) (T. S.)

BLATTA, a genus of coleopterous insects, belonging to the division of *Orthoptera*, and family *Blattidæ*. The best known in this country are the cockroach, *B. orientalis*, that infests our houses, *B. germanica*, *B. pallens*, *B. americana*. See Entomology.

BLAYE, a fortified seaport town of France, capital of an arrondissement of the same name, in the department of Gironde, on the right bank of the river of that name, and 20 miles N.N.W. of Bordeaux. The river is here about $2\frac{1}{2}$ miles broad, and is defended by Forts Pâté and Medoc; and all vessels inward-bound to Bordeaux, &c., are required to anchor at Blaye, and to exhibit manifests of their cargoes; and vessels outwards generally call here to take in stores or complete their cargoes. It has also a considerable export trade in wine, brandy, corn, oil, soap, and fruits. The town has a strong modern citadel, a handsome public fountain, theatre, hospital, tribunals of primary instance and commerce, agricultural society, &c. Pop. (1851) 4350; of arrondissement, 59,469.

BLAZONRY, the art of deciphering coats of arms; and also that of expressing or describing a coat of arms in appropriate language. The term is said to be derived from the German *blasen, to blow;* it having been customary at jousts and tournaments for the herald to sound a trumpet when he proclaimed the arms of a knight on ushering him into the lists.

BLEACHING

Is the art of depriving cotton, linen, silk, wool, wax, &c., of their colouring matter, and rendering them as white as possible. The word is probably derived from the French term *blanchiment*, which signifies the process of *rendering white.*

History.

1. The ancients, especially in Egypt, where white linen or cotton was a common article of clothing, must at an early period have been acquainted with the method of bleaching that substance; but none of their writers have left us any details on the subject. We know, however, from Pliny, that different plants, and likewise the ashes of plants, which no doubt contained alkali, were employed as detergents. Pliny mentions particularly the *Struthium* as much used for bleaching in Greece. This plant has been considered by some as the *Gypsophila Struthium.* But as it does not appear from Sibthorp's *Flora Græca*, published by Sir James Smith, that this species is a native of Greece, Dr Sibthorp's conjecture that the *Struthium* of the ancients was the *Saponaria officinalis*, a plant common in Greece, is certainly more probable. Mr Parkes, in his *Essay on Bleaching* (*Chemical Essays*, vol. iv. p. 7), says, that Theophrastus states that lime was used by the ancients in bleaching; and that a ship, partly loaded with linen, and partly with lime for bleaching it, was destroyed by the water having accidentally found access to the lime. We endeavoured, with some pains, to verify this quotation; and, accordingly, turned over all the writings of Theophrastus with which we are acquainted, but without being able to find anything bearing the least allusion to it.

Till the middle of the 18th century, the art of bleaching was scarcely known in Great Britain. It was customary to send all the brown linen manufactured in Scotland to Holland to

Bleaching. be bleached. It was sent away in the month of March, and not returned till the end of October, being thus out of the hands of the merchant more than half a year. The principal Dutch bleaching-grounds were in the neighbourhood of Haerlem; and the great success of their bleaching was ascribed to the superior efficacy of their water, which, according to the fashionable theory of the time, was sea-water filtered and rendered sweet by passing through their sand-downs. Indeed, it was long a prejudice on the Continent, that no water was efficacious for bleaching but sea-water.

The Dutch mode of bleaching was to steep the linen for about a week in a potash ley poured over it boiling hot. The cloth being taken out of this ley, and washed, was next put into wooden vessels containing butter-milk, in which it lay under a pressure for five or six days. After this it was spread upon the grass, and kept wet for several months, exposed to the sunshine of summer.

In the year 1749, as we are informed by Mr Parkes (*Chemical Essays*, vol. iv. p. 26), an Irishman, who had learned something of the art of bleaching, settled in the north of Scotland, and established a bleaching manufactory. On applying to the principal Scotch makers of linen, they readily furnished him with a quantity of goods; but after keeping them a whole year, he failed in all his endeavours to bleach them, and the proprietors were obliged to send them to Holland to get the process completed. Next summer his efforts were not more successful; the linen was considerably injured, and even rendered tender by his management, but it was not whitened. Nevertheless, this man by perseverance became in a few years an excellent practical bleacher. He had the merit of introducing the art into Great Britain, and his descendants at this day figure among the higher ranks in the metropolis.

The bleaching process, as at that time performed, was very tedious, occupying a complete summer. It consisted in steeping the cloth in alkaline leys for several days, washing it clean, and spreading it upon the grass for some weeks. The steeping in alkaline leys, called *bucking*, and the bleaching on the grass, called *crofting*, were repeated alternately for five or six times. The cloth was then steeped for some days in sour milk, washed clean, and crofted. These processes were repeated, diminishing every time the strength of the alkaline ley, till the linen had acquired the requisite whiteness.

For the first improvement in this tedious process, which was faithfully copied from the Dutch bleachfields, manufacturers were indebted to Dr Francis Home of Edinburgh, who proposed to substitute water acidulated with sulphuric acid, for the sour milk previously employed. This suggestion was in consequence of the new mode of making sulphuric acid, contrived some time before by Dr Roebuck, which reduced the price of that acid to less than one third of what it had formerly been. It is curious, that when this change was first adopted by the bleachers, there was the same outcry against its corrosive effects as we have seen some years ago, when chlorine was substituted for crofting. No allegation, however, could be worse founded, and it was completely destroyed by the publication of Dr Home (*Essay on Bleaching*), who demonstrated the perfect innocence and the superior efficacy and cheapness of sulphuric acid, when properly applied, as compared with sour milk. Another advantage resulted from the use of sulphuric acid, which was of the greatest importance to the merchant. A souring with sulphuric acid required at the longest only twenty-four hours, and often not more than twelve; whereas, when sour milk was employed, six weeks, or even two months, were requisite, according to the state of the weather. In consequence of this improvement, the process of bleaching was shortened from eight months to four, which enabled the merchant to dispose of his goods so much the sooner, and consequently to trade with less capital. Bleaching.

The bleaching art remained in this state, or nearly so, till the year 1787, when a most important change began to take place in it, in consequence of a discovery which originated in Sweden about thirteen years before. In the year 1774 there appeared in the *Memoirs of the Royal Academy of Stockholm* a paper on manganese, by Mr Scheele. Among other experiments to which he subjected this mineral, he mixed it with muriatic acid, put the mixture in a retort, and applied heat. He perceived a smell similar to that of aqua regia. This induced him to collect what came over in a receiver, and he found it to be muriatic acid, altered in a remarkable manner by the action of the manganese on it. Its smell was greatly heightened, it was become less soluble in water, and it possessed the property of destroying those vegetable colours on which it was allowed to act. M. Berthollet repeated the experiments of Scheele on this new acid in 1785, and added considerably to the facts already known. He showed that this new substance (called by Scheele *dephlogisticated muriatic acid*) is a gas soluble in water, to which it gives a yellowish green colour, an astringent taste, and the peculiar smell by which the body is distinguished. When water impregnated with this gas is exposed to sunshine, it gradually loses its colour, while at the same time a quantity of oxygen gas is disengaged from the water. If the liquid be now examined, it will be found to contain, not the new acid, but common muriatic acid. This experiment Berthollet considered as exhibiting an analysis of the new acid, and as demonstrating that it is a compound of muriatic acid and oxygen. On that account he gave it the name of *oxygenated muriatic acid*, which was afterwards shortened into *oxymuriatic acid*, an appellation by which it was long known among bleachers.

The property which this gas possesses of destroying vegetable colours led Berthollet to suspect that it might be introduced with advantage into the art of bleaching, and that it would enable practical bleachers greatly to shorten their processes. At what time these ideas first struck his mind we do not exactly know; but at the end of a paper on dephlogisticated muriatic acid, read before the Academy of Sciences at Paris in April 1785, and published in the *Journal de Physique* for May of the same year (vol. xxvi. p. 325), he mentions that he had tried the effect of the gas in bleaching cloth, and found that it answered perfectly. This idea is still further developed in a paper on the same substance, published in the *Journal de Physique* for 1786. In 1786 he exhibited the experiment to Mr Watt, who, immediately upon his return to England, commenced a practical examination of the subject, and was accordingly the person who first introduced the new method of bleaching into Great Britain.

Mr Parkes, in his *Chemical Essays*, published in 1815, has mentioned some facts upon this subject, which it will be proper to state. In the early part of the year 1787, Professor Copland of Aberdeen accompanied the Duke of Gordon to Geneva, and was there shown the discolouring property of chlorine gas by M. de Saussure. Mr Copland was much struck with the importance of the experiment; and on his return to Aberdeen in July 1787, he mentioned the circumstance, and repeated the experiment before some eminent bleachers in his own neighbourhood. These gentlemen were Messrs Milnes of the house of Gordon, Barron, and Company, Aberdeen. They immediately began the application of the process to the bleaching of linen on a great scale; and Mr Parkes assures us that they were the first persons who applied the new process to practical bleaching in Great Britain.

New process introduced into Britain by Mr Watt.

But this statement, though it may appear plausible at first sight, is quite incorrect. The writer of this article took the liberty of applying to Mr Watt himself for information on the subject. Mr Watt has preserved copies of all his letters since the year 1782, taken by means of his copying machine; and he allowed the writer of this article to peruse such of them as bore any reference to this subject. Now, two letters were found which entirely set the matter at rest. The first of these is to his father-in-law, Mr Macgregor, dated Birmingham, 19th March, 1787. In this letter he gives a particular detail of the new bleaching process, states its advantages, and says that he had sent Mr Macgregor a quantity of the whitening liquor. The second letter is to Berthollet, and is dated Birmingham, May 9, 1787. The following is a part of that letter, which we have transcribed verbatim: "Je ne sais pas si j'ai encore fait la liqueur acide si fort que vous avez fait, mais je vous donnerois les moyens de juger. Je trouve que 4 onces de mon acide mêlé avec la quantité nécessaire d'alkali de pearl-ash peut blanchir un gros de toile brune, telle comme j'ai vu chez vous. Il est vrai qu'il ne la fait tout-à-fait blanc; mais il le fait aussi blanc, que je puis le faire, même en ajoutant une second dose d'acide. Je bouille la toile par avance dans une solution d'alkali faible; et, à mi blanc, je la bouille une second fois. Je trouve que le savon est meilleur que l'alkali pur pour la second bouillon. J'ai blanchi tout-à-fait le coton, mais je ne suis encore parvenu à blanchir *parfaitement* la toile de lin." The reader will observe that the date of both of these letters is some months before Mr Copland's return from the Continent. M. Berthollet had published his process in 1785, and as Watt had brought it to England in the end of 1786, and had put it in practice, and introduced it into Mr Macgregor's bleachfield, near Glasgow, in the month of March 1787, it is clear that Saussure has no claim to the original discovery, nor Mr Copland to the first introduction of the new process into Great Britain.[1]

Dr Henry quotes a letter of Mr Watt, dated February 23, 1788, in which he says, "I have *for more than a twelvemonth* been in possession *and practice* of a method of preparing a liquor from common salt, which possesses bleaching qualities in an eminent degree; but not being the inventor, I have not attempted to get a patent or exclusive privilege for it." (*Annals of Philosophy*, vi. 423.) This letter alone is sufficient to show that Mr Watt's experiments were of an earlier date than those of Messrs Milnes. He says further, that "at that very time 1500 yards of linen were bleaching by the new process, under his directions." This great experiment was conducted in the bleachfield of his father-in-law, Mr Macgregor, near Glasgow; where, as he wrote to M. Berthollet, soon after, 500 pieces were bleached by the new method, and Mr Macgregor was so satisfied of the importance of the new process, that he had resolved to continue it. Mr Watt made several improvements in the method of M. Berthollet. Instead of employing muriatic acid and manganese, as had been done by Scheele and Berthollet, he had recourse to the cheaper mode of a mixture of common salt, black oxide of manganese, and sulphuric acid. He made use of wooden vessels to hold the water which was to be impregnated with the chlorine, coating them within with a mixture of wax and pitch, which rendered them air-tight, and prevented the gas from acting on the wood. Mr Watt likewise contrived a test to indicate the strength of the water impregnated with chlorine, as far as its bleaching effects were concerned. He took a determinate quantity of the infusion of cochineal, and ascertained how much of the bleaching liquor was necessary to destroy the colour. The strength of the bleaching liquor was obviously inversely as the quantity necessary to destroy the colour. But M. Welter hit upon another method about the same time, which has been considered as preferable, and has in consequence come into general use. He employed a solution of indigo in sulphuric acid, instead of the infusion of cochineal. In other respects the two methods were the same.

Mr Thomas Henry of Manchester began his experiments on bleaching by means of chlorine nearly as early as Mr Watt, and without any previous knowledge of what he had done. He was very assiduous, and very successful in his trials. At a meeting of the bleachers held at Manchester early in 1788, he exhibited half a yard of calico, bleached by the new method, which was considered as superior in whiteness to half a piece of calico bleached by the same process by Messrs Cooper, Baker, and Charles Taylor. In consequence of this exhibition he was applied to by Mr Ridgway of Horwich, to be instructed in the new process: and the instructions which the latter accordingly received were the first step of a series of improvements carried on by Mr Ridgway and his son, with an ability and spirit of enterprise which have raised their establishment to its present extent and importance. (See *Annals of Philosophy*, vi. 423.) These two gentlemen, Messrs Watt and Henry, had the chief merit of introducing the new mode of bleaching into Lancashire, and the neighbourhood of Glasgow.

In the year 1789 M. Berthollet published a memoir on the subject, in the second volume of the *Annales de Chimie*, p. 151. In this memoir, which constituted the first publication on the mode of bleaching by means of chlorine, Berthollet gives a detail of the progress of his experiments, and states the attempts that had been made to introduce the new mode of bleaching into France. M. Bonjour, who had assisted him in his experiments, associated himself with M. Constant, a manufacturer of cloth at Valenciennes, to form a bleaching establishment in that city upon the new plan. But their project was prevented by the prejudices of the inhabitants and by the jealousy of the bleachers, who were afraid of being injured by the introduction of any new improvements. M. le Comte de Bellaing, however, who approved of the project, granted a piece of ground possessed of all the requisite conveniences, but at rather too great a distance from Valenciennes. Mr Bonjour applied to the board of commerce for the exclusive privilege of bleaching for some years, according to the new method in Valenciennes and Cambray, and for two leagues around these places, offering at the same time to explain the new process in all its details to those who wished to make themselves acquainted with it. But the request was refused.

It does not appear from Berthollet's account that the new mode of bleaching had been successfully established in any manufactory in France before the publication of his Memoir. One of the great difficulties in the way of applying chlorine to bleaching, was the very disagreeable and noxious odour which characterized it, and which rendered it not only very offensive, but highly injurious to the health of the workmen. Berthollet describes, at consider-

[1] The late Prof. T. Thomson, when he drew up the preceding historical detail for the Supplement to the Sixth Edition of the Encyclopædia Britannica in the year 1816, thought it right to write to Professor Copland, stating the facts given in the text, and requesting him to say whether they were accurate. Mr Copland returned no answer to the letter. This silence may be considered, we think, as an admission of the accuracy of the statements.

Bleaching

able length, a vessel contrived for impregnating water with it, by M. Welter, and likewise the mode of preparing the gas from common salt, black oxide of manganese, and sulphuric acid. But his improvements, though considerable, were far from obviating the inconveniences complained of. Some method was wanted which should deprive water impregnated with this gas of its smell, without depriving it of its bleaching qualities. The first attempt to accomplish this object originated with M. Berthollet himself.

When he first began to bleach by means of water impregnated with chlorine, he employed that liquid as concentrated as possible; but he found that the texture of the cloth steeped in it was considerably injured. To prevent this effect, he at first added a little alkali to the liquid, in order to saturate a portion of the acid. But he found afterwards that it was better to dilute the liquid with water. Before this last method occurred to him, however, he was requested to go to Javelle, to show the bleachers there the method of preparing the chlorine and making the bleaching liquor. He went twice in consequence, prepared the liquor before the bleachers, and added some potash to prevent the acid from injuring the texture of the cloth. Some time afterwards the manufacturers of Javelle announced in the different journals that they had discovered a peculiar liquid which they called *Lessive de Javelle*, and which possessed the property of bleaching cloth immersed in it for a few hours. This liquid they prepared by dissolving potash in the water which they were going to impregnate with chlorine. The consequence was, that the liquid absorbed a much greater quantity of gas, and might be diluted with a considerable proportion of water, without losing its bleaching quality.

Being disappointed in their attempts to introduce this liquor among the French bleachers, they came over to England, and applied to parliament for the exclusive privilege of supplying the British bleachers with this liquid. The patent was to be given to MM. Bourbollon de Bonneuil and Company. In consequence of this application, a meeting of the bleachers of Lancashire was advertised in the beginning of the year 1788. It was at this meeting that Mr Henry exhibited the half yard of calico bleached according to the new method. Mr Watt had written a letter to Dr Percival on the subject, which was communicated to the meeting. He stated in it that he had been in possession of a new method of bleaching, by means of chlorine, for above a year; that he had learned it from Berthollet, and that he had every reason to believe that the liquor of MM. Bourbollon de Bonnueil and Company consisted of chlorine, or of some preparation of it. In consequence of this meeting, the county members of parliament were requested to oppose the intended monopoly. Mr Watt also exerted all his influence; and Mr Parkes informs us likewise, that one of the Messrs Milnes of Aberdeen, who had been informed of the use of chlorine by Mr Copland, happened to be in the gallery of the House of Commons when the application in favour of the French gentlemen was made. He took immediate measures to inform the principal members that this was not a new process; that he himself had long ago prepared an article equally advantageous; and that he was ready to substantiate the truth of his statement when required. (Parkes's *Chemical Essays*, iv. 62.) In consequence of the united exertions of all these different gentlemen, the bill was thrown out, and the monopoly prevented.

It seems to have been partly in consequence of this application of the French gentlemen that Mr Henry of Manchester was induced to attempt bleaching upon a large scale with chlorine. His attention had been first drawn to the subject by the papers of Berthollet, published in the *Journal de Physique*, during the years 1785 and 1786. He was at that time engaged in a course of lectures on dyeing, printing, and bleaching. An acquaintance with the properties of chlorine, which he had repeatedly had occasion to exhibit in his course of lectures, and the general hints previously thrown out by Berthollet, led him to conclude that the liquor of Bourbollon and Company could be nothing else than chlorine, or some compound of it. His first operations on the large scale consisted in exposing the goods, in a moist state, in air-tight chambers, to the action of chlorine gas. He likewise began to prepare for sale a bleaching liquor, in which the gas was condensed in a very weak solution of potash; which, as we learn from Berthollet, was the very same with the *Lessive de Javelle*. This liquid possessed two advantages over water simply impregnated with chlorine gas. Its smell was less noxious, and it might be employed to whiten printed calicoes without destroying the colours which had been dyed upon the cloth. But these advantages were much more than counterbalanced by equivalent disadvantages. It was found not to go nearly so far as water impregnated with chlorine gas, and when kept for some time it lost its bleaching properties altogether. The reason of this last alteration is now sufficiently understood: the chlorine in the liquid was gradually converted into common muriatic acid and chloric acid; the water containing merely common muriate of potash and chlorate of potash. In consequence of these disadvantages, the addition of potash to the bleaching liquid was soon laid aside. The next attempt to destroy the noxious smell of the liquid, without destroying its bleaching property, was the addition of lime to the liquid. Mr Henry of Manchester was one of the first persons who thought of this addition. On the floor of his air-tight chambers rested a stratum of thin cream of lime, through which the goods were passed by means of a wince; and were afterwards exposed, on quitting the liquor, to chlorine acid gas. Hence the chloride of lime was formed upon the cloth. But this method was objectionable in the case of some coloured goods, the colours of which were injured or destroyed by that earth. It admitted, therefore, of only a partial application.

Bleaching.

Other persons made similar attempts, none of which appear to have been attended with success. But Mr Tennant of Glasgow, after a great deal of most laborious and acute investigation, hit upon a method of making a saturated liquid of chloride of lime, which was found to answer perfectly all the purposes of the bleacher. This was certainly a most important improvement. Without it, the prodigious extent of business carried on by some of our bleachers could not possibly have been transacted. To give some idea of the rapidity with which bleaching is conducted according to the new process, we may mention the following fact, which we state on what we consider as very good authority. A bleacher in Lancashire received 1400 pieces of gray muslin on a Tuesday, which on the Thursday immediately following were returned bleached to the manufacturers, at the distance of sixteen miles, and they were packed up and sent off on that very day to a foreign market. The quick return of capital which is thus made is a benefit entirely to be ascribed to the new mode of bleaching.

In the year 1798 Mr Tennant took out a patent for his new invention, and offered the use of it to practical bleachers, for a fair and reasonable portion of the savings made by its substitution for potash, then in general use. Many of the bleachers, however, used it without paying him, and a combination was formed to resist the right of the patentees. In December 1802, Mr Tennant and Company brought an action for damages against Messrs Slater and Varley, nominally the defendants, but who, in fact, were

Bleaching. backed and supported by a combination of almost all the bleachers in Lancashire. In consequence of this action, the patent right was set aside by the verdict of a jury and the decision of Lord Ellenborough, who used very strong language against the patentees. The grounds of this decision were, that the patent included a mode of *bucking* with quicklime and water, which was not a new invention. It was decided that, because one part of the patent was not new, therefore the whole must be set aside. Had the writer of this article constituted the jury, the verdict would have been very different. Lime was indeed used previous to the patent of Mr Tennant; but it was employed in a quite different manner from his, and he would have allowed all of them to continue their peculiar method without any objection, because it would have been productive of no injury to his emolument. If the very same process as that of Mr Tennant was employed before he took out his patent, there could be no doubt that the process originated with him, and that those who used it had been induced to do so from the information which they derived from him. In the opinion of the writer of this article, Mr Tennant was hardly used, and the words employed by Lord Ellenborough were quite inapplicable to him. But when a very powerful combination is formed against any individual, the sentiments with which they are actuated propagate themselves with rapidity; and it is difficult for the most upright jury to avoid being swayed by prejudices, which are the more formidable, that their existence is not perceived.

In consequence of this decision, the use of liquid chloride of lime in bleaching was thrown open to all, and appears now to be universally employed by the bleachers in Britain. Mr Tennant, thus deprived of the fruits of several years of anxious and laborious investigation, advanced a step farther, to what may be considered as the completion of the new method. This consisted in impregnating quicklime in a dry state with chlorine.[1] He had taken out a patent for this on the 13th of April 1799, and his right fortunately was not contested. He began his manufactory of solid chloride of lime at first upon a small scale, which has been ever since gradually extending, and his manufactory is now the largest of the kind in Great Britain. During the whole period of the duration of his patent he laboured under great disadvantages. The chlorine gas with which the lime was impregnated was obtained from common salt. Now, his patent did not extend to Ireland, in consequence of which manufactures of dry chloride of lime were established in that kingdom. In Ireland the manufacturer obtained his salt duty free, while Mr Tennant was obliged to pay a duty of 7s. 6d. per bushel. Such, however, was the superiority of the methods employed by Mr Tennant, that he was able to compete with the Irish manufacturers in their own country.

In the year 1815, in consequence of the joint application of the bleachers, the duty on common salt, formerly charged upon all bleachers and others who employed that article in the preparation of a bleaching liquid, was taken off, and they were henceforth allowed to use it duty free. But this act, while it affords great advantages to bleachers on a large scale, precludes those who only work on a small scale from making their own chloride of lime; the consumption of the powder, therefore, is likely to increase very much among the little bleachers and calico printers. Its use is also considerable in partially discharging the colour of Turkey red cloth. The method was originally a French invention; but a patent was granted to Mr Thomson, a Lancashire calico-printer, for the process, which, we believe, he imported from Jouy. The method is this: An acid paste, consisting of tartaric acid, or any other acid thickened with gum, is first printed on the Turkey red cloth, which is then passed through liquid chloride of lime. It becomes white only where the acid was applied. On this bleached part any other colour may be applied, and the combinations produced are exceedingly beautiful and striking. Bleaching.

Such, as far as we are acquainted with the subject, is the history of the progress of the new method of bleaching in Great Britain. We have said nothing of the Irish bleachers, because we are not particularly acquainted with the progress of the new method in that country, though we believe that chlorine was tried by the Irish bleachers almost as early as it was in Great Britain. Mr Parkes supposes that Mr Kirwan might have proposed the trial of the new re-agent, in consequence of some suggestion from Scheele or Saussure. (Parkes's *Chemical Essay*, iv. 43.) But we have no evidence that this was the case. Indeed, it would be quite unreasonable to attempt, by such vague suspicions, to detract from the merit due to Berthollet for his original suggestion of the application of chlorine to bleaching, a merit which he has enjoyed without a competitor for thirty years. Scheele was dead before any one attempted to introduce the new gas into bleaching, either in Great Britain or Ireland; and there is every reason for believing that Saussure's knowledge of the bleaching qualities of chlorine originated from Berthollet's publications on the subject in 1785 and 1786.

The *bleaching powder*, or *chloride of lime* as it is usually called, is made by exposing slacked lime to an atmosphere of chlorine gas till it refuse to absorb any more. Unslacked lime is incapable of absorbing this gas; but slacked lime, or hydrate of lime, absorbs it readily. Mr Tennant of Glasgow, the original inventor of the process, whose firm is still by far the greatest in this manufacture in Britain, prepared it by covering the floor of a stone chamber with a layer of slacked lime to the height of a few inches. The stone of which the chamber is built is the Glasgow coal sandstone, which is rendered impervious to the chlorine by being coated externally with a layer of cement, made by melting together wax and rosin in the requisite proportions to make a stiff but very ductile cement. The wooden door of the apartment is then closed and made air-tight. There is an aperture above, which can be occasionally opened; the use of which seems to be to allow the common air of the chamber to make its escape. A mixture of native black oxide of manganese, ground to a fine powder, of common salt, and of sulphuric acid diluted with water, is put into a large leaden vessel, nearly spherical, and furnished at the top with a lid, which fits so as to be air-tight. From this lid a leaden tube passes into the lime chamber, to convey the chlorine gas as it is formed. This leaden vessel is cased on the outside with an iron vessel, between which and the leaden vessel there is an interval. At first the chlorine gas is extricated without any heat being applied; but after the process has continued for some time, a current of steam is made to pass into the inside of the iron case, which heats the leaden still sufficiently high to continue the process till the whole common salt is decomposed, and of course the disengagement of chlorine gas is at an end.

The black oxide of manganese (supposing it pure) is a compound of

1 atom manganese	= 3·5	5·5
2 atoms oxygen....	= 2·0	

[1] The idea of saturating slacked lime with chlorine was first suggested by Charles M'Intosh, Esq. of Cross-Basket, who was at that time a partner of Messrs Tennant and Knox.

Bleaching. By the mutual action of the sulphuric acid and the acid of the common salt it is converted into protoxide of manganese, composed of

1 atom manganese = 3·5
1 atom oxygen..... = 1·0 } 4·5

It therefore loses an atom of oxygen. This atom unites with the hydrogen of the muriatic acid evolved, forming water, and thus converting the muriatic acid into chlorine. It is obvious from this, that if the black oxide of manganese were pure, every 5·5 parts of it would be sufficient to generate 4·5 parts of chlorine, which is the quantity contained in 7·5 parts of common salt. Hence the proportions of black oxide and common salt which ought to be used are 5½ of the former to 7½ of the latter. But the black oxide of manganese employed in this country is never pure. It is always contaminated with a quantity of peroxide of iron, seldom less than one-fourth of the weight of the ore, and often amounting to one-third of that weight. It contains also not unfrequently barytes or lime, which seem to be in chemical combination with a portion of the oxide. On this account it is always necessary to use more than 5½ of manganese for every 7½ of salt. We believe that the quantity of black oxide for every 7½ parts of common salt ought not to be less than 8 parts, to make sure of obtaining the whole chlorine from the common salt.

The black oxide of manganese having a specific gravity of 4·97, and being insoluble in water, speedily falls to the bottom of the leaden still, and would soon cease to convert the muriatic acid into chlorine. To prevent this, there is an agitator in every leaden vessel, which is very frequently moved by the workmen whose province it is to take charge of these stills. By this means the manganese, which is in very fine powder, is mixed with the whole liquid, and thus brought into contact with the nascent muriatic acid, which it deprives of its hydrogen, and thus converts into chlorine.

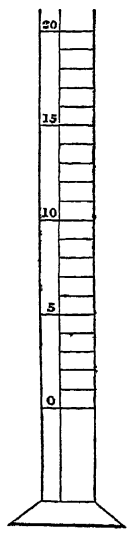
To decompose 7½ parts of common salt completely, 12¼ parts of sulphuric acid of the specific gravity of 1·843 are requisite. This acid should be previously diluted with at least its own bulk of water; or it is better (when the manufacturer of bleaching powder makes his own acid, which is generally the case) to employ the sulphuric acid in the state in which it comes from the leaden chambers, without any artificial concentrations. This, if the acid maker conducts his process properly, may be as high as 1·75. Mr Tennant finds it better to employ a still greater quantity of acid than 12¼ for every 7½ of salt; because the decomposition goes on with the application of less heat, and the leaden stills are much less corroded, than when a smaller quantity of acid and a stronger heat are employed. What remains in the still after the evolution of the chlorine gas is at an end, is a mixture of sulphate of manganese, bisulphate of soda, and free sulphuric acid. It would not do to lose the free sulphuric acid. The residue is therefore mixed with as much common salt as the sulphuric acid is able to decompose, and the whole is gradually fused in a furnace. By this fusion the sulphate of manganese is decomposed as well as the common salt, and there remains sulphate of soda mixed with oxide of manganese and peroxide of iron. Lixiviation gets rid of these two oxides, and leaves a solution of sulphate of soda, which is evaporated to dryness, mixed with pounded coal, and ignited in a reverberatory furnace. By this simple process the Glauber salt is converted into sulphuret of sodium, from which carbonate of soda is extricated by simple and well-known processes.

The bleaching powder, when first prepared, was a bichloride of lime, or a compound of one atom of chlorine and two atoms of lime. But of late years Mr Tennant has improved his process so much, that it is now a chloride of lime, or a compound of one atom chlorine and one atom lime; that is to say, it contains twice the quantity of chlorine which it originally did, and goes twice as far when employed in bleaching; and other manufacturers have been obliged to follow his example. Hence the value of the bleaching powder all over Great Britain is about doubled, while its price is reduced to less than one-half of what it was originally; being sold at present at the rate of threepence per pound, containing nearly half its weight of chlorine. Bleaching.

With respect to the nature of bleaching powder, no experiments have been made sufficiently decisive to remove all doubts. The most commonly received opinion is, that it is a compound of chlorine and lime, or a *chloride of lime*. The objection to this opinion is what happens when carbonate of soda is saturated with chlorine to form the disinfecting liquor used by Labaracque. If the solution be evaporated, a peculiar salt is obtained, which possesses bleaching properties. No chlorine gas is given off during the evaporation. The same phenomena take place when carbonate of potash is saturated with chlorine. From this it has been conjectured, that when chlorine acts upon slacked lime, a certain portion of the lime is converted into calcium, while a portion of the chlorine is converted into *chlorous acid*, or a compound of one atom of chlorine and three atoms of oxygen. On this supposition it is evident that three-fourths of the lime are converted into calcium. The three atoms of oxygen thus evolved convert one atom of chlorine into chlorous acid. This chlorous acid unites with the one-fourth of lime remaining, and converts it into chlorite of lime; while the three atoms of calcium evolved, uniting each with an atom of chlorine, constitute chloride of calcium. According to this view of the subject, the strongest bleaching powder will be a mixture of

3 atoms chloride of calcium = 21
1 atom chlorite of lime..... = 11 } 32

So that about one-third of the weight is chlorite of lime, to which alone the bleaching powers of the substance is owing.



It is rather inconsistent with this opinion, that bleaching powder does not attract moisture from the atmosphere with nearly so much rapidity as might be expected from a mixture containing two-thirds of its weight of so deliquescent a salt as chloride of calcium; unless, indeed, this be prevented by the chloride and chlorite being united into a double salt. When sulphuric acid or muriatic acid, however diluted, are poured into a solution of bleaching powder, chlorine gas is given out in abundance. This seems rather inconsistent with the notion of its being a mixture of chloride of calcium and chlorite of lime; at least no such evolution takes place when these acids are mixed with solutions of chloride of calcium or chlorate of potash.

The bleaching powder, in order to be applied to the cloth, must be dissolved in water; and the quantity employed for the first process consists of a solution of 24 lb. of bleaching powder in 60 gallons of water.

In general, a solution of one pound of bleaching powder in one gallon of water has a specific gravity of 1·05. But the specific gravity of the bleaching powder solution into which the cloth is put is only 1·02. The quantity of liquor of this specific gravity necessary for 700 lb. of cloth is 971 gallons. Hence it is obvious that the quantity of bleaching powder required for 700 lb. of cloth will be 388½ lb.

But the specific gravity of the solution is not sufficient to determine its qualities as a whitening substance. The longer bleaching powder is kept, especially if it be not well shut up from the action of the atmosphere, the less bleaching power does it possess. We have purchased it from apothecaries in London a great many years ago almost totally inert; yet this inactive substance was soluble in water, and was capable of augmenting the specific gravity of the liquid as much or nearly as much as the best bleaching powder whatever; but the liquid was merely a solution

Bleaching. of chloride of calcium. Some other method, accordingly, of judging of the goodness of bleaching powder is necessary for the bleachers. The method commonly employed by the bleachers is the indigo test, first brought into use by M. Welter.

The mode of applying the indigo test followed in this country is by means of the graduated glass tube, figured in the margin, which is known by the name of the *Test-tube*. The method is as follows: One part of the best indigo is dissolved in nine parts of strong sulphuric acid, and the solution is mixed with 990 parts of water, making a solution, $\frac{1}{1000}$th part of which is indigo. Of this liquid a quantity is to be poured into the test-tube, so as to fill it up to 0, or the commencement of the scale. The bleaching liquor whose power is to be tried is then to be dropt gradually in, and mixed with the blue liquor by shaking the tube from time to time till the blue is changed into a clear brown. As soon as this takes place, the degree of the scale to which the mixture reaches is observed, and the figure marked at that degree indicates the strength of the steep-liquor. The lowest on the scale is, of course, the strongest in bleaching power, being capable of destroying most colour. The liquor whose strength is thus ascertained is denominated steep-liquor, of 1, 2, 3, 4, 5, and 6 degrees, the last of which is the weakest ever used for any kind of goods. By adding stock-liquor when the steep-liquor is too weak, and water when too strong, this liquor may be obtained of any strength which is required.

This mode of testing is obviously defective, because we have no good method of determining the goodness of the indigo itself employed as the test; and yet it is well known that different indigoes vary considerably in the quantity of colouring matter which they contain. Various attempts have been made to improve it; but at best it can only be considered as enabling us to compare the relative values of the different varieties of bleaching powder. It can never give us the absolute quantity of oxygen which the bleaching powder is capable of disengaging, upon which its bleaching powers must entirely depend.

Mr Dalton, however, in his paper On Oxymuriate of Lime, in the *Annals of Philosophy*, vol. i. p. 15, has pointed out a process, which, when a little modified, as it has been by Mr Walter Crum, one of the most extensive bleachers in the neighbourhood of Glasgow, answers exceedingly well, and enables us to determine the true quantity of oxygen which the solution of the bleaching powder is capable of yielding to the cloth. Mr Crum's method is this. He dissolves four ounces of green sulphate of iron in hot water, and then adds solution of bleaching powder by small quantities at a time till the smell of chlorine begins to be perceptible. This is a proof that the whole of the protoxide of iron in the four ounces of green vitriol has been converted into peroxide. The strength of the bleaching powder liquid employed by Mr Crum, when the object is to test its value as a bleaching ingredient, is one pound of bleaching powder dissolved in one gallon of water. Of this he adds quantities by $\frac{1}{64}$th of a gallon at a time to the solutions of green vitriol, till the smell begins to become sensible. Six of these measures may be added at once without any risk of evolving any smell; but on the addition of the seventh measure it is necessary to proceed with caution, adding only a little at a time, lest the point of saturation be exceeded. Let us suppose that $7\frac{1}{2}$ measures were necessary to evolve the smell of chlorine; as 64 measures contain one pound of bleaching powder, it is obvious that $7\frac{1}{2}$ measures will contain 820·3 grains. We learn from the experiment, that in the case in question 820·3 grains of bleaching powder, when placed in contact with protoxide of iron, are capable of converting all the protoxide of iron contained in four ounces of green vitriol into peroxide. Now, crystallized sulphate of iron is composed of

Bleaching

1 atom sulphuric acid	5	17·375
1 atom protoxide of iron	4·5	
7 atoms water	7·875	

Consequently four ounces of the salt must contain 396·2 grains of protoxide of iron, to convert which into peroxide will require 44 grains of oxygen. This, of course, is the quantity of oxygen contained in 820·3 grains of the bleaching powder tried. If six measures had been sufficient instead of $7\frac{1}{2}$, then $656\frac{1}{4}$ grains of bleaching powder would yield 44 grains of oxygen. In general, the bleaching powder employed by the bleachers is of about this strength.

Sulphate of manganese might be substituted for sulphate of iron. The result would be the same, excepting that the protoxide of manganese is converted into the native black oxide, by uniting with an additional atom of oxygen. And as crystallized sulphate of manganese is composed of

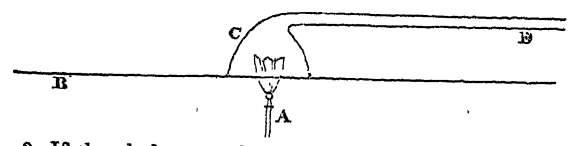
1 atom sulphuric acid	5·0	14
1 atom protoxide of manganese	4·5	
4 atoms water	4·5	

it is obvious that 14 of sulphate of manganese will go twice as far, as a test of bleaching powder, as 17·375 of sulphate of iron. Thence $1\frac{3}{4}$ oz. of crystals of sulphate of manganese will just go as far, as a test for bleaching powder, as 4 oz. of sulphate of iron. The manganese is thrown down in the state of native black oxide; not, however, pure, but every six atoms of it are combined with one atom of lime, constituting a compound which may be called sex-manganite of lime, composed thus:

6 atoms black oxide	33·0	36·5
1 atom lime	3·5	

Prussian blue might also be employed as a test for bleaching powder. A solution of bleaching powder dissolves prussiate of iron, and the solution, when just neutral, is *green*; when there is an excess of bleaching powder the liquid becomes brownish yellow. But prussiate of iron can only be employed as a comparative test in the same way as indigo; although it is preferable to indigo, because it can always be obtained of the same relative strength or purity.

1. *Bleaching of Cotton.*

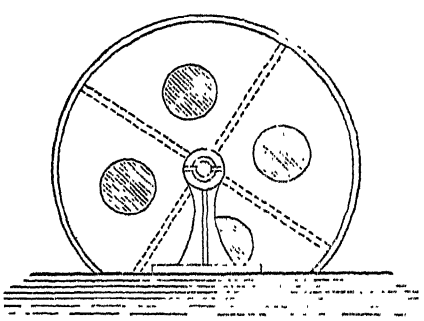


Cotton is a kind of down which fills the seed-pods of various species of plants, particularly the *Gossypium herbaceum*, *hirsutum*, and *arboreum*, from all of which it is extracted in considerable quantity for the purposes of manufacturers. This substance was known to the ancients, and made by them into thread and cloth. Cotton cloth appears to have been generally worn in Egypt and the neighbouring countries at a very early period; and no doubt the plant was cultivated in India and China for similar purposes before the time at which the history of these nations, as far as we are acquainted with it, commences. Pliny gives a short description of the *gossypium* which grew in Upper Egypt, which is sufficient to show us that it was the same with our cotton plant. "Superior pars Ægypti in Arabiam vergens gignit fruticem, quem aliqui *gossipion* vocant, plures *xylon*, et ideo lina inde facta *xylina*. Parvus est, similemque barbatæ nucis defert fructum, cujus ex interiore bombyce lanugo netur. Nec ulla sunt eis in candore mollitiave præferenda." (Plinii *Natur. Hist.* lib. xix. c. 2.) The *byssus* mentioned in the same chapter was probably likewise a species of cotton; though the account of it given by Pliny is not sufficiently precise to enable us to make out the point with certainty.

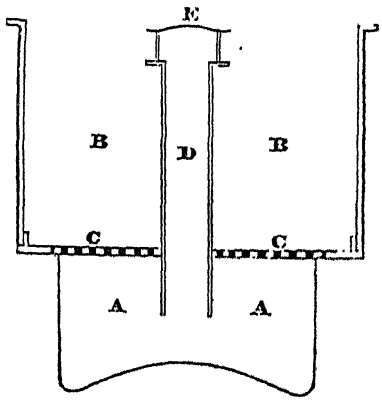
Since the discovery and colonization of America and the West Indies, and our great connection with the East, cotton has become a very common article of clothing in

Bleaching. Europe. The manufacture of cotton cloth in consequence has increased prodigiously, and in Great Britain constitutes one of the great branches of manufacturing industry. The quantity of colouring matter in cotton is much less than in linen, and it is more easily removed. Hence the bleaching of cotton is much easier, and occupies less time, than that of linen. On that account it will be best to give the reader a clear idea of the processes at present followed by the most skilful cotton bleachers in Great Britain. The bleaching of cotton is practised chiefly in Lancashire and the neighbourhood of Glasgow, to which districts the cotton manufacture is almost confined. We shall describe the processes as they are followed in the most extensive bleaching-houses, where they have been brought to the state of greatest perfection. The processes are numerous, though each is sufficiently simple. Let us follow the cotton cloth, from the time that it comes into the hands of the bleacher till it is returned to the merchant fully bleached and ready for sale.

1. The first process is to stamp the proprietor's name upon the end of every piece of goods, that there may be no mistake from the mixture of the cloth belonging to different persons, so that every individual may have his own goods returned to him again without the least risk of error. The substance used for the purpose is *coal-tar*, which distils when pit-coal is heated in iron retorts for the purpose of obtaining coal-gas. It consists of a mixture, or rather solution, of black bituminous matter in naphtha. A quantity of coal-tar is spread over a woollen sieve with a brush. A wooden stamp containing the name of the proprietor of the cloth is pressed against the cloth. It takes up the requisite quantity of coal-tar, and when pressed against the end of the piece makes a black and very distinct impression of the name, which withstands all the subsequent processes to which the cloth is to be subjected without being obliterated; but which might be removed were the stamped part of the cloth to be well washed with soap, and rubbed hard between the hands of the washer. Damask table-cloths, &c., are generally marked with Turkey-red thread, linen goods with nitrate of silver.



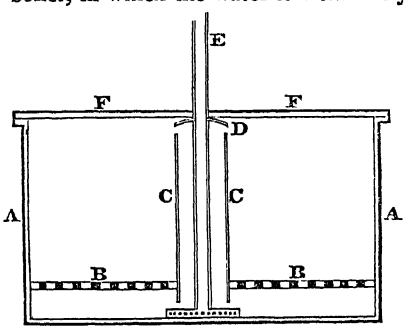
2. The cloth thus marked is in the next place singed, in order to remove the numerous hairs or flocks of cotton, which would have the effect of injuring the look of the cloth. This is usually done by passing the pieces with a uniform velocity over an iron heated red hot. The heat is sufficient to burn off the hairs; but the cloth passes too rapidly to be injured by the hot iron. Some years ago Mr Hall of Nottingham contrived a very ingenious apparatus, by means of which the cloth is singed by coal-gas. Some idea may be formed of the nature of the process by the following imperfect description. A represents the gas flame issuing from a pipe, and B the cloth drawn uniformly along, with the requisite velocity to prevent it from catching fire from the flame; C represents the section of a kind of vessel terminating in a tube D, which is connected with an air-pump kept working during the whole process. The consequence is, that the cloth presses rather forcibly against the bottom of C, and the flame is cut off by the cloth without passing through it, singeing only one side of it.



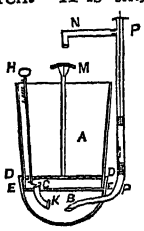
3. If the cloth were thrown into a vessel of water, regularly folded into a number of plies, the water would not be able to penetrate through it, but the central folds would remain dry. To prevent this, each piece of cloth is pulled into a band, by drawing it between the hands so as to give it a slight resemblance to a rope. This band is folded loosely, and tied up by one of its ends into a kind of irregular bundle. These bundles are thrown one after another into a large square cistern or vessel, filled with cold water, and left in that situation till they are completely soaked. In many bleaching establishments, instead of merely soaking the goods, it is customary to steep them in water of a temperature varying from 150° to 170° Fahr., or to boil them for a certain time, to remove the flour or paste dressing which had been applied by the weaver. Muslin goods, however, and in certain bleaching establishments all calicoes, are first thoroughly wetted, and then covered either with pure water, or, better still, with a weak spent alkaline lye of a temperature from 100° to 150°, when they are allowed to ferment for a period of 36 hours. As the dressing consists of sour paste, it is the acetous fermentation which occurs, but it must not be continued longer than 36 hours, otherwise it is apt to run into the stage of putrefaction, which injures the fabric of the cloth. This plan cannot be followed with advantage if the cloth contains many grease stains, or the weaver has applied tallow or oil to his warp during its manufacture. Experience has shown that acids render these fats or oils nearly insoluble in alkaline lye, and should the cloth afterwards be dyed these grease spots attract the colouring matter and cause the cloth to assume a mottled appearance. Bleaching.

The cloth, when removed from the steep vat, or fermenting vat, as the case may be, is either taken to the *wash-stocks* where it is well washed for half an hour, or is put into the *dash-wheel* which effects the washing in from eight to ten minutes.

The dash-wheel is a cylindrical box revolving on its axis. It has four divisions, as shown by the dotted lines, and an opening into each division. Two pieces are put into each, abundance of water is admitted behind, and the knocking of the pieces as they alternately dash from one side of the division to the other during the revolution of the wheel effects the washing. The process lasts from four to six minutes. The object is to remove as much of the weaver's dressing as possible from the cloth before the regular bleaching processes commence.



4. The next process to which the cloth is subjected is boiling with lime. This is done in a large circular *boiler*, or *kier* as it is termed, of which a section is given in the margin. It has two parts; the pan of wrought iron A, set in brick-work, on which the fire acts; and the upper part B, which is of cast iron, and which contains the goods to be boiled. These parts are separated by a cast iron false bottom C, perforated with small square apertures. D is an iron pipe placed in the centre of the kier, and resting upon the false bottom. The liquid in the pan A, from the pressure upon it, does not boil till it is heated considerably above the boiling point. At last it begins to boil in a part of the pipe D, where the pressure is less than in the pan. A mix-



Bleaching. ture of steam and water is formed there, producing a column of lower specific gravity than before. This rushes up the pipe, and is thrown back by the cap E into the boiler, over the cloth, making room for another portion of highly heated liquid, which rising also in the pipe, boils in its turn, making room for a third portion, and so on till the pan is emptied of all its liquid above the bottom of the pipe. The liquid then filters gradually through the goods in the vessel B into the pan, where in a few minutes it is again heated to the requisite degree, and again rushes up the pipe as before. This process lasts about eight hours after boiling commences. The pipe D is often not carried lower than the grating C, to which it is firmly screwed. This operation is usually called "bucking."

Another kind of boiler, in which the water is heated by steam from a separate boiler, is now in very general use. It consists of a cylindrical vessel AA, 9 feet wide, of wood or iron, having a false bottom BB, on which the goods are placed, about six inches from the real one. A small pipe E, in the centre of a wider one CC, conveys the steam from the steam-boiler. When the liquid boils at the bottom, where the steam issues, the steam forces its way up the pipe CC, carrying with it a quantity of the lye, which is thrown back by the small cover D, spreads itself over the surface of the goods, and filters through them into the space below the false bottom, where it is again heated by the steam, re-ascends the pipe CC, and so on in constant succession, till the alkali is exhausted. FF is a wooden cover which prevents the cooling of the materials below a boiling heat.

For some goods these vomiting boiling vats are objectionable, as it is found that exposing the goods at the bottom of the vat to the contact of steam to a certain extent injures their fabric. To get rid of this difficulty some bleachers employ a simple boiler, with a false perforated bottom, set some five inches above the true bottom; or they use a movable rack frame, which they let down with the cloth into the boiler. The most improved boiler, however, consists of a modification of the above described vomiting boilers, of which the accompanying is a sketch. A is the wooden kier or vat, containing the cloth, with false perforated bottom DD. B is the cast iron boiler, with a water-tight top EE. P is the pump, with a movable copper tube N. C K is the pipe of communication between the kier and the boiler, with a valve at each end, that at C acted on by a handle H; that at K opening inwards, so as to allow free egress to the water flowing down from the vat, but shutting by the pressure of the steam in the boiler B, so as to allow no steam to escape through it. The pump is only used till the water in the boiler boils, and is kept constantly at work till the water heats, in order to heat the cloth slowly. As soon as the water boils, and the pressure of the steam which collects in the upper space of the boiler B is sufficient to force the water through the pipe PPN; the piston of the pump is removed, and the boiling fluid forced up is vomited out on the broad plate M, which spreads it equally over the cloth. The fluid as it soaks through the cloth, finds its way into the vacant space between the top of the iron boiler and the false bottom of the vat, and the workman, acting on the handle H, opens the valve C, and allows the liquid to escape into the boiler, where it is heated, and the same process is kept going on so long as is thought necessary.

Bleaching

The quantity of lime used in this process is 1 lb. of lime for every 35 lb. of the cloth. This lime, previously slacked, is mixed with water in a separate vessel, till it has acquired the consistency of cream. A layer of pieces of cloth is deposited in the boiler, and over it is spread equally a portion of this cream of lime. Then another layer of goods is introduced over the former, which is covered with cream of lime as before. In this way the goods and cream of lime are introduced in alternate layers, till the whole has been put into the boiler; then the requisite quantity of water is introduced, and the process of boiling begun.

The colouring matter of the cotton, which it is the object of bleaching to remove, is also acted upon by the lime, but certainly not removed; for the colour of the cloth after it has undergone the lime-boiling is darker than it was before it was wetted at all. Yet it cannot be doubted that this colouring matter has been acted on by the lime, and that it is rendered more easily removable by the future processes to which the goods are subjected.

Some bleachers, in order to shorten the number of processes, instead of boiling with lime alone, boil with lime and soda, in the proportion of from 55 to 65 lb. of each to the ton of cloth. This mixture has the effect of rendering the lye a solution of caustic soda, the lime being rendered inert by combining with the carbonic acid of the soda. This plan is said to answer fully as well as boiling the cloth in the same quantity of lime separately, washing it, and afterwards boiling it separately in the soda lye. In this case the vomiting boiler is not used, but a simple boiler with a false bottom set five inches above the bottom of the iron, and the cloth is kept carefully covered with the lye during the whole process of boiling.

After the lime-boiling, the cloth is carefully washed in the dash-wheel, in order to remove the lime, loaded as it is with impurities, as completely as possible from the cloth. It is then drained, or passed through the squeezers, to expel as much of the water as possible.

5. The cloth, now thrown into loose folds, is next subjected to the action of the bleaching powder or chloride of lime, the solution of which is usually of the strength of 1 on the indigo test-tube, or nearly in the proportion of one pound of chloride of lime to every six gallons of water. The cloth is left in this cold solution about six hours.

It is then taken out and washed with water. It has now assumed a kind of light gray colour. It is not yet white, but much whiter than when it came into the hands of the bleacher.

6. The next process to which it is subjected is called *souring*. Eight gallons of the sulphuric acid of commerce are mixed with 200 gallons of water. This constitutes a liquid having a decidedly sour taste, but too dilute to be in the least corrosive. Some bleachers use their "sour" much more dilute, viz., only $1\frac{1}{4}$ gallon to 300 gallons of water. In this liquid it remains for about four hours. It is then taken out and carefully washed in cold water, to remove the acid as completely as possible. By the *souring* the cloth is rendered much whiter than it was before. The sulphuric acid dissolves and removes the oxide of iron with which the cloth is always more or less contaminated. It removes also the lime which the cloth had imbibed partly from the lime-boiling and partly from the bleaching liquor in which it was so long immersed. The colouring matter of the cloth would seem to combine with the sulphuric acid, and to form a compound much whiter than the uncombined colouring matter itself. That it is not removed is obvious from this, that if the cloth be steeped in an alkaline solution, the dark colour is again in some measure restored.

7. The cloth, after being well washed in cold water, is

Bleaching. immersed in an alkaline lye, in which it is boiled for eight hours, precisely in the same way as was described when giving an account of the lime-boiling. Sixty pounds of soda made caustic by quicklime are used for every 2100 pounds of the unbleached cloth, or for every boiler of a ton's capacity. Some prefer using the soda in its carbonated state, but continue the boiling a little longer.

After this boiling the cloth is again carefully washed in cold water.

8. A solution of bleaching powder is now prepared, two-thirds of the strength of the first bleaching powder liquid, in which the cloth is immersed, and left for five or six hours; but by this exposure the bleaching powers of the liquid are not exhausted, so that by an additional supply of strong liquor it may be rendered fit for another process.

If the cloth to be bleached has red ends, which is sometimes the case, it is carefully washed after this exposure to the action of the bleaching liquor before it is subjected to souring; but if there be no red ends this washing is dispensed with.

9. The next process is a *souring*. The mixture of sulphuric acid and water is nearly of the same strength as before, and the cloth is left immersed in it about four hours, or sometimes not so long. By this process the bleaching of the cloth is completed, for it comes out of the acid steep quite white.

It is a very material thing to remove all trace of the sulphuric acid from the cloth as completely as possible; because any portion of it remaining would corrode and destroy the cloth, especially when it was exposed to the action of heat. To accomplish this necessary result, the cloth is subjected to very careful washing; and this washing process is repeated two several times.

10. Such are the processes of bleaching cotton cloth when of the best quality, and carried to the greatest extent. In many cases several of the processes are omitted; but we have thought it right to detail them all as they are applied to cotton shirting, and to the better cotton fabrics that are to undergo the subsequent processes of calico-printing. But after the bleaching is finished, the cloth is put through a variety of subsequent processes by the bleacher, in order that it may please the eye of the purchaser, and be in the best possible state for commanding a ready sale. Of the most important of these processes it will be requisite to give a short account.

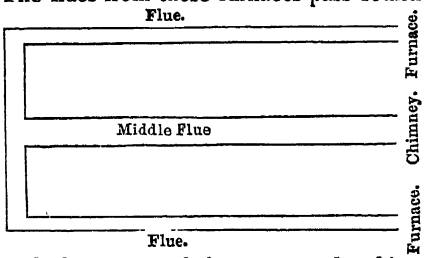
The cloth is *squeezed* after washing, in order to remove a considerable portion of the water which it had imbibed in the washing. This is done by making it pass between two rollers, which by their pressure force out the water. There is something ingenious in this process, simple as it is, that deserves to be noticed. The pieces of cloth, as they come out of the washing wheel, are crumpled together, and frequently entangled in irregular knots. If these knots were allowed to enter between the rollers, they would, from their too great size, be apt to derange them, and might even stop the motion of the machinery altogether. To prevent this from happening, a water cistern, the top of which is on a level with the floor of the room, and which is constantly kept full of water, is placed immediately before the rollers. Over this water the cloth is made to pass on its way to the rollers. By the force necessary to drag it through this water, the piece is stretched, and any wrinkles or knots into which it may have been cast are effectually removed. Thus the cistern of water is made to answer the purpose of one or rather of two workmen. For as two pieces of cloth pass through the rollers at once, were it not for the water, two persons would be required to unfold the cloth, one to each piece.

Plate CVI. fig 1, exhibits a view of the machine called *squeezers*, employed to press as much water as possible from the piece after being bleached. It consists of a cast-iron framing, with two wooden rollers, which are pressed together by a double lever, and made to revolve by means of wheels connected with a shaft from a steam-engine or water-wheel. The wet piece is laid down at one side of the machine, and after passing between the rollers, is folded by a workman stationed at the opposite side. Bleaching.

11. The cloth after the squeezing process is still wet, and is crumpled together like a rope. The next process is to pull out each piece to its breadth. This is done by women, a number of whom are constantly employed in this simple but necessary process. But the edges of the piece still continue folded in. To make them straight, a workman knocks them against a smooth beating stock, first one edge and then the other. By this process the pieces are spread out to their full breadth, and all the folds and wrinkles removed as before the bleaching processes commenced. The pieces are then stitched end to end by women with a sailor's needle, to prepare them for the mangle.

12. The next step is mangling the cloth while still wet, by passing it successively between cylinders, forced towards each other by levers, to which a considerable weight is attached. These cylinders require all to be turned quite true, so as to be perfectly round. One of them is of brass, and two are of wood. By this mangling process the water is equalized throughout the whole piece, the threads are flattened, and the cloth stretched, smoothed, and wound upon a roller, and thus rendered fit for receiving the *starch*

13. Starching is the next process; and though it be well understood, yet it may not be superfluous to give a short sketch of the processes which the bleacher follows, the great object being to unite economy with exactness. Wheat starch would be too expensive; the bleacher therefore satisfies himself with flour. But the gluten of wheat flour renders it unfit for starching. The first step, therefore, is to get rid of that ingredient. Flour is mixed with water in the proportion of one pound of flour to the gallon of water, and allowed to remain for twenty-four hours. A brisk fermentation takes place, an acid, *lactic*, is generated, the texture of the gluten is destroyed, and the water acquires a specific gravity of 1·015. After twenty-four hours, the whole liquid is passed through a sieve. The starch passes along with the liquid, but the bran is retained upon the sieve. The starch is then boiled, a little indigo being added, and water also, so as to proportion the thickness of the liquid to the degree of stiffness which the goods are to acquire.



In many cases the starch is mixed with porcelain clay, about equal bulks of flour and porcelain clay being most commonly employed; though the proportion varies according to circumstances. The starch is applied in the state of a pretty thick paste, while the goods are passed between a pair of rollers.

In other cases equal quantities of porcelain clay and calcined sulphate of lime are mixed with the starch. These substances are applied only on one side; but by the rollers they are forced into the cloth, intermix themselves with its internal structure, and add greatly to its apparent strength and thickness. This method of thickening was undoubtedly intended at first as a fraudulent method of making the purchaser believe that the cloth was much stouter and thicker than it really was. But it has been so long practised, and is now so universally known, that all purchasers must be aware of it, and of course not in any danger of being deceived. But it certainly serves the purpose of making the goods appear much more beautiful, and of a stouter fabric to the eye; and as long as they continue unwashed, they are really stronger than they would be without this artificial dressing. So far it is beneficial; and as it does not enhance the price, the purchasers have no reason to complain of imposition.

Plate CVI. fig. 2, represents the starching machine or stiffening mangle; the middle roller being of brass and the

Bleaching. other two of wood. They are pressed together by means of levers, which are loaded less or more, so as to leave the requisite quantity of starch in the cloth that passes through the rollers. A is the roll of pieces as they come from the water mangle, B a box containing the starch. It is furnished with a roller fixed near the bottom. The piece, in passing under this roller, gets filled with starch, the superfluous part of which is pressed out again by the rollers of the mangle. The piece is then rolled up as before at the back of the machine.

14. The next process is to dry the goods after starching. This is done by hanging them on rails in an apartment heated by a flue passing round the room and down the centre, where it passes into the chimney. There are usually two furnaces, one at each corner of one of the sides of the apartment. The flues from these furnaces pass round the apartment in the way represented in the margin, and uniting in the centre of the side of the room farthest from the furnaces, pass down in one common flue through the centre of the room to the chimney, which is situated midway between the two furnaces. The side flues are usually covered by thin brickwork, but the middle common flue is covered with plates of cast iron. When the cloth is hung up in this apartment the temperature is at first low, but it gradually rises as the goods get dry. The workmen, while employed in hanging up the goods on the rails, &c., which occupies a considerable time, find themselves obliged to throw off part of their clothes, and even sometimes to work naked, with the exception of a pair of drawers or a cloth wrapt round their loins.

15. Nothing now remains but the process of calendering, which gives the goods their final gloss and texture. For this purpose they require in the first place to be damped. This is done by passing them leisurely over a machine, which scatters upon them, as they pass, an infinity of exceedingly small drops. When these drops are first applied, if we hold up the cloth between the eye and the light, we see a great number of small round wet spots, while the greatest part of the cloth is dry. But when the pieces are left for some time standing together in a heap, these spots gradually disappear, and the cloth acquires a uniform dampness, which fits it for assuming the gloss which it acquires by the calendering.

Plate CV. fig. 3, represents the damping machine. A is a box containing a circular brush B, which is made to revolve rapidly, its points just touching a surface of water which is kept of a uniform height. The goods, dry from the stove, are laid down at C; they are pulled in single folds over the surface of the box A, by the pair of rollers D, which are turned round by machinery. A shower of minute drops of water is thus thrown up upon the cloth as it moves over the surface of the box, and the piece, folded up by a workman, is left in a heap till the drops have all disappeared, and the cloth acquired a uniform degree of dampness.

Calendering is making the cloth to pass between a pair of rollers forced against each other by the application of a considerable pressure. During this process the texture of the cloth is made to vary at pleasure. When the goods pass simply between the smooth rollers, the threads are flattened, and the whole piece assumes a soft and silky lustre. When two folds of the cloth are made to pass together through the rollers, the threads make an impression on each other, and assume a wiry appearance, with an intermediate hollow between each. Various degrees of this wiry appearance may be given at pleasure. Bleaching.

Plate CV. fig. 4, represents the *calender*. It consists essentially of a framework, arranged so as to retain a number of rollers parallel, one above another, with levers and pulleys to press them together, and wheels and shafts to make them revolve. Two of these rollers are of cast iron, nicely turned and polished, and three (the largest) of wood with iron centres. The piece of cloth, after being damped, is laid down in front of the calender, and made to pass in various ways between these rollers, after which it is rolled round a cylinder behind, and taken away to be folded.

The goods, after being thus calendered, are folded, and various devices are stamped in red or in blue upon the end of the piece, according to the different markets in which they are to be exposed; for different stamps are requisite for different markets, South America, the West Indies, India, North America, the Mediterranean, &c., requiring each its own device; and, what is very curious, the sale of the goods in a great measure depends upon these stamps; so that if they were absent, the goods, however well prepared, and however excellent in every other respect, would not meet with a ready sale. Everywhere appearances are more attended to than realities. Man is essentially a gullible animal, and quackery is a most important principle in human affairs in general. After the goods have been regularly folded, they are placed piece by piece into a Bramah's press, with a sheet of pasteboard between each; and after a certain interval an iron plate is substituted for the pasteboard, to prevent any inequality in the pile. After sufficient pressure in this machine, they are packed up between boards, to prevent any injury during the carriage, and sent to the merchant or manufacturer to whom they belong.

Such is a sketch of the processes at present followed in the most extensive bleaching establishments in Great Britain for bleaching cotton. The processes altogether amount to about twenty-five, and the whole expense of bleaching and finishing a piece of twenty-four yards in length is tenpence, which is somewhat less than one halfpenny per yard.

When the goods are bleached previous to being printed or dyed, no starching or calendering processes are gone through; but the cloth after receiving its last washing is passed through the squeezers to remove its surplus water. Each piece is then folded separately into a flat square mass, which is knocked by men against the edge of the smooth beating stone, for the purpose of removing all creases from the cloth. It is then hung up on wooden bars in the drying room, and when dry is folded and tied up in parcels of ten pieces each, preparatory to being handed over to the dyers or printers.

The finer muslin goods are not now boiled in lime, as it is proved to injure their fabric, and it is found that the purest whites may be obtained without its aid. A caustic soda lye is used instead, made by boiling for one hour soda with an equal weight of caustic lime. In finishing muslin goods, they are run through water containing some fine starch, and a little fine smalts, which give them a clear shade. They are then pressed nearly dry, and are thorough-dried on a tin cylinder heated by steam.

Book muslins again, after being dried, are passed through starch coloured with smalts; after being wrung out of which they are dried in a heated room, three or four persons stretching each piece from its selvages to keep the piece to its breadth. Sewed dresses, trimmings, &c., are starched in the same way, and kept stretched till they are dry.

The loss of weight sustained during the bleaching of fine cotton cloth in the bleaching houses round Glasgow amounts very nearly to ten per cent. Of this one-half may be considered as weaver's dressing; so that the real loss sustained during the bleaching is not more than five per cent. But when some coarse cotton goods are bleached, we are in-

Bleaching. formed, by a gentleman who tried the experiment, that the loss of weight, independently of the weaver's dressing, amounts to ten per cent.

2. *Bleaching of Linen.*

From the experiments of Mr Lee, who took out a patent about the year 1810, it appears that the colouring matter of flax is not chemically combined with the fibrous threads constituting the bulk of the stalk; but that a chemical combination takes place while the plant is steeped in water. The object of this steeping is to rot the plant, and enable the fibres to separate readily from the stalk. The putrefaction goes on to a considerable extent, and generates so much noxious matter as to destroy any fish which may be in the water where the flax is steeped. This fermentation weakens very considerably the strength of the flax fibres, and even destroys many of them. Mr Lee's process, therefore, if it be practicable on a large scale, would be a prodigious improvement. It would render the flax fibres much stronger, it would increase their quantity, and it would save the expense of the materials employed in bleaching the linen. The late Dr Thomas Thomson was informed that Mr Lee's process had uniformly failed of success when tried in Ireland. If this account were true, it is extremely difficult to explain it. Dr Thomson saw it performed by workmen under his own direction at Old Bow, near London, with the most complete success; not merely upon handfuls of flax, but upon whole fields of it. Indeed the whole is so extremely simple, that we cannot well see how it should fail, if properly conducted. We cannot, therefore, help suspecting that the prejudices of the Irish, with which it would have to contend, have been too powerful for it; but that, as soon as it shall meet with fair play, it will be found just as practicable, and certainly much cheaper and better than the methods at present in use.

That Mr Lee's process has hitherto failed, and that it has been abandoned by the patentee himself, is an undoubted fact; but we cannot avoid suspecting that this was in some measure the fault of the patentee himself. If, instead of attempting the process at Old Bow, at a distance from the linen manufactory, and where no person qualified to appreciate its importance was likely to be near, he had tried it in a place where the linen manufactory existed,—Dundee, for example, or Belfast,—and had he associated with himself some person who was conversant with machinery, and who could have applied a mechanical process more convenient and expeditious than the method of Mr Lee, which was simply beating off the woody fibre by means of wooden mallets,—we cannot but think that the process would have been attended with success. The object of Mr Lee was to save the expense of bleaching linen. For when the flax is separated from the plant without the putrefactive process induced by steeping it in water, nothing more is necessary in order to make it white than simply to wash it in water.

A few years ago Mr Claussen renewed the attempt to prepare flax without steeping, by breaking it by means of machinery, separating the refuse part of the stalk from it, and then by a chemical process splitting the hollow fibres, so as to reduce them to a soft cottony state fit for spinning by means of the cotton-spinning machinery. The fibre was proposed to be split by steeping the prepared flax in a solution of carbonate of soda, and then plunging it into dilute sulphuric acid. The sudden evolution of carbonic acid gas within the hollow tube of the flax was said to have the effect of splitting up the fibre and reducing it to fine flat threads possessing the felting properties of cotton. Sir Robert Kane was commissioned to report on these processes, and his report was printed by the House of Commons, May 20. 1852. It reports that the whole process failed. The machinery for the beating and cleansing of the flax failed to separate it sufficiently from the refuse part of the stalk; and the chemical process for the splitting of the hollow tube only broke up small portions of the exposed ends, leaving the greater portion untouched. Bleaching.

As steeping is uniformly practised, the colouring matter becomes chemically combined with the fibres of the flax, and the process of bleaching must be had recourse to in order to render it white.

Formerly it was the custom to boil linen in lyes of pearl ashes or of soda, wash it, and expose it for several days on the grass, and repeat these several processes five or six times before it was steeped in the "sour" (acid solution), or was exposed to the action of the chloride of lime. Mr Grimshaw, calico-printer, near Belfast, however, recommended an early souring in dilute sulphuric acid, and the process of bleaching has been thereby greatly hastened. Still the bleaching of linen as commonly followed is a very tedious process, according to the plan adopted, requiring from eight to eighteen separate steepings, boilings, and sourings, with as many separate washings, besides exposure to the sun's light on the grass from thirty to sixty days. If the linen is not exposed on the grass to the sun it requires more frequent and longer immersion in the chloride of lime solution to bleach it properly. It cannot be doubted that many of the processes at present followed even in large bleachfields are very faulty, and might be greatly shortened. This will be apparent from casting a glance over the three following plans, each of which produces linen of a pure white. In the first the bleaching is left entirely to the action of the chloride of lime, and is the most scientific. The last is evidently a very faulty plan, and in it, as well as the second, the bleaching is trusted a good deal to the action of the sun's rays. As the processes followed are the same as for the bleaching of cotton, we shall merely give the different plans in the form of a list of the succession of the different operations. The goods bleached are 360 pieces of linen, each 35 yards long.

1st PLAN.—No Exposure on the Grass.

1. Steeped in weak alkaline lye and fermented 36 hours; washed.
2. Boiled in lye of 60 lb. caustic soda 6 hours; washed.
3. Steeped in solution of chloride of lime 15 hours; washed.
4. Soured in sulphuric acid solution 6 hours; washed.
5. Boiled in lye of 60 lb. caustic soda 4 hours; washed.
6. Steeped in solution of chloride of lime 14 hours; washed.
7. Soured in sulphuric acid solution 10 hours; washed.
8. Washed with brown soap on rubbing board; washed.

2d PLAN.—Exposed on Grass.

1. Steeped in weak alkaline lye and fermented 36 hours; washed.
2. Boiled with 60 lb. pearl ashes; washed. Exposed on grass 3 or 4 days.
3. Do. 80 do. do.
4. Do. 90 potashes do. do.
5. Do. 80 do. do.
6. Do. 60 pearl ashes do. do.
7. Soured in dilute sulphuric acid; washed.
8. Boiled with 60 lb. pearl ashes; washed. Exposed on grass.
9. Steeped in chloride of lime solution; washed.
10. Soured in dilute sulphuric acid; washed. Exposed on grass.
11. Boiled with 30 lb. pearl ashes; do. do.
12. Do. 20 do. do.
13. Soured in dilute sulphuric acid; washed.
14. Washed with brown soap on rubbing board; washed.

3d PLAN.—Exposed on Grass.

1. Steeped in weak alkaline lye and fermented 36 hours; washed.
2. Boiled with 60 lb. lime; washed.
3. Do. 50 do.
4. Soured in sulphuric acid, 1¼ gallon to 300 gallons.
5. Boiled with 60 lb. soda; washed. Exposed on grass 3 or 4 days.
6. 7. 8. 9. 10. Do. do. do.
11. Soured in sulphuric acid 1 gallon to 300 gallons; washed.
12. Boiled with 50 lb. soda; washed.
13. Steeped in chloride of lime solution, of strength 1½ by indigo test-tube; washed.
14. Boiled with 50 lb. soda; washed. Exposed on grass.
15. Do. do. do.
16. Steeped in chloride of lime solution, 2 degrees strength by indigo test-tube; washed.

Bleaching.

17. Boiled with 50 lb. of soda; washed.
18. Steeped in chloride of lime solution, 6 degrees by indigo test-tube; washed.
19. Soured in sulphuric acid, 1 gallon to 300 gallons; washed.
20. Scoured with brown soap; washed in pure water.

The loss of weight which linen sustains during bleaching amounts to about one-third of the whole weight of the goods. By the first of the above plans the loss was about 31 per cent., by the second 33 per cent.; but we have not learned the loss by the third plan. Charles Tennant, Esq. of St Rollox, made some experiments in 1831 to determine by which parts of the process the chief loss was sustained during bleaching. The result was that in 1000 parts by weight, linen yarn lost in the fermenting alkaline steep 57 parts

In 4 boils with caustic soda,	70
In 4 steeps with chloride of lime,	170
In 4 steeps in the sour,	18
Total,	315 parts in 1000.

3. *Bleaching of Wool.*

Wool consists of fine filaments or tubes, the external surface of which, instead of being smooth like the tubes of hair, is thrown into transverse corrugations or wrinkles, very similar in appearance to those of the ram's horn. These transverse wrinkles, under a powerful microscope, are seen to be covered with a line of circular apertures or pores, which communicate with the internal part of the filament. Wool is covered with a peculiar varnish or greasy matter which impairs its qualities, and which it is the object of the bleacher to remove. To this varnish the name of "yolk" is given. It is a fatty unctuous matter, chiefly derived from the cutaneous perspiration, but no doubt also secreted by the pores of the wool itself; and it imparts that peculiar heavy odour to sheep with which all must be familiar. From the researches of Vauquelin it would appear that this unctuous varnish consists chiefly of a kind of soap, together with a small quantity of waxy matter, a peculiar odorous animal substance, acetate, carbonate, and muriate of potash, and a little lime. This varnish, in consequence of its soapy nature, is soluble in water, so that washing in pure water would remove the greater portion of it; but it is found more advantageous to remove it by the process termed "scouring."

Scouring is performed by means of an ammoniacal lye, which is thus prepared. Five parts of river or other soft water are to be mixed with one part of stale purified urine, which is found to contain a large quantity of ammonia.[1] This mixture is to be boiled for a short time; and into this, at about the heat of fifty-six degrees, or so that the hand of the workman can be easily held in it for a considerable time, the wool is to be thrown. Four or five pailfuls will generally be sufficient for twenty pounds of wool. After steeping for a short time, the wool is to be stirred about in the mixture continually for about a quarter of an hour or twenty minutes, according to the quantity of greasy matter. It is then to be taken out and drained into a basket, so that the drainings may drop into the vessel in which it was steeped, that nothing may be lost. It must now be completely rinsed by exposing it in baskets to a continued stream of clear water, while a workman is perpetually employed in stirring it with a pole, till the water passes off perfectly clear. The wool is then removed, and a fresh quantity put into the basket, which is to be treated in the same manner. The steeping and rinsing are to be repeated till the wool has attained as great a degree of whiteness as it is capable of receiving from this operation.

In order to conduct this process to the greatest advantage, it is necessary that the workman should attend to the following circumstances:—1*st*, A quantity of fresh lye must be from time to time added to the bath, as the immersion of the wool is found to weaken its power; but it is better not entirely to renew the bath, as the grease abstracted from the wool during its immersion forms with the ammonia of the urine a kind of soap, which much increases the cleansing quality of the bath. 2*d*, Increasing the temperature of the bath will augment its detergent powers, and may sometimes supply the want of an addition of stale urine; but both these circumstances require caution, as too great a degree of heat hardens the greasy matter, and renders it more difficult of solution; and again, too much urine makes the wool harsh. 3*d*, After being much used the bath becomes too foul, and must be entirely renewed. Bleaching.

It is known that the wool is properly scoured by its filaments being smooth, long, slender, white, and perfectly free from foreign substances, and not having lost their natural tenacity.

If this scouring be properly done there is no need of further washings in soaps, or otherwise, till it is subjected to the process called "sulphuring;" and in point of fact it is very rarely passed through any other process. Some, however, recommend that for the finer wools, where a very delicate white is wished, it should be passed through one, two, or more baths of soft soap. No caustic alkaline lyes can be employed, as they destroy the wool altogether, dissolving it, and forming with it a kind of soap.

Scouring, however, is seldom sufficient to bring the wool to that brilliant whiteness which is desirable for some manufactures. This is imparted by means of the vapour of sulphur, or by steeping it in water impregnated with sulphurous acid gas, which is called by the manufacturers *sulphuring*.

The usual method of sulphuring woollen goods is to expose them in a close apartment to the vapour of burning sulphur. The goods are hung on poles so disposed that the vapour can readily pass between the pieces, and when the chamber is filled, a quantity of sulphur placed in very flat and broad dishes is set fire to, and allowed to burn away gradually in the chamber, while every aperture by which the vapour could escape is carefully closed. The acid vapour generated by the combination of the sulphur with the oxygen of the air of the chamber penetrates to every part of the cloth to which it can get access, destroys the colouring matter, and thus completes the bleaching. Everything is allowed to remain quiet till it is supposed that the effect of the sulphurous vapour has fully taken place, which requires from 6 to 24 hours.

After sulphuring the wool has a harsh crispy feel, which is removed by passing it through a weak soap bath. Soft (potash) soap is preferred for this purpose, after being washed with which it is wrung out by the aid of hooks, fixed at each end of the wash-tub, on which the wool is fastened, and twisted round by means of a handle fixed to one of the hooks. It is then hung up and dried.

4. *Bleaching of Silk.*

Silk is the fine glossy filament or thread which the caterpillar of the silk-moth (Phalæna bombyx) spins around it in the form of a cocoon or hollow ball before it assumes the form of a chrysalis. These cocoons are thrown into hot water, and being agitated there the ends of the threads are caught hold of, and several being wound off together into one thread, thus form what is termed "raw silk."

Silk is covered with a kind of varnish, the nature of which was only recently examined by M. Roard. He showed that this varnish, instead of being a gum, as was usually believed, resembled a mixture of bee's wax and oil, with a resinous colouring matter, and in raw silk constituted 23 or 24 per cent. of the weight. The varnish is soluble in water, and affords a solution which forms a lather like soap. The yel-

[1] The detergent property of urine has been long known, and it is frequently employed in washing to save soap. At sea, where fresh water cannot be spared for the purpose of washing, the sailors are accustomed to scour their foul linens in stale urine, which so far cleanses them that a subsequent rinsing in salt water renders them tolerably pure and sweet.

Bleaching. low varnish is of a resinous nature, is insoluble in water, but is soluble in alcohol. The colour is easily discharged either by the sun or by chlorine. Bees' wax also exists in all silks, but the whiter the silk the less wax does it contain.

This varnish, or "gum" as it is technically called, gives the silk a stiffness and elasticity which, for many of the purposes to which silk is applied, it is desirable to remove. This is called "ungumming" by the bleachers of silk. Though many different processes have been suggested for this purpose, none seems to answer so well as the old process of scouring in a weak solution of soap. Mr Roard, however, has shown that if the silk be kept in the soap too long after the varnish is removed, it begins to lose body, and has its qualities impaired, becoming dull, stiff, and discoloured, in consequence of being partly dissolved. He states that white or yellow silks may be completely scoured in one hour in the soap bath, using about 15 lb. of water for each pound of silk, and a suitable quantity of the finest soap. The soap and silk should be put into the water half an hour before it is brought to the boiling point, and then be boiled one hour. They are then removed, wrung out, washed in pure water, and either exposed to the vapour of sulphur or passed through a solution of sulphurous acid gas in water.

The following, however, is the process usually followed by the scourers of silks.

A quantity of water is put into a boiler over a fire, and for every hundred pounds of silk to be scoured, thirty pounds of very fine soap are dissolved. The solution is generally boiled; but before the silk is put into it, the heat must be lowered to about 90 degrees of Fahrenheit, and at this temperature it must be kept during the process. The silks are to be hung in the liquor on rods or frames, and left till the gum is sufficiently destroyed; care being taken to alter their position now and then, so that every part may be exposed to the action of the bath. When perfectly ungummed, they are flexible and of a dull whiteness; in this state they are to be wrung with the pin to clear them of the soapy water, then well shaken, and put into coarse linen bags, in parcels of from twenty to thirty pounds each.

These bags are now to be steeped in a fresh bath, or, as the workmen say, are to be baked. The bath is prepared in a manner and proportion much as before, except that the quantity of soap may be somewhat diminished as the heat is to be increased; for the silk is now to be boiled for an hour and a half, taking care to keep the bags from sticking to the bottom of the boiler, by frequently stirring them with a stick.

For silk that is intended to be dyed, the former steeping in the lukewarm soap bath is unnecessary, and the boiling only is employed, using a greater quantity of soap in proportion to the fineness of the colour. Thus for the ordinary colours, the proportion above laid down, or even less, will suffice; but for the saffron and the poppy and cherry red colours, even 50 pounds are sometimes employed to the 100 pounds of silk.

After boiling, the silk is wrung as before, and then washed thoroughly in a stream of water; they are then examined, and if it appears they are not sufficiently or not uniformly scoured, they must be submitted to a fresh bath.

The white silk usually sold has a bluish shade. This is given it by a bath impregnated with litmus or indigo. This is prepared by dissolving a pound and a half of fine soap in about ninety gallons of water, in which a small quantity of litmus or indigo has been diffused. The bath is heated to about 90 degrees, and the silk is passed through it over rods or reels till it has acquired the requisite shade. Being taken out, it is wrung and dried.

This process gives to the silk the tints known by the names of "silver white," "azure white," and "thread white," according to the depth of shade which has been imparted. The "China white" tint is given by adding annotto to the bath instead of indigo.

From these processes the silk acquires a tolerably clear white, but the highest degree is given to it by the action of the sulphurous acid, either in the state of vapour, as is usually practised, or by immersing it in the liquid acid, according to the method of Mr O'Reilly. Bleaching.

At Lyons no soap is used in the tinting process; but, after being boiled, the silk is washed, wrung dry, sulphured, and then passed through water properly blued.

Silk intended for blonds and laces is not deprived of its natural varnish, as it is essential that such silk should preserve its natural stiffness. The whitest raw silks are therefore selected for this purpose; they are steeped, then rinsed in water containing a very little soap, wrung dry, exposed to the vapours of sulphur, and then tinted by being passed through water properly blued.

Dr Ure mentions that the Abbé Collomb in 1785 scoured silks by boiling them for eight hours in pure water. The silks were stronger than after the usual process, but were not so white. It may be mentioned that a patent has lately been taken out in England for bleaching silks by means of steam.

5. *Bleaching of Rags for the Papermaker.*

The rags to be whitened should be well washed in the engine, and when reduced to what is called half-stuff, the water should be run off, leaving just enough to allow them to be easily turned. While the rags are thus preparing, a solution of the bleaching powder is to be got ready, by putting the powder into a pitcher or other convenient vessel, and pouring upon it two or three gallons of water, stirring and bruising it well, till everything soluble is taken up. After it has stood some time to allow the insoluble sediment to fall down, it is fit for use, and the pure solution should be poured into the engine. The sediment may be repeatedly washed with fresh portions of water to exhaust any remains of soluble matter, which alone is useful in the whitening process. After the bleaching liquor is put in, the stuff is allowed to turn in the engine for ten or fifteen minutes. It is then emptied into a chest or puncheon where it should lie from six to twelve hours, by which time the required degree of whiteness is attained. It is then thoroughly washed to free it from all remains of the chloride. The quantity of powder usually allowed is from two pounds to four pounds for every hundredweight of rags, in proportion to the whiteness required and the difficulty of whitening the stuff.

Rags containing dyed colours to be discharged, should be well washed, and reduced to half-stuff. They are then removed from the engine and put into a puncheon made water-tight, but having a sufficient opening in the side to admit with ease the putting in and taking out of the stuff, and capable of being shut up so as to retain the water. Having put the stuff into this puncheon, take for every hundredweight of the rags a solution containing from five to eight pounds of bleaching powder, according to the strength and fixedness of the colours to be discharged. Pour the solution into the puncheon among the stuff, allowing liquid enough to let the stuff float easily, and for each pound of powder used add half a pound of sulphuric acid. Then shut up and secure the opening so as to make the puncheon air-tight; then turn the puncheon round upon its axis, by means of a crank fixed at one end of it. Moving it in this manner gives facility and uniformity to the discharging process.

6. *Bleaching of Straw.*

The fine wheat-straw used in Tuscany, and elsewhere, for straw-plaiting, after being cut, dried, and tied up in bundles, is stacked for a month. It is then spread out in a meadow, and exposed to the action of the sun and air, being frequently turned during that period. The lower joint of the straw is then pulled off, leaving only the upper joint with

Bleaching || Bled-el-Jereede.

the ear attached; this being the only part of the straw used. It is then steamed, and after that exposed to the vapours of sulphur, which complete the bleaching. It is then tied up in bundles, in which state it is ready for the market. In this country straw is usually bleached by the vapours of sulphur alone; but Dr Ure mentions that a solution of the chloride of lime may be advantageously substituted.

7. Bleaching of Yellow Wax.

Before the discovery of chlorine and its application to bleaching, this was effected by exposing the yellow wax, formed into thin cakes, to the free action of the air, sun, and dew. The chlorine, however, as being far more expeditious, is to be preferred.

In the bleaching of wax it is proper to employ the simple gas, and its action would be the most effectual if used in the gaseous form. For this purpose a pneumatic tub, with a cover secured in the manner recommended by Rupp, is the most proper. This should be filled with water, and the wax, shred very fine, must be introduced, and the gas made to pass through the water, while the agitator is kept in constant motion. In the course of an hour or two the wax will be bleached, may be separated from the water, melted, and formed into cakes.

8. Of Whitening and Cleaning Prints, Maps, Books, and other Articles of Paper.

The chlorine was first applied to this purpose by Chaptal, and the method has been employed with the greatest success by Vialard and Heudier.

Gas might be used for this purpose, but it is safer and equally efficacious to employ it in the liquid form.

Simple immersion in chlorine, letting the article remain in it a longer or shorter space of time, according to the strength of the liquid, will be sufficient to whiten an engraving. If it be required to whiten the paper of a bound book, as it is necessary that all the leaves should be moistened by the liquid, care must be taken to open the book well, and to make the boards rest on the edge of the vessel, in such a manner that the paper alone be dipped in the liquid; the leaves must be separated from each other, in order that they be equally moistened on both sides.

The liquor assumes a yellow tint, and the paper becomes white in the same proportion. At the end of two or three hours the book may be taken from the acid liquor and plunged into pure water, with the same care and precaution as recommended in regard to the acid liquor, that the water may exactly touch the two surfaces of each leaf. The water must be renewed every hour, to extract the acid remaining in the paper, and to dissipate the disagreeable smell.

By following this process there is some danger that the pages will not be all equally whitened, either because the leaves have not been sufficiently separated, or because the liquid has had more action on the front margins than on those near the binding. On this account the practice followed by book-binders, when they wish to whiten printed paper, is to be preferred. They destroy the binding entirely, that they may give to each leaf an equal and perfect immersion; and this is the second process recommended by M. Chaptal.

Bleaching || Bled-el-Jereede.

"They begin," says he, "by unsewing the book and separating it into leaves, which they place in cases formed in a leaden tub, with very thin slips of wood or glass, so that the leaves, when laid flat are separated from each other by intervals scarcely sensible. The acid is then poured in, making it fall on the sides of the tub, in order that the leaves may not be deranged by its motion. When the workman judges, by the whiteness of the paper, that it has been sufficiently acted upon by the acid, it is drawn off by a cock at the bottom of the tub, and its place is supplied by clear fresh water, which weakens and carries off the remains of the acid, as well as its strong smell. The leaves are then to be dried, and, after being pressed, may be again bound up.

"The leaves may be placed also vertically in the tub; and this position seems to possess some advantage, as they will then be less liable to be torn. With this view I constructed a wooden frame, which I adjusted to the proper height, according to the size of the leaves which I wished to whiten. This frame supported very thin slips of wood, leaving only the space of half a line between them. I placed two leaves in each of these intervals, and kept them fixed in their place by two small wooden wedges, which I pushed in between the slips. When the paper was whitened, I lifted up the frame with the leaves, and plunged them into cold water, to remove the remains of the acid, as well as the smell. This process I prefer to the other.

"By this operation books are not only cleaned, but the paper acquires a degree of whiteness superior to what it possessed when first made. The use of this acid is attended also with the valuable advantage of destroying ink spots. This liquor has no action upon spots of oil, or animal grease; but it has been long known, that a weak solution of potash will effectually remove stains of that kind.

"When I had to repair prints so torn that they exhibited only scraps pasted upon other paper, I was afraid of losing these fragments in the liquid, because the paste became dissolved. In such cases I inclosed the prints in a cylindrical glass vessel, which I inverted on the water in which I had put the mixture proper for extricating the oxygenated muriatic acid gas. This vapour, by filling the whole inside of the jar, acted upon the print, extracted the grease as well as ink spots, and the fragments remained pasted to the paper."

Vialard and Heudier by this process restored several of the most valuable books of the French national library, and we believe they were the first who carried Chaptal's process into actual execution. (T. T.) (J. S—K.)

BLED (or BELED) EL-JEREEDE, an extensive territory in Africa, immediately to the south of the kingdoms of Algiers and Tunis, from which it is separated by the range of the Atlas. On the southern side it passes gradually into the great desert of the Sahara, the character of which it in some degree partakes. The northern districts indeed are tolerably watered by streams descending from the Atlas, some of which spread even into considerable rivers, that never reach any receptacle, but are either absorbed by the sands or diffused into shallow and extensive lakes. Some of the districts thus irrigated possess a considerable share of fertility; but the greater number labour under severe drought, which always increases till the country assumes the arid character of the desert. It is only in a few spots that the grains and fruits which are carried to such perfection in Barbary can be raised with advantage. The date, peculiarly adapted to dry soil, is almost the exclusive product, and forests of the tree producing it cover a great extent of the territory. It forms the food of the people, and their chief article of export, by which they obtain the few foreign luxuries in which they indulge. They likewise rear sheep and goats, and employ themselves in the chace of the ostrich for the sake of its valuable feathers, which form another article of trade. The name of the country is commonly supposed to be derived from *jerid*, a date; but Dr Shaw conceives that *jeriddé*, dry, is the true etymology.

The people of this district, exposed to the direct rays of a burning sun, are lean and swarthy, with a shrivelled ap-

Bleeding ‖ Blind.

pearance, and their eyes are frequently subject to inflammation, in consequence of the reflection of the rays from a naked arid soil; yet the plague, which commits such havoc in the cities of Barbary, never attacks the Bled-el-Jereede, notwithstanding the constant intercourse between the two places. The inhabitants in general reach a good old age, of which they often exhibit the appearance without any decay in the faculties of body or mind. They are composed of a mixture of Arabs and native Africans, partly living in rude villages, partly wandering in tents. In some places, where rain scarcely ever falls, the people construct their dwellings of the salt with which the territory abounds; but a casual shower often melts these frail habitations. Another characteristic feature is the occurrence of water, which is almost uniformly found on digging to a certain depth beneath the arid surface, and to which the natives give the appellation of the sea under ground. When the soil is dug into, it rushes forth, sometimes in such quantities as to drown the workmen employed. By bringing up this subterranean store, fertility is communicated to the most barren soils; but the labour of the operation is such that it can be practised only to a limited extent.

Bleeding of a Corpse, a pretended phenomenon once superstitiously believed to be exhibited by the bodies of persons murdered, which, on the touch or even the approach of the murderer, appeared to bleed. This circumstance was formerly admitted in England and elsewhere as a detection of the criminal, and proof of the fact.

BLEIBERG, a town in the circle of Villach in Illyria, remarkable for the lead mines whence it derives its name. The produce of the lead mines is about 2000 tons annually; besides which there are valuable copper mines in the adjacent mountains. The town contains 3700 inhabitants.

BLEMYES, or Blemmyes, a nomad tribe of Ethiopia, fabled to have had no heads, their eyes and mouths being placed in their breasts. (See Augustin, *De Civ. Dei*, xvi. 8.)

BLENDE, in *Mineralogy*, a sulphuret of zinc, and by much the most common ore of that metal. In its crystalline form, its colour, and appearance, this mineral varies extremely. The most common varieties, certainly, are brown or black, but a fine oil-green transparent species occurs at Schemnitz in Hungary; another of a rich hyacinth-red colour is met with at Klapruck in Transylvania; and a third in botroidal concretions, having a white fibrous structure, is found near Fowey in Cornwall. The fibrous blende of Przibam in Bohemia possesses, after a fresh fracture, a lustre almost metallic, and is peculiar, from the portion of cadmium with which it is associated. The crystalline form of blende is tessullar, and often presents the faces of the dodecahedron, to which figure the larger cleavable varieties are easily reducible by mechanical division. The surfaces of the crystals are extremely resplendent, and have at times a strong adamantine lustre. They yield to the knife, are rather brittle, and possess a specific gravity equal to 4·07. Blende, according to Thomson and Berthier, is composed of

Zinc	59·09	70·4
Iron	12·05	4·0
Sulphur	28·86	35·6

When strongly heated in the oxidating flame of the blowpipe, it gives off vapours of zinc, which form a coating on the charcoal; but it does not melt. It is soluble in nitric acid, during which process sulphuretted hydrogen is disengaged. Some varieties are phosphorescent in the dark when rubbed, and present that phenomenon even although the experiment be repeated under water. The sulphuret of zinc occurs both in primitive and secondary rocks, and is an almost constant accompaniment in the veins of lead, iron, and copper, associated with quartz, calcareous spar, or barytes. Great quantities of blende are found in Derbyshire and Cornwall, at Alston Moor and Lead Hills, at Klapruck in Transylvania, and Freyberg in Saxony; in Hungary, Bohemia, Silesia, and the Hartz. It is used in some places for obtaining the zinc in combination with it, but is otherwise an unimportant ore.

Blenheim ‖ Blind.

BLENHEIM (German *Blindheim*), a village of Germany, in the kingdom of Bavaria, and circle of Suabia, remarkable as the scene of the defeat of the French and Bavarians on the 13th of August 1704, by the English and their confederates under the Duke of Marlborough and Prince Eugene. See Britain.

Blenheim House, a princely mansion erected for the Duke of Marlborough at Woodstock, near Oxford, as a testimony of national gratitude, and, with the manor of Woodstock, settled on the duke and his heirs, in consideration of the eminent services performed by him, and more especially of his decisive victory at Blenheim over the French forces under Marshal Tallard. The sum of L.500,000 was voted by parliament for the purchase of the manor of Woodstock, and the erection of this edifice. Blenheim, notwithstanding the malicious strictures of Swift, and the unjust criticisms of Evans and Walpole, is a magnificent pile, built by Sir John Vanbrugh, in a massive Italo-Corinthian style. Walpole's taste in architecture may well be distrusted, when it produced the crudities of Strawberry-hill. The front of Blenheim from wing to wing extends to 348 feet; and the great hall is a lofty noble apartment, in good proportions. In the house are a considerable number of fine pictures,—the most noted of which are, "The Young St Augustine and Pope Gregory," by Titian; "Europa," "Esther," and "The Massacre of the Innocents," by P. Veronese; "St Jerome," by Tintoretto; "Magdalen," by C. Dolce; many historical subjects, by Rubens; portraits by him and Vandyk; "The Woman taken in Adultery," "Isaac blessing Jacob," by Rembrandt," &c.

BLENNORRHŒA (βλέννα and ῥέω), an inordinate secretion or discharge of mucus; more particularly applied to that of the urethra and vagina.

BLENNY. See Ichthyology, *Index*.

BLEPHARIS, a genus of acanthopterygious fishes, of the family of Scomberoides. See Ichthyology. The same name has been applied to a genus of orthopterous insects. See Entomology.

BLETONISM, a supposed faculty of perceiving and indicating subterraneous springs and currents by sensation; so called from one Bleton, a Frenchman, who was reputed to possess such power.

BLIGHT, a disease incident to plants, and affecting them variously, the whole plant sometimes perishing by it, and sometimes only the leaves and blossoms, which are scorched and shrivelled up, whilst the rest remains green and flourishing.

BLIND,

General observations.

An epithet applied to a person deprived of the use of sight; or to one from whom light, colours, and all the variety of the visible creation, are intercepted by some natural deprivation or accidental disease.

There is no external sense or faculty which affords such an endless variety of perceptions as that of vision; nor of all losses that can be sustained is there one productive of so many disadvantages and evils as the want of that faculty. By no avenue of perception is knowledge so accessible, by none, in fact, does it flow so abundantly, as through the channel of this sense, which not only reveals external things in all their beauty, in all their changes, and in all their varie-

Blind. ties, but supplies those materials out of which the imagination creates new forms still more glorious; whilst the understanding traces the varied relations existing among the ideas thus received, and gives birth to a secondary and reflex class still more subtile and refined. To the blind man, however, the visible universe is totally annihilated; he is perfectly conscious of no space excepting that in which he stands, or to which his extremities can reach. Sound, indeed, gives him some ideas of distant objects; but these ideas are often obscure and indistinct; and although by them the notion of distance in general, or even of some particular distances, may be obtained, yet they never fill the mind with those vast and exalting conceptions of extension which are inspired by ocular perception. For although a clap of thunder or an explosion of ordnance may be distinctly heard after they have traversed an immense region of space, yet when the distance is uncommonly great it ceases to be indicated by sound; and hence the ideas of extension acquired by hearing are extremely confused and inadequate. But the living and comprehensive eye darts its instantaneous glance over expanded valleys, lofty mountains, sweeping rivers, and vast tracts of land or of ocean. It measures in an instant of time the mighty space from earth to heaven, or from one star to another. By the assistance of telescopes its horizon is almost indefinitely extended, its objects are greatly multiplied, and the sphere of its observation is prodigiously enlarged. By these means the imagination, habituated to vast impressions of distance, can not only recall them in their utmost extent with as much rapidity as they were at first imbibed, but can multiply them, and add one to another, till all boundaries, distances, and measures, are swallowed up in immensity. By profusely irradiating the face of things, and clothing objects in a robe of diversified splendour, nature at once invites the understanding to expatiate on that extensive and gorgeous theatre which she thus opens up, and gratifies the imagination with every possible exhibition of the sublime and the beautiful. The man of sight enjoys these unspeakable advantages, and beholds from afar the objects of his attention and curiosity. Taught by experience, he measures their relative distances; distinguishes their qualities; determines their situations, positions, and attitudes; traverses in security the space which divides them from him; stops at the point where they are placed; and either obtains them with ease, or immediately perceives the means by which the obstacles that intercept his passage to them may be surmounted. The blind, on the contrary, not only may be, but in reality are, during a considerable period, apprehensive of danger from every motion they make towards any object or place, because their contracted power of perception can give them no certain intelligence of the obstacles or hazards which may intervene.

Nor is this the worst of their case. All the various modes of delicate proportion, all the beautiful varieties of light and colours, whether exhibited in the works of nature or of art, are to them irretrievably lost. Dependent for every thing on the good offices of others, and from every object obnoxious to injury, which they are neither capacitated to perceive nor qualified to resist, they are, during the present state of being, rather to be considered as prisoners at large than citizens of nature. The sedentary life to which they are doomed relaxes the frame, and subjects them to all the disagreeable sensations which arise from dejection of spirits. Hence the most feeble exertions create lassitude and uneasiness, and the natural tone of the nervous system, destroyed by inactivity, exasperates and embitters every disagreeable impression. But even from their loss, however oppressive and irretrievable, they derive some advantages; not indeed adequate to recompense, but sufficient to alleviate, their misery. The attention of the mind, confined to those avenues of perception which it can command, is neither dissipated nor confounded by the multiplicity or rapid succession of surrounding objects. Its contemplations are more uniformly fixed upon itself and its own operations; and hence its perceptions of such external things as are contiguous and obvious to observation become more lively and exquisite, whilst even the instruments of corporeal sensation are more assiduously cultivated and improved; so that from them are derived notices and presages of approaching pleasure or impending danger, which entirely escape the attention of those who depend for security on the information of sight. A blind man, when walking swiftly, or running, is kindly and effectually checked by nature from rudely encountering such hard and extended objects as might hurt or bruise him. When he approaches bodies of this kind, he feels the atmosphere more sensibly resist his progress; and in proportion as his motion is accelerated, or his distance from the object diminished, the resistance is increased. He distinguishes the approach of his friend from afar by the sound of his steps, by his manner of breathing, and almost by every audible token which he can exhibit. Prepared for the dangers which he may encounter from the surface of the ground upon which he walks, his step is habitually firm and cautious. Hence he not only avoids those falls which might be occasioned by its less formidable inequalities, but from its general bias he collects some ideas how far his safety is immediately concerned; and although these conjectures may sometimes prove fallacious, yet they are generally so true as to preserve him from accidents not incurred by his own temerity. The rapid torrent and the deep cascade not only warn him to keep a proper distance, but inform him of the direction in which he is moving, and form a kind of audible beacons to regulate his course. In places to which he has been accustomed, he as it were recognises his latitude and longitude from every breath of varied fragrance wafted by the breeze, from every ascent or declivity in the road, from every natural or artificial sound that strikes his ear. Regulated by these and other analogous signs, the blind have not only been known to perform long and difficult journeys themselves, but even to conduct others through dark, tortuous, and dangerous paths, with the utmost security and exactness. Blind.

It were endless to recapitulate the various mechanical operations of which they are capable, from the nicety and accuracy of their touch. In some the tactile powers are said to have been so highly improved, as to perceive that texture and disposition of coloured surfaces by which some rays of light are reflected and others absorbed, and in this manner to distinguish colours.[1] But the testimonies to this fact still appear too vague and general to deserve implicit credit. We have known a person who had lost the use of his sight at an early period of infancy, and in the vivacity and delicacy of his sensations was not perhaps inferior to any one: this individual having often heard that others in his situation were capable of distinguishing colours by touch with the utmost exactness and promptitude; and being stimulated partly by curiosity to acquire a new train of ideas, if that acquisition were possible, but still more by incredulity respecting the fact alleged; tried

[1] De comite Mansfeldico cœco refert Keckermanus, solo tactu album a nigro discernere; de equo fusco vel alho, item de columba nigra vel cærulea, judicium ferre potuisse. (*Syst. Physic.* lib. iii. c. 16.)

Blind. repeated experiments, by touching the surfaces of different bodies, and examining whether any such diversities could be detected in them as might enable him to distinguish colours;—but nothing of the kind was he ever able to ascertain. Sometimes, indeed, he imagined that objects which had no colour, or, in other words, were black, had something different and peculiar in their surfaces; but this experiment did not universally hold; and his scepticism therefore still continued to prevail. That the acoustic perceptions of the blind are distinct and accurate, we may fairly conclude from the rapidity with which they ascertain the acuteness or gravity of different tones, as relative one to another, and from their exact discernment of the various kinds and modifications of sound and of sonorous objects, if the sounds themselves be in any degree significant of their causes.

It is owing to this vivacity and accuracy of the other senses, and the assiduous application of a comprehensive and attentive mind, that we are enabled to account for the rapid and astonishing progress which some of them have made, not only in those departments of literature which were most accessible to their understandings, but even in the most abstract, and, if we may be allowed the expression, occult sciences. What, for instance, can apparently be more remote from the conceptions of a blind man than the abstract relations and properties of space and quantity? Yet the attainments of Dr Saunderson in all the branches of mathematics are well known to the literary world since the publication of his works; and we have the testimony of Dr Guillié to the fact that the blind in general have a remarkable aptitude for the study of the exact sciences.[1]

When we reflect on the numberless advantages derived from the use of sight, and the immense importance of the information it conveys, both for the well-being of the body and the improvement of the mind, we are almost tempted to doubt the fidelity of the reports which have been published concerning such persons as, without the assistance of sight, have arrived at high degrees of eminence even in those sciences which would appear absolutely unattainable without the aid of this sense. It has, however, been demonstrated by Dr Reid, that blind men, by proper instruction, are capable of forming almost every idea, and attaining almost every truth, which can be impressed on the mind through the medium of light and colour, except the sensations of light and colour themselves. (*Inquiry into the Human Mind*, chap. vi. § 1, 2.) Yet there is one phenomenon of this kind which seems to have escaped the attention of that great philosopher, and of which no author either of this or any former period has been able to offer any satisfactory explanation, although it seems to merit the attention of philosophers. For, admitting that the blind can understand all the phenomena of light and colours, and that on these subjects they may extend their speculations even beyond the sphere of their instructions, and by the mere force of genius and application investigate the mechanical principles of optics from the data which they had previously obtained; yet it will be difficult to assign any reason why these objects should prove more interesting to a blind man than any other abstract truths whatsoever. By means of a retentive memory, it is possible for a blind man to tell that the sky is azure, that the sun, moon, and stars are bright, that the rose is red, the lily white or yellow, and the tulip variegated; by continually hearing these substantives and adjectives joined, he may be mechanically taught to join them in the same manner; but as he never had any sensation of colour, however accurately he may speak of coloured objects, his language must be like that of a parrot, without meaning and without ideas. Homer and Milton had been long acquainted with the visible world before they were afflicted with the calamity of blindness. They might, therefore, still retain the warm and pleasing impressions of what they had seen; their descriptions might be animated with all the enthusiasm which had originally fired their bosoms when the grand or delightful objects which they delineated were immediately beheld; and that enthusiasm might even be heightened by a bitter sense of their loss, and by the regret which a situation so dismal naturally inspired. But how shall we account for the same energy, the same transport of description, exhibited by those on whose minds visible objects were either never impressed, or must have been entirely obliterated? Blind.

Yet certain it is, however extraordinary the fact may appear, that the latter class of the blind experience such emotions, and depict them with astonishing accuracy and truth; that they seem to have a kind of imaginative feeling of external beauty, and to enter into accounts of natural scenery with a keener relish than those who enjoy the blessing of sight. To them light, and shadow, and colour in all its variegated modifications, are merely *voces et præterea nihil*; yet by the force of imagination, aided by the information supplied by the other senses, and by certain suggestions and relations of language, they are enabled, as it were, to approximate to ideas which it is impossible they should ever fully attain, and to form for themselves a set of notions adjusted in such a wonderful manner as to serve as links in the chain of association, and to guide them to the use of accurate expressions, in speaking or writing of things which to them are as if they were not. But the speculations into which these considerations would lead us are of too refined and subtile a nature to be prosecuted further in such an article as the present. Whoever thinks the subject of sufficient consequence to merit a nicer scrutiny, may consult the preface to *Blacklock's Poems* printed at Edinburgh 1754; or the account of his life and writings by the Rev. Mr Spence, prefixed to a quarto edition of his poems published at London in the year 1756; or the *Essai sur l'Instruction des Aveugles*, by Dr Guillié, a work which, from the opportunities of observation enjoyed by the author, is naturally of high authority on the subject of which it treats.

It has already been hinted that the blind are objects of compassion, because their sphere of action and observation is abridged; and this is certainly true. For what is human existence in its present state, when deprived of action, and to a certain extent of contemplation? Thus limited, all that remains is the information derived from form, or from sensitive and locomotive powers. But for these, unless directed to happier ends by superior faculties, few rational beings would, in our opinion, be grateful. The most important view, therefore, which can be entertained in the

[1] Si la privation de la vue peut, dans quelques circonstances, devenir un avantage, c'est dans l'étude des mathématiques. Les aveugles ont des dispositions naturelles pour cette science, à laquelle ils se livrent avec un goût décidé. Très-jeunes, ils apprennent facilement les opérations les plus compliquées de l'arithmétique, et, sans employer aucun des moyens dont les clair-voyans font usage pour la géométrie, ils ont une idée exacte et précise des figures; ce qui est prouvé par leur succès dans l'algèbre, la trigonométrie, et les autres branches subséquentes des mathématiques. Leur intelligence pour cette étude est tellement développée, que non seulement ils sont en état de suivre parfaitement les démonstrations faites sur le tableau, et de profiter des leçons publiques données par les maîtres les plus distingués (M. Biot, M. Francœur), mais même remporter, dans les Lycées, les premiers prix sur les clair-voyans. (*Essai sur l'Instruct. des Aveugles*, p. 159, 160.)

Blind. education of a person deprived of sight, is to redress as effectually as possible the natural disadvantages under which he lies; or, in other words, to enlarge as far as may be the sphere of his knowledge and activity. But this can only be done by the improvement of his intellectual, imaginative, or mechanical powers; and which of these ought to be most assiduously trained and cultivated, the genius of every individual can alone determine. Were men to judge of things by their intrinsic nature, less would be expected from the blind than from others. But, by some pernicious and unaccountable prejudice, people generally hope to find them either possessed of preternatural talents, or more attentive than others to those which they actually do possess: for it was not Rochester's opinion alone,

> That if one sense should be suppress'd,
> It but retires into the rest.

Hence it unluckily happens that blind men, when they do not gratify the extravagant expectations of the spectators, too frequently sink in the general estimation, and appear to be much less considerable and meritorious than they really are. This general diffidence of their powers at once deprives them both of the opportunity and the spirit to exert themselves; and they descend at last to that degree of insignificance in which the public estimate has fixed them. From the original dawning of reason and spirit, therefore, the parents and tutors of the blind ought to inculcate this maxim,—that it is their indispensable duty to excel, and that it is absolutely in their power to attain a high degree of eminence. To impress this notion on their minds, the first objects presented to their observation, and the first methods of improvement applied to their understanding, ought to be capable of being comprehended without difficulty by those internal powers and external senses which they possess. Not that improvement should be rendered quite easy to them, if such a plan were possible; for all difficulties which are not really or apparently insuperable heighten the charms and enhance the value of those acquisitions which they seem to retard. But care should be taken that these difficulties be not magnified or exaggerated by imagination; since the blind have naturally a painful sense of their own incapacity, and consequently a strong propensity to despondency continually working in their minds.

For this reason, parents and relations ought never to be too ready in offering their assistance to the blind in any office which they can perform, or in any acquisition which they can make for themselves, whether they are prompted by amusement or necessity. Let a blind boy be permitted to walk through the neighbourhood without a guide, not only though he should run some hazard, but even though he should suffer some pain. If he have a mechanical turn, let him not be denied the use of edge-tools; for it is better that he should lose a little blood, or even break a bone, than be perpetually confined to the same place, and thus debilitated in his frame, and depressed in his mind. Such a being can have no employment but that of feeling his own weakness, and becoming his own tormenter; or perhaps transferring to others a portion of the malignity and peevishness engendered by the natural, adventitious, or imaginary evils which he feels. Scars, fractures, and dislocations in his body, are trivial misfortunes compared with imbecility, timidity, or fretfulness of mind. Besides the pernicious effects of inactivity in relaxing the nerves, and consequently in depressing the spirits, nothing can be more productive of discontent, envy, jealousy, and every mean and malignant passion, than a painful impression of dependence on others, and of our insufficiency for our own happiness. This impression, which even in his most improved state will be but too deeply felt by every blind man, is redoubled by that utter incapacity of action superinduced by the officious humanity of those who would anticipate or supply all his wants, prevent all his motions, and do or procure every thing for him without his own interposition. It is the course of nature that blind people, as well as others, should survive their parents; and it may likewise happen to them to survive those who, by the ties of blood and nature, are more immediately interested in their happiness. But when they come to be dependent on the world, such exigencies as they themselves cannot meet will be but coldly and languidly supplied by strangers. If their expectations be high, their disappointments will be the more sensible; their desires will often be resisted, seldom fully gratified; and, even when their requests are granted, the concession will sometimes be so ungraceful as to deprive it of the character of kindness. For these reasons, we repeat, that, in the training of a blind man, it is infinitely better to direct than to supersede his own exertions. From the time he can move and feel, let him be taught to supply his own wants; to dress and to feed himself; to run from place to place, either for exercise or in pursuit of his own amusements or avocations. Blind.

In these excursions, however, it will be proper for the parent or tutor to superintend his motions at a distance, without seeming to watch over him. A vigilance too apparent may defeat its own object, and create, in a mind naturally jealous, a suspicion of its originating in some interested motive. But, on the other hand, when dangers are obvious and great, those who are intrusted with the care of the blind will find it neither necessary nor expedient to make their vigilance a secret. They ought then to acquaint their pupil that they are present with him, and to interpose for his preservation whenever his temerity renders it necessary. But objects of a nature less noxious, which may give him some pain without any permanent injury or mutilation, may with design be thrown in this way, provided, however, that the design be industriously concealed; for his own experience of their bad effects will prove a much more eloquent and sensible caution than the abstract and frigid counsels of any monitor whatever.

When the season of childish amusement has expired, and the impetuosity of animal spirits has abated, the tutor will probably observe, in the whole demeanour of his pupil, a more sensible degree of timidity and precaution, and his activity will then require to be stimulated rather than restrained. In this crisis, exercise will be found requisite to preserve health and facilitate the vital functions, as well as for the mere purpose of recreation; and, of all kinds of exercise, riding on horseback will be found by far the most eligible and advantageous. On such occasions, however, care must be taken that the horses employed be neither capricious nor unmanageable; for on the docility of the animal which he rides, not only the safety, but the confidence, of the blind will entirely depend. In these expeditions, whether long or short, his companion or attendant ought to be constantly with him; and the horse should either be taught to follow its guide, or be conducted by a leading rein. Next to this mode of exercise is walking. If the constitution of the blind boy be tolerably robust, let him be taught to encounter every vicissitude of weather which the human constitution can endure with impunity. And when the cold is so intense, or the elements so tempestuous, as to render air and exercise abroad impracticable, there are methods of exercise within doors, which, though not equally salutary, are still highly eligible. The dumb-bells, the bath-chair or spring board, and the common swing, have been particularly recommended for this purpose; and as each affords an agreeable exercitation, any of them may be had recourse to at pleasure.

Blind.

Education of the blind.

Institutions for the education of the blind have been established in different parts of Britain in the following order:—Liverpool, Edinburgh, Bristol, London, Norwich, Glasgow, York, Manchester, Newcastle-on-Tyne, Exeter, Aberdeen. There are three establishments in which the blind are received in Dublin, and one in Belfast. The oldest of these establishments with us date from about the beginning of this century; the majority of them from a few years only. We shall briefly describe the system practised in the Asylum for the Industrious Blind in Edinburgh,—an institution which, though in some respects inferior to that of Paris, is on the whole well calculated to serve as a model for others of a similar description.

This asylum was for many years the only one of the kind in Scotland; but latterly an institution of the same description has been formed at Glasgow, and is now conducted upon nearly the same plan. It was originally intended for men; and, during a period of twenty-eight years from its formation, no provision whatever was made for the employment or instruction of the blind of the other sex, who, from their greater helplessness, have still stronger claims to the charitable and humane consideration of the public. But about the year 1820 a female asylum was instituted under the care of the same directors, though in a separate house; and both branches of this interesting establishment are now conducted upon the same general plan, and with nearly equal success.

The leading feature of this plan is to combine industry with instruction, and alternately to find occupation for the hands and heads of those who are admitted into the asylum. Accordingly, the men and boys are employed in making baskets of all descriptions; in weaving cloth of cotton, linen, and hair; in rope-making in all its branches; in forming matrasses of straw, sea-grass, and hair, and in stuffing beds; in working door-mats, hearth-rugs, and other articles of this description; and, in general, in any occupation for which they have a taste, or in which they are likely to excel. The females, on the other hand, are employed in sewing, knitting, spinning, and other occupations peculiar or suited to their sex, especially in the different kinds of "plain and white seam," as it is called, which they execute with singular neatness. Stockings, shoes, snow-boots, table-mats, table-covers, shawls of all descriptions and colours, spensers, tippets, dresses for ladies and gentlemen, hair-mits, and such like articles, are also manufactured in the asylum. A great part of the knitted fancy work has, we understand, been invented by the mistress of the house; and such is the perfection to which this elegant branch of industry has been carried, that its products are said to have found their way to all parts of the world.

Blind.

France has done much towards the education of the blind, which indeed has engrossed a large share of attention in that country; but although the methods employed are in some respects superior in point of scientific adaptation, it may, nevertheless, be doubted whether any institution in the neighbouring kingdom be upon a more efficient footing than that in Edinburgh, which owes not only its existence, but the success which has attended its endeavours, to the spontaneous and benevolent zeal of enlightened individuals. Various opinions have been expressed respecting the French method of teaching the blind to read by means of letters in relief,—a very ingenious though by no means a recent invention.[1] It has been said, for example, that angular letters are preferable to circular ones, as being more easily felt; and Mr Gall of Edinburgh has constructed an alphabet of this kind on the French plan, whilst others have been making trial of a variety of shapes and forms with a view to the same object. But no device of this kind has hitherto been patronised by the directors of the Edinburgh institution; nor, as far as we know, has any one yet been proposed which is in all respects calculated to answer the end proposed. From what has been done, however, for enabling the blind to feel a written language, it seems practicable, by some analogous method, to teach them both to read and write; and we are inclined to hope that such a method, combining distinctness with simplicity and cheapness, will in time be discovered.

In the Edinburgh institution the men and women are taught to read and write by means of what is called the "string alphabet." This is formed by so knotting a cord, ribbon, or the like, that the protuberances thus made upon it may, by their shape, size, and situation, denote the elements of language. The letters of this alphabet are distributed into seven classes, which are distinguished by certain knots or marks; and each class comprehends four letters, excepting the last, which includes only two. The first or A class is distinguished by a large round knot; the second or E class, by a knot projecting from the line; the third or I class, by a series of links, vulgarly called the "drummer's plait;" the fourth or M class, by a single noose; the fifth or Q class, by a noose with a line drawn through it; the sixth or U class, by a noose with a net-knot cast on it; the seventh or Y class, by a twisted noose. The first letter of each class is denoted by the simple characteristic of its respective class; the second by the characteristic and a common knot close to it; the third by the characteristic and a common knot half an inch from it;

---

[1] The first attempt of this kind appears to have consisted in a modification of the Illyrian or Sclavonian alphabet, which was doubtless preferred on account of the square form of the letters; but on trial it was found to possess no advantage over the common characters, and to have disadvantages peculiar to itself. (Fournier, *Manuel Typographique*, tome ii. p. 226, No. 68, 1766.) Movable letters on small tablets of wood were next tried; but after a time this expedient was also abandoned, as not suited for the instruction of the blind, though singularly well adapted for teaching children who see to read. In fact, it was by means of similar letters that Usher, afterwards archbishop of Armagh, was taught to read by his two aunts, who were both blind. (*Biographia Britannica*, *voce* Usher; London, 1773). In the sixteenth century letters were engraved in wood for the instruction of the blind;—these, however, were not in relief, but cut out in the ordinary way of engraving;—the fingers could with difficulty be employed in ascertaining their configuration;—when used in printing, the letters remained white, whilst the rest of the space was blackened;—and hence they had none of the advantages which belong to letters in relief, and which are essential in the instruction of the blind. (Francesco Lucas, *Arte de Escrivir*, Madrid, 1580, 4to.) This method was reproduced with some modifications in 1575, by Rampazzetto, an Italian; but with no better success. (*Essemplare di più sorti di Lettere* di M. Gio Francesco Cresci, Milanese, Scrittore en Venetia; 1575, 4to.) In 1640 a writing-master of Paris, called Pierre Moreau, caused movable characters to be cast in lead for the use of the blind; but, discouraged by the difficulties he met with, or not choosing to incur the expense to which the prosecution of the scheme would have subjected him, he abandoned it, and applied himself to the formation of matrices for a new variety of letter, which still bears his name in French typography. A simpler and more ingenious method than any of these consisted in forming letters by means of pins stuck into large pincushions, leaving out only the heads, which of course were easily felt, and rendered the shape of the letters quite distinct as well as palpable, while the arrangement could be altered at pleasure, and with extreme facility. By this natural and easy plan the celebrated Mademoiselle Paradis learned to read. Various other modes were also tried; letters in wood were again had recourse to, and again dropped; and no method secured general approbation till 1783, when letters in relief, that is, letters raised, or as it were embossed on paper, were first invented, and, being gradually improved, were afterwards employed in the instruction of the blind in France. Nor has this invention as yet been superseded by any thing that seems better adapted to the purpose.

Blind. and the fourth by the characteristic and a common knot an inch from it. Thus, A is expressed by a large round knot; B by a large round knot, with a common knot close to it; C by a large round knot, and a common knot half an inch from it; and D by a large round knot, and a common knot an inch from it; and so in the case of the other classes. This alphabet was invented by Robert Milne and David Macbeath, both at one time inmates of the asylum, and it is found by experience to answer the purpose for which it was intended, as by means of it the blind can communicate with their friends and with one another.

Robert Milne, one of the persons above named, also improved the arithmetical board. An instrument of this kind had been invented by Dr Saunderson, and afterwards modified by Dr Moyes; but the board used in the asylum is considered as superior to it in several respects, and has lately undergone a further improvement by the substitution of metal for wood; in consequence of which it has been rendered both cheaper and more correct than before. By means of this instrument both men and women are taught figuring, and may be carried to any extent in arithmetical acquirement. Two small square pins with knobs represent the ten digits.[1]

The blind are taught geography, both ancient and modern, by means of globes and boards constructed solely for their use; astronomy, by means of an orrery and celestial maps similarly adapted; and mathematics, on a board of analogous construction. In all these branches of science the progress they make is considerable, and, with reference to their peculiar situation, astonishing. As the plan of the globes and boards is exceedingly simple, a few words on each will suffice. From a plan submitted to him, the present master constructed two globes, one thirty and the other thirty-six inches in diameter. Having described the meridians and parallels of latitude, and drawn the boundary lines of countries, and divisions of all kinds, he glued on twine or cord on such lines as are continuous, employing shorter pieces to indicate rivers, and pins to denote towns: the portions representing land are covered with fine sand; the rivers and seas are left smooth; the meridian circle, which is of iron, is so deeply marked as to render the divisions easily felt; and the equator is indicated by small pins. The globes, thus prepared and adapted, have been found by experience completely to answer the purposes of instruction. With regard to the maps, again, they are pasted on square boards, and have cord glued on the boundary lines, in precisely the same manner as the globes.[2] The orrery has brass hoops or rings to represent the orbits of the planets, which are indicated by balls or spheres of proper relative dimensions, and slide at pleasure along the rings or orbits; the ecliptic, or the outer edge of the circular board, is marked with the degrees of the circle and the days of the month in such a manner as to be felt; and the signs of the zodiac are raised figures, also placed on the edge. The celestial maps consist of square and oblong boards, on which is glued Bristol paper, cut into the figure of the sign or constellation which it is intended to represent, after which steel knobs of different sizes are driven in to indicate the different magnitudes of the stars, while small knobs on the sides of the board denote the degrees. The mathematical board is a square of fourteen inches, full of small holes, with a few pins fitted to them, so as to represent certain letters of the alphabet; while Blind. with fine cord or twine extended from the angular points are formed the lines of the figure or diagram, whatever it may be. The globes and boards for geography, as well as the orrery, celestial maps, and mathematical board, were invented in 1824, and are used in no other institution excepting that of Glasgow, and that of Boston in North America, to each of which a set of these instruments was transmitted by order of the directors of the Edinburgh Asylum. In as far as we are able to judge, these latter instruments seem superior to those employed in the Parisian institution; at all events they are simpler, which is a great advantage; and with regard to the mathematical board, the method of representing the diagrams appears to be by far the best that has yet been employed.

The inmates of this establishment are also taught to play on the violin and piano-forte. They read the music from boards constructed for their use, but by whom invented we have not learned. The game of draughts is a favourite amusement with them. It is played on a board of the common kind, but the alternate squares are covered with sand, and in each there is a small hole fitted to receive a pin, attached to the piece, which is thus retained in the position in which it is placed.

The greater part of the inmates of this institution consists of persons who originally lost their sight by disease or accident; and there are but few who have been blind from their birth. At the same time, it has been remarked that when one child in a family is born blind, those that follow it are also generally born blind. There are two or three instances of this in the asylum; and we know several others without the walls of the institution. This succession of blindness is probably to be referred to the force of imagination; and, in fact, the mother of two blind children being questioned on the subject, stated her belief that the second instance was occasioned by her continually looking on and thinking of her sightless child.

Results. The experience acquired in the institution confirms the general observation which we made at the outset, that the loss of one faculty, especially sight, is almost always accompanied by a compensatory and counterbalancing improvement in the other senses and faculties. This undoubtedly arises, not from any original superiority in the senses or faculties which remain, but from a closer attention to their indications, and above all from incessant application. The sense of touch, in particular, is signally improved, and, as it were, quickened in blind persons, who have no other means of discovering the size and figure of the bodies presented to them. With regard to the statement, however, which has sometimes been made, that they can distinguish colours by touch, we may mention that no instance of such extreme delicacy of touch has occurred in the experience of the Edinburgh institution. Memory, like touch, is also improved by constant use and application; and this holds equally true in all cases, though it is more signally exemplified in the case of the blind, who depend so much on this faculty. It has been thought that the memories of the blind are greatly assisted by the exclusion of external objects, which from their multiplicity tend to distract the attention; but as darkness magnifies dangers, which consequently engross the thoughts and excite continual apprehensions, it may reasonably be doubted whether the attention of the blind is

[1] For an account of the method employed in the Royal Institution of Paris, see Dr Guillié's *Essai sur l'Instruction des Aveugles*, p. 159. In Paris, as in Edinburgh, Saunderson's table has been abandoned as operose and inconvenient.

[2] In the Parisian institution improvement has been carried a step further; fine iron wire covered after the fashion of milliners is used instead of cord for the divisions, as well as the meridians and parallels of latitude; whilst towns and islands are represented by hemispherically-headed nails of different sizes; and over the whole blank paper is pasted, so as in fact to form a skeleton map in relief. (*Guillié*, p. 147, 149.)

Blind. not at times as liable to be disturbed as that of those who possess the blessing of sight, and receive impressions from the external world; and hence it is to application chiefly that the improvement of this faculty in the case of the blind ought to be ascribed.

The same observation holds true in regard to those signs and indications which persons who see neglect because they are not necessary to be attended to, but which are of great importance to the blind, and are consequently carefully attended to by them. Hence they can discover by the voice whether a person be tall or short, agreeable or disagreeable, and also form some judgment of the passions and affections of the mind. They have even in some cases attempted, from such indications, to describe the external form and beauty of a person. They know the steps of their friends and companions even at a distance. Breathing and smell also afford indications. In hearing a sermon they can tell by the sound of the preacher's voice whether he uses notes; and currents of air, or different modifications of atmospherical pressure, enable them to discover when they approach any object or building. Their curiosity is so intense that at any risk it must be gratified; and as they are often not aware of the danger to which they expose themselves, they generally attain their object. It is a remarkable fact, that a person born blind never dreams that he *sees* the object of his dreams.

The blind have been made to communicate with the deaf and dumb by means of the finger alphabet; the former, of course, appealing to the *sight* of the latter, and the latter forming the alphabetical characters *palpably* on the fingers of the former. An attempt was also made by the deaf and dumb to discover what was said by the blind from the varying configuration of their lips in speaking; but it did not succeed to any extent, and was abandoned, more especially as it could be employed by only one of the parties. In France the means of communication between these two classes of unfortunates have been improved by the invention of a set of pantomimic signs, representing not letters, but words or ideas. These are formed by means of the arms, which being extended somewhat in the manner of a telegraph, are made, by each change of position, to represent a word or idea; and when the blind communicate in this way with the deaf and dumb, their arms are placed in contact, and they go through the strange but ingenious pantomime together in a manner equally grotesque and amusing.

Parisian institution. The experience acquired in the Parisian institution is substantially in accordance with what has been stated as the results of continued observation in the Edinburgh asylum. Dr Guillié is decidedly of opinion that the blind have no natural superiority in any sense or faculty over those who possess all their faculties in an ordinary state of perfection. " L'adresse qu'on remarque dans les aveugles pour le toucher," says he, " et l'aptitude des sourds-muets à saisir tous les traits de la physionomie, résultent de la nécessité où ils sont, les uns, de se servir presque continuellement du tact pour suppléer à la vue qui leur manque, et les autres, d'employer la vue pour remplacer l'ouïe et la parole: l'organe n'en est pas moins en tout semblable à celui des clair-voyans; et si l'aveugle-né opéré par Cheselden ne reconnaissait plus par le toucher, après l'extraction de la cataracte, les objets comme il le faisait auparavant, ce n'est pas qu'il eût perdu, en recevant la vue, la faculté de toucher, mais seulement, parce qu'il ne l'employait plus que comme sens auxiliaire et correctif de la vue." P. 32, 33. In this opinion the Abbé Sicard, Dr Guillié's distinguished colleague, completely coincides.

" The memory of the blind is prodigious" This fact has been exemplified in Paris as well as in Edinburgh and everywhere else; how to account for it is another question. In man there is a memory of sensation and a memory of intelligence: the one recalling his merely physical perceptions; and the other his reflections, judgments, reasonings, speculations, and moral sentiments. Now it is principally with the latter description of memory that the blind are eminently provided; and although they are deprived of the means which persons having the use of sight possess for forming an artificial kind of mnemonics, it is probable that they construct an internal scheme for their own use, and of still superior efficacy. Such at least is the opinion of Dr Guillié; and it appears to be well founded. Helvetius has remarked (*De l'Esprit*, chap. iii. disc. 3), that a great memory is a phenomenon of order; that it is almost entirely factitious; and that among men well organised, the great inequality of memory is less the effect of unequal perfection in the organ or faculty which produces it, than of unequal attention in cultivating it. But the blind are in general eminently distinguished for the spirit of order, referred to by the French philosopher as the basis of a great memory; and as the faculty in question depends mainly on association, of which natural arrangement or classification is the very essence, it must of course be greatly strengthened in minds which are animated by the spirit of order, and have a tendency to arrange their ideas in a strictly logical sequence. Blind.

Another peculiarity of the blind is great fecundity of imagination; united in some with a facility in analyzing and recombining their ideas, to which their extraordinary progress in the exact sciences is to be ascribed. Of the former quality, Homer, Milton, Delille, and many others might be cited as examples; of the latter we shall give two instances in the words of Dr Guillié. " Le premier est Paingeon, qui, par l'esprit de l'ordre dont il est doué, a acquis des connaissances transcendantes en mathématiques, et après avoir remporté, en 1806, tous les premiers prix au concours général des quatre Lycées de Paris, fut nommé, par le Grand Maître de l'Université, professeur de mathématiques au Lycée d'Angers: l'autre est J. Delille, aujourd'hui pensionnaire des Quinze-Vingts, qui a porté très-loin la métaphysique de la langage Française; un aplomb parfait, une précision admirable dans ses definitions, caractérisent surtout ce sujet que nous nous énorgueillissons d'avoir formé." Both were educated under Dr Guillié, at the Royal Institution for the instruction of the blind.

On the subject of the moral condition of the blind Dr Guillié has stated many curious and interesting particulars. They are generally deficient in modesty or shame. " La pudeur, qui est une des grâces de la jeunesse, est presque pour eux un être imaginaire, quoiqu'ils aient une sorte de timidité qui tient peut-être plus, il est vrai, de crainte que de la honte, mais qui augmente beaucoup leur embarras dans certaines circonstances." They are, it is said, for the most part without sensibility and without gratitude; irritable, suspicious, vindictive, implacable. Their situation obliges them to be on their guard against all the world; the consciousness of their own deficiency, and the disadvantages under which it places them, render them suspicious as well as selfish; and, by an easy, and we had almost said natural transition, they come to arrange in the same category their benefactors and their enemies. " Commes de toutes les démonstrations extérieures, qui rêveillent en nous la commisération et les idées de la douleur, les aveugles ne sont affectés que par la plainte," says Diderot, " je les soupçonne, en general, d'inhumanité. Quelle différence y a-t-il, pour un aveugle, entre un homme qui urine et un homme qui, sans se plaindre, verse son sang? Nous-mêmes, ne cessons-nous pas de compatir, lorsque la distance, ou la petitesse des objets, produit sur nous le même effet que la privation de la vue chez les aveugles."

Blind. (*Lettres sur les Aveugles.*) This is too strongly stated; but the principle in human nature, on which the striking observation of Diderot is founded, would lead us to anticipate, at least in part, the moral results to which we have alluded. It has been alleged that the blind have a tendency towards atheism; but this is denied by Dr Guillié, who, however, qualifies his contradiction by a very lamentable admission: "Néanmoins, je ne les justifierai pas entièrement du reproche d'impiété qu'on leur a fait avec quelque fondement;" and he adds, "la conscience enfin n'a pas sur leurs actions l'influence qu'elle a sur nous." But as these observations are grounded on a partial experience, we hope they have no application to the blind of this country, amongst whom sounder principles and better feelings will always, we trust, prevail; nor will they ever lose a sense of dependence on that Being, whose existence they have only to stretch forth their hands to discover, and who has opened the eye of humanity to compassionate, and the hand of charity to relieve, their wants.

Remarkable blind persons.

History has preserved sundry particulars of blind persons, who, of themselves, acquired great knowledge before there existed any regular method of instruction applicable to their case. The number of these is considerable; so much so, indeed, that any accurate enumeration would not only be a task of great difficulty in itself, but would also far exceed the limits prescribed to this article. It may not be uninteresting, however, to signalize a few of those who have made the greatest figure in science and in art.

The number of blind appears to have been very considerable in Asia and Italy in the time of the Romans. This is proved by the great number of physicians who at the epoch in question wrote on ocular diseases; but what mode of instruction, or whether any at all, was employed in those times, we have not learned. Diogenes Laertius and Thrasylus relate (Diog. Laert. lib. ix., Vossius, *De Philosophia*) that several philosophers voluntarily deprived themselves of sight in order to pursue their contemplations with less interruption; and, amongst those who inflicted on themselves this deprivation, is cited Democritus of Abdera. But it is scarcely probable that this philosopher, the companion of the gymnosophists of India, a man who laughed at every thing, and whom his countrymen wished Hippocrates to cure of madness, because he believed that all things were as they ought to be, depending on chance and the fortuitous aggregations of atoms, should have put out his eyes in order to scoff philosophically, when he might have indulged his humour to so much better purpose with the use of his sight. Besides, putting out the eyes was next to crucifixion, one of the most ignominious punishments inflicted by the laws of ancient times, and as such was reserved only for great criminals. It may therefore be doubted whether the laughing philosopher of Abdera would, on a mere hypothesis, treat himself like a felon: and the words of Cicero, "Democritus impediri etiam animi aciem aspectu oculorum arbitrabatur (*Tuscul. Disp.* v. 39), which have been often quoted, seem rather to express a general opinion than to state a particular fact, or warrant the inference that the philosopher had deprived himself of sight because he thought that the penetration of the mental was impeded by the vision of the natural eye.

Diodatus, Cicero's master in philosophy, applied himself to study with more assiduity than ever, after he had lost his sight; and, what is still more remarkable, he taught geometry with so much precision, that his disciples found no difficulty in comprehending how to trace the most complicated figures from his instructions. (Cicero, *ubi supra*; Zahn, *Specul. Physico-Math. Hist.* tome iii. c. 6.) Cornelius Aufidius, a Roman citizen, who had lost his sight in his youth, distinguished himself in the study of elegant literature, and wrote a Greek history. (Zahn, *Sens. Ext. Mirab.* § 2.) Eusebius the Asiatic became blind at five years of age. He acquired vast knowledge and profound erudition, and taught with the utmost facility as well as success. (Cassiodorus *De Inst. Div. Litter.* c. 5.) St Jerome has left an account of Dydimus of Alexandria, his master, of whom he speaks with great respect. This blind man, who had lost his sight at the same age with Eusebius, flourished in the fourth century. Ruffinus, Paladus, Isidorus, and several other celebrated men, were his disciples. He acquired great knowledge by having the sacred and profane authors read to him; he was one of the ablest mathematicians of his time; and he applied himself especially to theology, for which he had a decided taste. He composed several works, the principal of which is *A Treatise on the Holy Spirit*, translated into Latin by St Jerome. Dydimus was pious as well as learned: nevertheless, his attachment to the opinions of Origen, on whose books he had commented, caused his works to be condemned after his death by the council of Lateran. St Athanasius and St Antony had the greatest esteem for him. Dydimus died A. D. 398, at the age of eighty-five. (Hieronymus *De Viris Illustr.* c. 109; Socrates, lib. iv. c. 25; Ruffinus, lib. ii. c. 7.)

Nicaise of Malignes flourished in the fifteenth century, and enjoyed great reputation for the extent of his learning. Blind from the age of three years, he nevertheless made great advances in science, and taught publicly, in the university of Cologne, both the civil and canon law, citing from memory long passages which he had never seen, *quos nunquam viderat.* Having been elected doctor of Louvain, the pope granted a dispensation for his admission to priests' orders; after which he employed the rest of his life in preaching, and died at Cologne in 1492. (Urithème et Valère, *Bibliothèque des Ecrivains des Pays-Bas.*) James Shegkius, born at Shorndorf, in the duchy of Wirtemburg, taught philosophy and medicine with great success at Tubingen for about thirteen years. Having early become blind, he was so little sensible of the loss of sight that he refused to allow himself to be couched by an oculist, who offered to restore vision—in order, as he said, not to be obliged to see many things which appeared odious or ridiculous. He died at Tubingen in 1587, leaving several treatises on different points of philosophy, medicine, and controversy. (Zahn, *Visus Im. Dep. et Cæcit. Ex. Mir.* p. 114.) John Fernand, born in Belgium, was the son of a Spaniard, and blind from his birth. His father was very poor; but he surmounted the obstacles both of poverty and blindness, and became a poet, logician, philosopher, and musician. He composed from memory several pieces, which are considered excellent of their kind. (Zahn, *ubi supra.*) Ascanius Pedianus the historian lived several years after the loss of his sight, and wrote treatises on grammar, which exhibit no trace either of his age or infirmity. (*Fulgosus*, lib. viii. c. 7.)

Uldaric Schomberg, born in Germany towards the commencement of the seventeenth century, lost his sight by the small-pox at the age of three; but as he grew up he applied himself to the study of the belles-lettres, which he afterwards professed with credit at Altorf, at Leipsic, and at Hamburg. (C. Harknocks, *Alt und Neu Preussen*, 1684.) Bourchenu de Valbonais, born at Grenoble in 1651, became blind when very young, soon after the naval combat at Solbaye, where he had been present. But this accident did not prevent him from publishing the *History of Dauphiné*, in two volumes folio. He had made profound researches into the history of his province, and, besides the work just mentioned, published a *Nobiliaire* of Dauphiné. (*Feller*, vol. ii.) Of Dr Nicolas Saunderson, Lucasian

Blind. Professor of Mathematics in the University of Cambridge, and one of the most remarkable men of his time, some account will be found under the proper head. He was born in 1682, at a small town in the county of York, and died at Cambridge in 1739, at the age of fifty-six. He invented a table, which has since been greatly improved, for teaching arithmetic palpably to the blind. A notice of Dr Blacklock will be found under the biography of that individual. Dr Henry Moyes professed the Newtonian philosophy, which he taught with considerable success as an itinerant lecturer. He was also a good chemist, a respectable mathematician, and a tolerable musician.

M. Phefel of Colmar, who lost his sight when very young, in consequence of a violent ophthalmia, composed a great deal of poetry (6 vols. 8vo, Colmar, 1791), consisting chiefly of fables, some of which have been translated into French by M. Degerando. He was privy counsellor to the margrave of Baden; and established at Colmar a military school or academy, where children of the best families were sent to be educated. Among the pupils of this learned blind man may be mentioned Prince Schwartzemberg, Prince Eisemburg, and M. Heilman, lately pensionary of the Quinze-Vingts. He died at Colmar in 1809. Weissemburg of Manheim became blind at the age of seven. He wrote perfectly, and read with characters which he had imagined for his own use. He was an excellent geographer, and composed maps and globes, which he employed both in studying and teaching this science. He was the inventor of an arithmetical table, differing but little from that of Saunderson. (*Journal de Paris*, April, 1784.)

The blind man of Puiseaux must be known to all who have read Diderot's celebrated *Lettres sur les Aveugles*. He was the son of a professor of philosophy in the university of Paris, and he had attended with advantage courses of chemistry and botany at the Jardin du Roi. After having dissipated a part of his fortune he retired to Puiseaux, where he established a distillery, the products of which he came regularly once a year to Paris to dispose of. There was originality in every thing that he did. His custom was to sleep during the day, and to rise in the evening; he worked all night, "because," as he himself said, "he was not then disturbed by anybody." His wife, when she rose in the morning, used to find every thing perfectly arranged. He spoke very sensibly of the qualities and defects of the organ in which he was deficient, and answered questions put to him with much justness and discrimination. Being interrogated as to the idea he formed of a mirror, he replied, "C'est une machine qui met les choses en relief loin d'elles-mêmes, si elles se trouvent placées convenablement par rapport à elle. C'est comme ma main qu'il ne faut pas que je pose à côté d'un objet pour le sentir." To Diderot, who visited him at Puiseaux, he put some very singular questions on the transparence of glass, colours, and such like matters. He asked if naturalists were the only persons who saw with the microscope, and if astronomers were the only persons who saw with the telescope; if the machine which magnified objects was greater than that which diminished them; if that which brought them near was shorter than that which removed them to a distance. He believed that astronomers had eyes of different conformation from those of other men, and that a man could not devote himself to the study of a particular science without having eyes specially adapted for the purpose. "The eye," said he, "is an organ upon which the air ought to produce the same effect as my cane does upon my hand." He possessed the memory of sounds to a surprising degree, and recognised by the voice those whom he had only heard speak once. He could tell if he was in a thoroughfare or in a cul-de-sac, in a large or in a small place. He estimated the proximity of fire by the degree of heat; the comparative fulness of vessels by the sound of the liquor in falling; and the neighbourhood of bodies by the action of the air on his face. Being asked on one occasion if he would not be very well pleased to have eyes, he replied, "Si la curiosité ne me dominait pas, j'aimerais bien autant avoir de longs bras: il me semble que mes mains m'instruiraient mieux de ce qui se passe dans la lune que vos yeux ou vos telescopes; et puis les yeux cessent plutôt de voir que les mains de toucher. Il vaudrait donc bien autant qu'on perfectionnât en moi l'organe que j'ai, que de m'accorder celui qui me manque." He employed characters in relief in order to teach his son to read, and the latter never had any other master than his father. Blind.

M. Huber of Geneva, an excellent naturalist, and author of the best treatise extant on bees and ants, was blind from his earliest infancy. In reading the descriptions of these insects, we can scarcely persuade ourselves that they are not the production of a singularly clear-sighted man, well versed in this branch of natural history. In executing his great work, however, M. Huber had no other assistance than what he derived from his domestic, who mentioned to him the colour of the insects; and then he ascertained their form and size by touch, with the same facility as he would have recognised them by their humming when flying in the air. This laborious writer has also published a valuable work on education.

Francis Lesueur, born of very poor parents, at Lyons, on the 5th of August 1766, lost his sight when only six weeks old. He went to Paris in 1778, and was begging at the gate of a church, when M. Haüy, discovering in the young mendicant some inclination to study, received him, and undertook the task of instructing him, at the same time promising him a sum equal to that which he had collected in alms. Lesueur began to study in October 1784. Six months after, he was able to read, to compose with characters in relief, to print; and in less than two years he had learned the French language, geography, and music, which he understood very well. His intelligence and penetration were indeed surprising, and he was among the blind what Massieu has since been among the deaf and dumb. He was successively repeater to his comrades, head of the printing and economy of the institution for the blind, and pensionary of the Quinze-Vingts. It is painful to add, that he proved unthankful to his benefactor and master, to whom he owed every thing; and that by his conduct he merited the reproach of ingratitude, a vice which, with some reason, has been charged against the blind generally.

Avisse, born at Paris, was one of the most distinguished élèves of the institution. His father, who kept furnished lodgings in the Rue Guénégaud, intended him for the sea; and he embarked when very young on board a vessel fitted out for the slave-trade, in the capacity of secretary or clerk to the captain; but he was struck by a *coup de vent* on the coast of Africa, and lost his sight from the violent inflammation which ensued. On his return his parents procured his admission into the institution for the blind, where, in a few years, he became professor of grammar and logic. He produced a comedy in verse, in one act, entitled, *La Ruse d'Aveugle*, which was performed on the 2d Nivose, year 5; a scene, also in verse, entitled *L'Atelier des Aveugles-travailleurs;* and several other pieces, which were all printed in one volume 12mo. in the year 1803. He died before he had completed his thirty-first year, at the very time when the high hopes entertained of him were on the point of being realized.

Nor have the blind been less distinguished in the practice of the arts than in science and literature. Many instances of their eminence in this respect may be mentioned. Indeed, the want of sight seems little or no impediment to manual dexterity. Stengel mentions a young

Blind. cabinet-maker of Ingolstadt, who, having lost his sight by an explosion of gun-powder, amused himself by constructing pepper-mills, which he made without the use of any other instrument than a common knife, and executed with so much exactness and elegance that they were thought deserving of a place in the gallery of curiosities at Munich, where they may still be seen. (Laurentius Stengelius *De Monstris*, c. 16.) Sir Kenelm Digby has stated several extraordinary particulars of a preceptor of his son, who was so completely blind that he could not distinguish the light of noonday from midnight. He surpassed in skill the ablest players at chess; at long distances he shot arrows with such precision as almost never to miss the mark; he constantly went abroad without a guide, and frequented most of the public promenades; he regularly took his place at table, and ate with such dexterity that it was impossible to perceive he was blind; when any one spoke to him for the first time, he was able to tell with certainty his stature and the form of his body; and when his pupils recited in his presence, he knew in what situation and attitude they were. (Digbæus *De Nat. Corpor.* c. 28.) Aldrovandus mentions (*Hist. Monstr.*) a butcher of Boulogne, who estimated by touch the weight of the animal he was about to kill. M. de Piles saw in Italy a blind man, a native of Cambassy in Tuscany, who was a very good designer. M. de Piles met him in the Justiniani Palace, where he was modelling in wax a statue of Minerva. By means of touch, he had seized with precision the form and proportions of the original. The duke of Bracciano, who had seen him working, doubted whether he was completely blind; and, in order to put the matter to the test, he caused the artist to take his portrait in a dark cave. It proved a striking likeness. Some, however, objecting that the duke's beard, which was of patriarchal amplitude, had helped the artist to recognise him, the latter offered to execute a portrait of one of the duke's daughters, which he accordingly did, and it also proved an excellent likeness. "J'ai vû," says M. de Piles, "sortis des mains de cet illustre aveugle les portraits du feu roi d'Angleterre, Charles I., celui du pape Urbain VIII., et en France, le portrait de M. Hesselin, tous parfaitement exécutés." (*Cours de Peinture*, p 260, 1766.) "Nous avons vû, dès nos jours," says Dr Guillié, to whom we are indebted for the particulars of the more distinguished blind, "M. Buret, l'un des plus habiles sculpteurs de l'académie, devenu aveugle, à l'âge de vingt-cinq ans, par suite de la petite vérole, ne pas cesser pour cela de travailler, comme le faisait l'aveugle de Cambassy." (*Essai sur l'Instruction des Aveugles*, p. 94, Paris, 1817.)

Giovanni Gambasio of Volterra lost his sight at the age of twenty, and remained ten years in this state, ignorant of even the elements of sculpture. All of a sudden, however, "the desire of making a statue came upon him;" and having handled in every way a marble figure representing Cosmo de' Medici, he formed one of clay, so extremely like that it astonished all who saw it. His talent for statuary now developed itself to such a degree, that Prince Ferdinand, grand duke of Tuscany, sent him to Rome to model the statue of Pope Urban VIII. which he also rendered a striking likeness of the original. He also executed many others with equal success. (Aldrovandus, *Hist. Monstr.*) A Dutch organist, blind from his early youth, became very skilful in his profession; he also acquired the habit of distinguishing by touch the different kinds of money, and even, it is said, the primary colours. He was a first-rate card-player; for in dealing he knew the cards which he gave to others as well as those which he kept for himself. (Lecat, *Traités des Sens*, p. 11.) Chauvet, born blind, was for several years organist of Notre-Dame-de-Bonne-Nouvelle at Paris. Mademoiselle Paradis of Vienna, who had lost her sight when two years old, formed the delight of the spiritual concerts at Paris in the year 1784. This lady, who had great talents for musical composition, invented a method of writing whatever she composed, by figuring the concords. She began at first by tracing them on cards pricked with needles; but this first essay proving unsatisfactory, she fell upon another method, which, however, has not been explained,—a circumstance we regret the more, since it has been described as at once certain and of easy execution. Holman, the blind traveller, being still alive, can scarcely with propriety be made the subject of a notice in this place. Blind.

This catalogue might easily be extended; but enough has been said, and a sufficient number of facts accumulated, to show what the blind are really capable of. There seems, in truth, to be a sort of compensating power, alike subtile in its resources and refined in its operation, by which a multitude of latent faculties and unheeded perceptions are called into activity to supply the want of one great inlet of knowledge, and which, taken in the aggregate, and fully developed, appear almost sufficient to fill up the blank which has been left by nature or produced by disease in the catalogue of human organs. Hence there are few things practicable by persons possessed of sight which have not been done by those who want it; whilst in regard to several the balance of advantage is clearly in favour of the blind. This is at once a wise and beneficent provision of nature; in perfect harmony with the whole economy of providence in the structure of the body as well as of the mind of man; and singularly illustrative of that foresight which has provided, with such benevolent care, for the casualties as well as the wants to which we are exposed in the present state of existence. Had the case been otherwise every loss would have been irreparable, and the smallest deprivation would have driven us to despair. (J. B—E.)

The number of blind persons in Great Britain has been variously estimated; by the most recent authorities it is computed at 25,000. Of these the great majority belong to the poorer classes, and consequently possess few facilities for education or self-improvement. A good deal has of late years been attempted with a view to ameliorate their condition; but very much still remains to be done. Many causes conspire to retard and obstruct the kindly efforts of English philanthropists in their behalf, and none more than the tenacious rivalry of self-asserting system-mongers. While the public is engaged in deciding upon the respective merits of these "systems," it forgets the beautiful maxim "bis dat, qui cito dat;" and the objects of their benevolence meanwhile pine away in neglected helplessness. It is impossible here to discuss or even to enumerate all the methods that have been devised for the education of the blind; we shall therefore confine ourselves to those that, by their popularity or their intrinsic worth, recommend themselves most strongly to our consideration. Their object—the teaching of the blind to read, and in this way developing the higher faculties of their minds—is the only point they can be said to possess in common. From the characters they respectively adopt, these systems have been arranged into two classes—the *alphabetical* and the *arbitrary*—in the first of which the Roman letters of the ordinary alphabet are employed; in the latter arbitrary characters represent letters, words, and combinations of sounds. Of the alphabetical systems, the best are—1. Alston's system; 2. The American; 3. The French alphabetical; 4. Alston modified. Of the arbitrary systems, the best are—1. Lucas's system; 2. Frere's system; 3. Moon's; 4. Le Système Braille; 5. Le Système Carton.

The merits of these two great classes have been long and keenly canvassed by their respective propounders; but it is now generally admitted that of the two classes the alphabetical is the best; and that of the alphabetical systems Alston's is the most convenient for general use. The reasons for so decided a verdict in favour of the last-named method are briefly summed up in the *Tangible Typography* of E. C. Johnson, who thus defines the conditions which must be satisfied by every system intended to facilitate the intellectual improvement of the blind. "The system of embossed printing for their use should embrace at least the following features:—1. It must resemble as nearly as possible the type in ordinary use among those who have eyesight; (*a*) that the blind scholar learning to read may have every possible help from words which he may have formerly seen, but which now his fingers must decipher; (*b*) that he may derive help in learning from any one who can read an ordinary book; or, if needful, that his friend may be able to read to him. 2. It

Blind Coal ‖ Bloch.

must present the words correctly spelt in full, that when he learns to write, he may do so in a correct manner which others can read. 3. The raised characters must be clear, sharp, and well defined, which the finger hardened by long work, and the keen soft touch of the little child, may be alike able to discern." No system at present in use fulfils all these conditions save Alston's, and those framed upon its model.

Lucas's system is a stenographic one, differing however, from all stenographic systems in this, that the characters occupy more space than if the words were all written at full length in Roman capitals. The New Testament in Alston's system is comprised within 623 pages, whereas in Lucas's it occupies 841.

Mr Frere's system is also a stenographic one, based on the phonetic principle, or combination of elementary sounds. His alphabet consists of 29 arbitrary symbols, to each of which is attached a short descriptive versicle, intended to fix more strongly in the memory of the learner the force of the symbol. The vowels are represented by simple dots, which in different positions denote different vowels, and are divided into five long and five short. Twelve rules in doggrel metre are supplied, which teach the learner how to supply the omitted vowels correctly.

Moon's is perhaps more difficult and intricate than either Lucas's or Frere's. Its principles are thus propounded by Mr Moon himself. "In order to avoid the complicated form of the Roman letter, and the still less discernible angular type, I have invented an alphabet, each letter of which is formed of two lines only: most of the letters bearing a partial resemblance to those in ordinary use. Nine forms placed in different positions represent the whole alphabet and numerals; one form serving for A, V, K, L, and X, and another for E, L, M, and Y, while there are but four contracted forms, *ment, ing, tion*, and *ness*." It will be found, however, on examination, that the resemblance between the letters of Mr Moon's alphabet, and the Roman capitals of that in common use is by no means so great as the above announcement would reasonably warrant us in expecting. As Mr Moon's system is moreover the most cumbrous and expensive that has yet been devised, it is not probable in the meantime that its adoption will be so general, or its success so great, as its author would seem to have anticipated. The New Testament has been printed according to the plan propounded in each of the five systems already enumerated. If it be taken as a standard of comparison for the whole five, their relative position will be as follows:—

Block.

Systems.	No. of Volumes.	No. of Pages.	Square inches in Page.	Price.
				£ s. d.
American	2	430	117	0 16 0
Alston's	4	623	90	2 0 0
Lucas's.....	9	841	70	2 0 0
Frere's.....	8	733	110	2 10 0
Moon's	9	...	110	4 10 0

BLIND COAL, or ANTHRACITE, corresponds to the glance coal of England, and the stone coal of Wales. It is very common in Scotland and in Ireland, as well as in many parts of the Continent; and in America it is the staple fuel. See COAL. Its application to the useful arts is given in the article SMELTING. See also MINERALOGY.

BLINDING, a species of punishment anciently inflicted on thieves, adulterers, perjurers, and others, and from which the ancient Christians were not exempt. It was sometimes effected by a mixture of lime and vinegar, or scalding vinegar, poured into the eyes; sometimes a rope was twisted round the head till the eyes started out. In the middle ages, this punishment was effected by holding a red-hot iron basin before the eyes. See ABACINARE.

BLINDNESS, PERIODICAL, is that which comes and goes by turns, according to the season of the moon, the time of day, and the like. *Diurnal* blindness is called *hemeralopia*. *Nocturnal* blindness, called also *nyctalopia*, is that which ensues on the setting of the sun in persons who see perfectly in the day, but become quite blind as night approaches. (See *Phil. Trans.* No. 159, p. 560; and a singular case related by Dr Samuel Pye in the *Medical Observ. and Inquir.* vol. i. p. 111.)

BLOCH, MARK ELIEZER, an eminent ichthyologist and helminthologist, born at Anspach, of very poor Jewish parents, about the year 1730. Having entered the employment of a surgeon at Hamburg, he was enabled by his own exertions to supply the want of early education, and made great progress in the study of anatomy, as well as in the other departments of medical science. He established himself as a physician at Berlin, and found means to collect there a valuable museum of the subjects of all the three kingdoms of nature, as well as an extensive library.

He applied himself, however, more particularly to those parts of natural history which are the most connected with the practice of physic; and, on occasion of a prize question of the academy of Copenhagen, he entered into a very elaborate examination of the different species of worms which are found in the bodies of other animals. In his essay on this subject, to which the prize was adjudged, he maintains that the parasitical species are only found within the animal body; and since they often occur in the fœtus, and in cavities which are completely inclosed, he infers that they must be generated in some unknown way, and not taken in with the food in the form of eggs. For the general remedy in cases of worms in the intestinal canal, he recommends large draughts of cold water, followed by cathartics. He has added to his Essay a complete classification and description of all the species of intestinal worms, accompanied by figures.

M. Bloch also published a variety of papers on different subjects of natural history, and of comparative anatomy and physiology, in the collections of the various academies of Germany, Holland, and Russia, particularly in that of the Friendly Society of Naturalists at Berlin. But his great work was his *Ichthyology*, which occupied the labour of a considerable portion of his life. His attention was first directed to the subject by receiving a present of a species of salmon, which he could not find described in the Linnæan *System of Nature;* and he discovered a number of similar omissions in Artedi, and in all former ichthyologists. He accordingly undertook to collect into one work everything that was known respecting the natural history of fishes, and to give figures of all the species; and he passed several summers by the sea-side, and among fishermen and their nets, comparing the descriptions of authors with nature, and taking bold sketches of the most interesting subjects, not uncommonly on board of the fishing boats which furnished them. His publication was encouraged by a large subscription, and it passed rapidly through five editions in German and in French. He made little or no alteration in the systematical arrangement of Artedi and Linnæus, although he was disposed to introduce into the classification some modifications depending on the structure of the gills, especially on the presence or absence of a fifth gill, without a bony arch; a character which affords some useful subdivisions of several genera. To the number of genera before established, he found it necessary to add nineteen new ones; and he described 176 new species, many of them inhabitants of the remotest parts of the ocean; and by the brilliancy of their colours, or the singularity of their forms, as much objects of popular admiration as of scientific curiosity.

In 1797 he paid a visit to Paris, where he was secure of finding a variety of collections of such subjects of natural history as had been inaccessible to him on the shores of the Baltic; and he returned to Berlin by way of Holland. His health, which had hitherto been unimpaired, began now to decline. He went to Carlsbad for its recovery, but his constitution was exhausted, and he died there on the 6th of August 1799. (Coquebert in *Rapport de la Société Philomathique*, vol. iv. 8vo, Par. 1800.) (T. Y.)

BLOCK, an instrument or machine of wood, chiefly employed in the rigging and other parts of a ship, by means

Block-Machinery.

of which a facility is given to the hoisting or lowering of the masts, yards, and sails, or to the moving of any great weight, as guns, anchors, bales, casks, and the like. It is, in fact, a modification of the pulley, and the names may almost be considered as synonymous.

There is nothing in the appearance of a block which, to an unpractised eye, would seem to require any stretch of mental ingenuity or of manual dexterity to manufacture. It is a machine apparently so rude in its structure, and so simple in its contrivance, that the name was probably given to it from its general resemblance to a log of wood, as is obviously the case with a butcher's block, a barber's block, the block of the executioner, &c. Of the two constituent parts of a ship's block, the external *shell* and the internal *sheave*, every carpenter might make the one, and every turner the other; and yet, when blocks were made by the hand, it seldom happened that the several parts were adjusted to each other with sufficient accuracy, or that a strict uniformity was observed in the various sorts and sizes; without which they cannot be expected to work with that degree of ease and truth which is so desirable, and even necessary, in the important office they are designed to fulfil in the rigging and other parts of a ship.

BLOCK-MACHINERY. To acquire a greater degree of accuracy and uniformity, as well as celerity, in the making of blocks, Mr Walter Taylor of Southampton took out a patent in the year 1781, to secure to himself the benefit of some improvement he had made in the construction of the sheaves: he also shaped the shells, cut the timber, &c., by machinery, which was put in motion by water on the river Itchin, near Southampton, where he carried on so extensive a manufacture of blocks, as to be able to contract with the commissioners of the navy for nearly the whole supply of blocks and blockmakers' wares required for the use of the royal navy.

Mr Dunsterville of Plymouth had also a set of machines wrought by horse-power, for making the principal parts of blocks; his manufacture, however, of this article was not carried to any great extent; but the blocks made by this machinery, as well as those by Mr Taylor's, were said to be of a superior quality to those constructed by the hand, though still deficient in many respects.

No objection, however, would probably have been made to the quality of the blocks furnished by Mr Taylor, and used in the navy. It would rather appear that the enormous quantity consumed in the course of a long protracted war first called the attention of the admiralty or navy board to the possibility of some reduction being made in the expense of so indispensable and important an article in the naval service; and to the imprudence of depending entirely on a single contractor, whom accident or misfortune might disable from fulfilling his contract.

On these considerations, it seems to have been the intention of government to introduce, among other improvements then carrying on in Portsmouth dock-yard, a set of machines for making blocks, at the new wood-mills erected in that yard in 1801. About this time the improvements which had been introduced into private concerns were gradually finding their way into the great public establishments of the country. Still, however, an old maxim seemed to prevail, that government ought not to be its own manufacturer. This maxim, though perhaps generally just in political economy, is, we conceive, neither just nor wise when applied to those articles which are of the first necessity in the royal navy. Indeed, where the safety of so many thousand lives depends wholly, as is sometimes the case, on the strength of materials and goodness of workmanship, it is most desirable that the whole ship, and every part of it, from the pin of a sheave to the sheet anchor, should be manufactured under the immediate superintendence of respectable officers in the royal service.

Block Machinery.

About this time, too, Mr Brunel (afterwards Sir Marc Isambart Brunel) had completed a working model of certain machines for constructing, by an improved method, the shells and sheaves of blocks. This model was submitted to the inspection of the lords commissioners of the admiralty, and by them referred to General Bentham, the inspector-general of naval works, who represented that, as the making of blocks was one of the purposes for which a part of the force of the steam-engine erecting at the wood-mills was intended to be applied, he did not hesitate to recommend the new machine, as an invention which would enable the government to construct its own blocks with a greater degree of celerity and exactness than those which were then in use; and that it appeared to be well suited for manufacturing blocks of every description and size, with a degree of accuracy, uniformity, and cheapness, far beyond any of the methods hitherto practised. The adoption of Mr Brunel's machinery was the consequence of this opinion.

The advantages to be expected from blocks so made were stated by Mr Brunel to consist,—first, in bringing the shape of the outside of the shell to certain determined dimensions, so that those of the same size should actually be so, and not differ from one another, either in the proportion of the mortises, or in the shape and dimensions of the outside; secondly, in adding strength where it was wanted, by making the head and bottom more substantial, and less liable to split; and, thirdly, in leaving the wood between the two mortises thicker, so as to admit a sufficient bearing for the pins,—all of which would be accomplished without requiring any dexterity on the part of the workmen, but entirely by the operation of the machinery. The uniformity and exactness with which they were to be made would be attended with another important advantage to the public; the difficulty of counterfeiting them would act as a precaution against embezzlement. Another very considerable advantage would be derived from the employment of much waste wood in the dock-yard, usually sold for little or nothing, for firewood and other purposes.

The sheaves or shivers would, by this new machinery, be made so mathematically true, and so exact to each other in their thickness and diameters, that every sheave of any particular size would equally fit any shell of the size for which it was intended; and the inconvenience to which ordinary blocks are liable from the friction of the ropes against one or alternately both of the sides of the mortises, was intended to be removed by placing a sheet of metal on the upper part of the mortise, bent to the proper shape by an engine adapted for the purpose. Brunel also proposed a new form for the *clue-line* and *clue-garnet* blocks, so as to secure the sails from splitting, by preventing the points of the sails getting into the blocks; which has since been adopted and greatly approved of in the navy.

In the sheaves, instead of the double coak or cogue inserted in two halves, he substituted a mixed metal coak of a new and particular form, which will be described hereafter, of increased strength and durability. This coak was to be cast with precision in moulds, and fitted by an engine with the greatest nicety; and the pins or axes of the sheaves were to be of wrought iron, case-hardened and coated with tin, which would preserve the iron from rust in the parts which are not kept free from it by friction; as it has been found by experience that, however tight the pin be forced into the shells, the water will insinuate itself and corrode the pin; and when this is the case, the rust soon extends itself to the parts on which the sheave turns, and renders it unfit for use.

From the machines that were already completed for manufacturing blocks of certain dimensions, Mr Brunel

Block-machinery. was enabled to make a calculation of the saving as to the first cost, compared with the contract prices, which would be effected by the adoption of his invention. It was as under:

	Blocks of 8 inches.	12 inches.	16 inches.	21 inches.
	s. d.	s. d.	s. d.	s. d.
Brunell's prices.....	1 8¾	4 5	8 11½	18 1¾
Contract prices.....	2 3½	6 11½	13 6	27 0¾
Saving in first cost...	0 6¼	2 6½	4 6½	8 10¾

These savings, if realized to the full extent, were probably not more important than the increased strength, durability, and facility of working, which have been gained by the adoption of the block-machinery.

Those parts of the machinery which Brunel had completed in London under his patent were transferred to Portsmouth, and, in the course of the year 1804, were in operation; but the increased number of machines, the improvements that suggested themselves to the ingenious inventor, the application of other machines for making dead-eyes, trucks, and all manner of block-maker's wares, besides circular and upright saws, lathes, engines for turning pins, rivetting, polishing, &c. exercised his skill and ingenuity till the year 1808, when he considered the whole system to be complete in every part, and incapable, as far as he could judge, of further improvement. From that time to the present, the block-machinery has been in full and constant employment, without requiring the least alteration, and very little repair, beyond the unavoidable wear and tear of engines that are kept in almost constant motion; and, which is still more extraordinary, without requiring the aid of the inventor, though attended only by a few common workmen or labourers; but they are superintended by Mr Burr, the master of the wood-mills, who is considered as an able and ingenious machinist. The quantity of blocks of every description, manufactured by the machinery in Portsmouth wood-mills, is more than sufficient for the consumption of the whole navy and the board of ordnance, and if pushed to the utmost extent of the works, would also have been sufficient to supply the greater part of the shipping employed in the transport service.

It may be a matter of some curiosity to know the results of this system of machinery. It is put in motion by a steam-engine of thirty-two horses' power, which, however, is applied to a great variety of other purposes at the same time, wholly independent of the block-machinery. It has been found by calculation, that four men with the machinery, as it now stands, can complete the shells of as many blocks as fifty men could do by the old method; and that six men will furnish as many sheaves as before required sixty; and that these ten men, in displacing the labour of one hundred and ten men, can with ease finish in one year from 130,000 to 140,000 blocks of different sorts and sizes, the total value of which cannot be less than L.50,000; and this is stated to be the average number which has annually been made from the year 1808 to the conclusion of the war. This number is found to be fully sufficient for supplying the wear and tear of blocks, not only in the naval, but also in the ordnance department. The consumption, however, must depend on other circumstances besides the number of ships in commission, and will be greater or less according as ships have been employed on severe or easy service, in a good or bad climate, in fine or rough weather, &c. Nor will the number here stated appear to be enormous, when it is considered what a multitude of blocks are required for a thousand sail of ships, which at one period of the war were in commission at the same time. A ship of 74 guns, for instance, requires the following blocks for her equipment:

	No.
Single blocks from 5 to 26 inches.....	622
Double ditto from 7 to 26 ditto.....	130
Various other blocks, generally large, and several of them treble.....	74
For each of the 74 guns, 6 blocks.....	444
Total.....	1270
Besides dead-eyes, hearts, parrels, and puttock-plates, all manufactured at the mills.....	160
Of all kinds in a 74 gun ship,	1430

Block-machinery

The average number of ships of the line in commission appears to have been about 100; these would require 143,000 blocks; and allowing the remaining 900 ships and vessels to require only twice this number, there would be wanted for the first equipment of the 1000 ships of war 429,000 blocks, which, at the ordinary rate of making them at the mills, would require three years in completing.

The different sorts and sizes of blocks used in the navy exceed two hundred, and they vary from four to twenty-eight inches in length. Those above eighteen inches are more sparingly used, and the shells of the largest kinds are made in parts, and fitted together by hand.

To the completion of this ingenious machinery, Brunel gave his whole attention from the month of September 1802 to June 1808, during which time he received no other compensation beyond the daily allowance of one guinea; but as it was now in full operation, and ascertained to be capable of making a sufficient number of blocks for the whole naval and ordnance departments, it became a question in what manner the author of the invention should be rewarded. It was suggested by General Bentham, and agreed to by Brunel, that the savings of one year, as compared with the contract prices, would be a fair and not an unreasonable remuneration for the time, labour, and ingenuity bestowed on these extraordinary machines. It was no easy matter, however, to ascertain with precision what the actual savings amounted to.

Mr Brunel, by estimate, made them amount to.....	L.21,174	0	0
Mr Rogers, clerk to General Bentham, by estimate.....	12,742	0	0
General Bentham, after going into every possible detail of expense with the utmost minuteness that could be expected in a private manufacturing concern, calculated them at.....	L.16,621	0	0
Add six years' allowance at a guinea a-day, about.....	2,400	0	0
For the working-model.....	1,000	0	0
Total amount received by Brunel, about	L.20,000	0	0

Supposing, therefore, the whole cost of the buildings, steam-engine, machinery, interest of money, &c. to amount (which we understand to be about the mark) to L.53,000, and the net compensation for profits to about L.18,000, the whole expense of the concern was completely cleared in four years. The savings of L.18,000 on one year's manufactured articles of the value of L.50,000 amounts to something more than Brunel had originally made it by computation.

It would occupy too much space to enter into a minute description, and require more time than we can spare to prepare engravings in detail, of the various complicated systems of machinery that are employed for the completion of a block; and, after all, they would afford but little use or instruction, excepting perhaps to a professed machinist; and perspective views of the several systems would tend rather to mislead or confuse than to inform the

Block-machinery.

general reader. But as everybody who happens to inspect Portsmouth dock-yard makes a point of visiting the block-machinery, we think it may be of some use, in conveying a general idea of the most striking parts of the machinery, by following the process of making a block from the rough unsided tree, till the last finish is given to it.

We have stated that the original intention of the building was that of a wood-mill, in which all manner of sawing, turning, boring, rabbetting, and the like, was to be performed, and that the block-machinery was superadded to the first design, with which, however, it has interfered so little, that, in addition to the immense number of blocks manufactured at the mill, upwards of a hundred different articles of wood-work are made by other machinery, put in motion by the same steam-engine, from the boring of a pump of forty feet in length, to the turning of a button for the knob or handle of a drawer. (See DOCK-YARD, PORTSMOUTH.) Lest, however, the engine, with such a variety of work, might be overloaded, a second engine has been added, to assist, if found necessary, or to be substituted in the event of accident happening to the other. Among the many ingenious machines belonging to the wood-mills, exclusive of those for making blocks, one of very great effect, and at the same time great simplicity, is a circular saw for cutting rabbets in the edges of deal planks, invented by Mr Burr, the superintending master of the wood-mills.

The whole of the machinery in these mills is put in motion by straps passing over drum-heads, by which the several movements, numerous as they are, are carried on without the least noise; and all the engine-work, and every part of the machinery, are so truly made, and so firmly put together, and work with such accuracy in all their motions, that though the spectator is surrounded on all sides with movements in every possible direction, and some most rapid and violent, the only noise that disturbs him arises from the cutting, boring, turning, polishing, and other instruments which are actually in contact with the work that is under execution, and none of it from the working of the machinery. All the iron work, of which it is chiefly composed, was made by Mawdsley; and there is but another workman, perhaps, in the united kingdom, who could have finished the engines in a manner so worthy of the invention.

The first wing of the building is chiefly occupied by upright and circular saws, used for a variety of purposes not immediately connected with the making of blocks. The only operation for this department is that of converting the rough timber, which is generally elm or ash, most commonly the former, into its proper scantling; that is to say, squaring it by the upright or straight-cutting saw, and then, by a circular saw, cross-cutting it into a certain number of parallelopipedons, whose lengths may bear the required proportion to the thickness of the log. Some of these pieces are again cut longitudinally, according to the thickness that may be required for the shell of the block, especially those for single and double blocks, which of course are thinner than three and four-fold blocks. This operation is performed by what is called a ripping-saw. The logs thus cut out are then taken into the second wing of the wood-mills, where the machinery peculiar for the construction of blocks is erected; and here the first process may be said to commence in making the SHELL.

This operation is performed by the *Boring Machine*, which, by means of a centre bit applied to the middle of the shell, bores a hole for the centre pin of the sheave, while another bores one, two, or three holes, at right angles to the direction of the first, to admit the first stroke of the chisel, and, at the same time, to serve for the head of the mortise or mortises, according as the intended block is to contain one, two, or three sheaves. When thus bored, the log is carried from hence to the

Block-machinery.

Mortising Machine, which is an ingenious and striking piece of mechanism. The block being firmly fixed on a movable carriage, the latter is so contrived as to be made to advance to the cutting chisels, which are set fast in a movable frame. Every time the frame with the chisels ascends, the block in its carriage advances a little, so as to present to the chisels a fresh surface of wood to be acted upon at each stroke of their descent; and this up and down motion is continued with such rapidity, that the chisels make from one hundred to one hundred and thirty strokes in a minute, until the prescribed length has been mortised out; when, by raising a handle, which is done by a boy, the machine is stopped precisely when the chisels stand at their greatest elevation; and are thus left in the proper position, ready to commence a second operation. No harm, however, would happen, either to the block or the machinery, should the attending boy neglect to stop the work at the proper time, or even to fall asleep, notwithstanding the force and rapidity of the stroke; for, by a particular contrivance, the farther advance of the block is stopped, and the chisels, therefore, act in full space, and cut only the air. It is, indeed, a general characteristic of Brunel's machinery, to be so constructed as to carry with it a defence or protection against its own operations, and to counteract all ill effects that might otherwise arise from any neglect or inattention of the workmen.

The chips cut by the chisels are thrust out of the mortise by small pieces of steel attached to and projecting from the back of each chisel. They are each of them, besides, armed with two cutters placed at right angles to the edge, called *scribers*, which mark out the width of the chip to be cut by the chisel at each stroke. These scribers answer another purpose; their cutting is so true as to leave the two sides of the mortise so perfectly smooth as to require no further trimming or polishing.

The next process is to remove the block from the mortising machine to a circular saw, in order to have the four corners taken off, by which operation it is reduced to an octagonal shape. This saw being fixed into a table or bench, the workman has nothing more to do than to slide each log along the surface of the table, in the direction of the line marked out for the saw to cut it.

The next operation is to place the block upon the *Shaping Machine*. This is perhaps one of the most ingenious and most effective contrivances in the whole machinery of the wood-mills. It consists principally of two equal and parallel circular wheels moving on the same axis, to which one of them is firmly fixed, but on which the other is made to slide; so that these two wheels may be placed at any given distance from each other, and blocks of any size admitted between their two rims or peripheries. For this purpose, both rims are divided into ten equal parts, for the reception of ten blocks, which are firmly and immovably fixed between the two wheels. When the double wheel with its ten attached blocks is put in motion, the outer surfaces of the blocks, or those which are farthest from the centre, strike with great violence against the edge of a chisel or gouge fixed in a movable frame, which, being made to slide in a curved direction in the line of the axis, cuts those outward faces of the blocks to their proper curvature, which can be altered in any way the workman pleases, by a contrivance attached to the cutting tool. As soon as the tool has traversed the whole length of the block, or over the space contained between the two peripheries of the wheels, the machine is thrown out of the gear, and its prodigious velocity checked by a particular contrivance. The ten

Block-machinery.

blocks are then, by a single operation, and without removing them, each turned one fourth part round, and another fourth part of their surface brought outwards, which, being exposed to the cutting instrument traversing in the same direction as before, have the same curvature given to these new surfaces. A third side is then turned outwards, and, after that, the fourth and last side, when the whole ten blocks are completely shaped, and ten other octagonal logs applied to the peripheries to undergo the same operation.

The immense velocity with which the wheels revolve, and the great weight with which their peripheries are loaded, would make it dangerous to the workmen or bye-standers, if, by the violence of the centrifugal force, any of the blocks should happen to be thrown off from the rim of the wheels; to prevent the possibility of such an accident, an iron cage or guard is placed between the workman and the machine.

The shell of the block being now mortised and completely shapen, the last operation is performed by the *Scoring Machine*, which, by means of cutters, scoops out a groove round the longer diameter of the block, deepest at the ends, and vanishing to the central hole for the pin on which the sheave turns. The intention of this groove or channel is to receive the hempen or iron strap which surrounds the block. The only thing that now remains for completing the shell, is the removal of the little roughnesses from the surface, and giving to it a kind of polish, which is done by the hand.

The Sheaves. The wood generally used for making sheaves is lignumvitæ, but iron or bell-metal have occasionally been substituted for this wood. An attempt was made to introduce sheaves of a kind of porcelain, which answered well enough for some particular purposes, but were not to be trusted in situations where they were liable to sudden jerks and irregular motions. In the navy they are almost invariably of lignumvitæ, a few perhaps of ebony. The machinery employed for making this part of the block consists of a *Circular Saw*, by which the log is cut into plates of the thickness required for the sheaves, according to their several diameters. These plates are next carried to a *Crown Saw*, which bores the central hole, and at the same time reduces them to a perfect circle of the assigned diameter. The sheave, thus shaped, is next brought to the *Coaking Machine*, a piece of mechanism not inferior in ingenuity to the *Shaping Machine* for the shells. It would be useless to attempt to describe by words the movements of this engine, but the effect of the operation is singularly curious. A small cutter, in traversing round the central hole of the sheave, forms a groove for the insertion of the coak or bush, the shape of which is that of three semicircles, not concentric with each other, nor with the sheave, but each having a centre equally distant from that of the sheave. The manner in which the cutter traverses from the first to the second, and from this to the third semicircle, after finishing each of them, is exceedingly curious, and never fails to attract the particular notice of visitors. So very exact and accurate is this groove cut for the reception of the metal coak, and so uniform in their shape and size are the latter cast in moulds, that they are invariably found to fit each other so nicely and without preparation, that the tap of a hammer is sufficient to fix the coak in its place. The coaks are cast with small grooves or channels in the inside of their tubes, which serve to retain the oil or grease, without which it would soon ooze out, and the pin become dry.

The sheave, with its coak thus fitted in, is now taken to the *Drilling Machine*, which is kept in constant motion. In casting the coaks a mark is left in the centre of each of the three semicircles. This mark is applied by a boy to the point of the moving drill, which speedily goes through the two coaks and the intermediate wood of the sheave. A copper pin, cut from wire, of the proper length and thickness, is inserted into the holes thus drilled. And the sheave is then taken to the *Rivetting Hammer*, which is something like a small tilt hammer, and can easily be made to strike on the pin with greater or less velocity, according as the workman presses with more or less force on the treadle. The rivetting being performed, the next operation is that of broaching the central hole on which the sheave turns, by means of a steel drill or cutter.

Blockade.

The last process is that of turning a groove for the rope to run in round the periphery of the sheave, and this operation is performed by a lathe, which is so constructed, that while this groove is cutting round the rim of the sheave, another part of the engine is turning smooth the two surfaces or faces of the sheave; and this lathe can be made to adapt itself to sheaves of different diameters.

The shell and the sheave being now completed, there remains only the iron pin, which, passing through the two sides of the former, serves as the axis on which the latter turns within the mortise. These pins are also made, turned, and polished by engines for the purpose, so that, with the exception of strapping by rope or iron, the whole block is completed at the wood-mills. It may here be remarked, that the French, in the dock-yard of Brest, have long been in the practice of making blocks by machinery; but they have not attempted anything like a shaping machine, nor any substitute for it, the external shape of the shell being made entirely by hand; nor have they such a coaking machine as that invented by Brunel. The machinery at Brest is put in motion by horses. (See Dock-Yard.) (J. B—W.)

BLOCKADE, in war, the shutting up of any place or port by a naval or military force, so as to cut off all communication with those who are without the hostile line.

There is, perhaps, no part of the law of nations which, in practice, presents so many perplexing questions as that which concerns the respective rights of neutral and belligerent states. No definite line of distinction has yet been drawn between the privileges of war and peace; and the consequence has been, that, in all the wars which have been waged in Europe, the general tranquillity of the world has been endangered by the jarring of these two different interests. It has commonly happened, too, that all these important questions have been agitated during a season of war; when the passions of the contending parties were keenly engaged in the dispute; when principles were already subverted; and when the minds of men, exasperated by the glaring infraction of acknowledged rights, were not in a state to agree on any system of general equity by which to regulate and reform the erring policy of states. In these circumstances, many points of international law, which appear to rest on the most obvious principles, and which are very clearly settled in the writings of civilians, have, nevertheless, been the occasion in practice of no small controversy, and have frequently involved nations in all the miseries of protracted war. This has been in some measure manifested in the case of the *Rights of Blockade*, respecting which, though no difference of opinion has ever prevailed amongst speculative writers, a controversy arose during the late contests in Europe, which, along with other points, ultimately involved Great Britain in a war with the neutral powers. We propose, in the course of the subsequent observations, to state, 1*st*, The general principles from which the most approved writers have deduced the rights of blockade; and, 2*d*, To give a short account of the differences which took place between the neutral and the belligerent states, respecting the extent of those rights.

Blockade. In regulating the respective privileges of the neutral and the belligerent, it has generally been held as a fundamental principle, by writers on the law of nations, that those rights, from the exercise of which less benefit would accrue to the one party than detriment to the other, should be abandoned; and in all cases where the rights of peace and the rights of war happen to come into collision, the application of this rule will decide which of the two parties must yield to the convenience of the other. Thus the neutral state is debarred from carrying on any trade with either of the belligerents in warlike stores. The general right to a free trade is modified, in this particular instance, by the paramount rights of the belligerent. To refrain for a time from trading with an individual state in warlike stores, can at most only impose a trifling inconvenience on the neutral power, whilst the continuance of such a trade might terminate in the destruction of the belligerent. The detriment occasioned to the one party, by the existence of such a trade, is, in this manner, infinitely greater than the loss suffered by the other from its abandonment. Warlike stores, and whatever else bears a direct reference to war, are accordingly proscribed as unlawful articles of trade, and made liable to seizure by either of the belligerents. To this inconvenience the neutral is exposed, to avoid the greater inconvenience and damage which might fall on the belligerent by the licensing of such a trade. On the other hand, the neutral state enjoys the most unlimited freedom of trade in all other articles with either of the powers at war; and though, by means of this beneficial intercourse, they may be both furnished with the means of carrying on a protracted contest, this is a contingent and incidental consequence of the trade, which, in its character, is substantially pacific, and which is attended with such great and immediate advantages, that they could not, with any regard to equity, be sacrificed to the remote convenience of the belligerent.

Applying these principles to a siege or to a blockade, it is evident that the belligerent who had an expensive scheme of hostile operations of either kind in dependence would be far more seriously injured by its interruption than the neutral would be benefited by a free intercourse with the blockaded place. On this ground, therefore, a belligerent who has formed a siege or a blockade, has an indisputable right to debar the neutral from all intercourse with those who are included within his lines; and any attempt to penetrate the blockade for the purposes of trade, subjects those who attempt it to destruction, and their properties to confiscation. The very existence, indeed, of a siege or a blockade, as a lawful act of hostility, implies the right of enforcing it by an indiscriminate exclusion of all who seek access to the besieged.

But although this view of the nature of a blockade, and of the rights attaching to it, is clearly laid down by all writers on the law of nations, and although it has been acknowledged in practice by all civilized states, a question was agitated in the late wars of Europe, between the neutral and the belligerent powers, as to the *degree* of restraint necessary to constitute a blockade, and, of course, to entitle the blockading party to all the rights consequent upon this scheme of operations; and it is this dispute which was, in a great measure, the occasion of a general war with the neutral powers.

The unexampled success which attended the naval operations of Great Britain, during the war with France, naturally suggested to her rulers the possibility of extending this species of annoyance, and of converting the all-powerful navy which they possessed into an instrument of active hostility. With this view, instead of confining its efforts to the mere watching of the enemy's already ruined trade, it was resolved to give greater scope to such an immense engine of maritime power, by placing under Blockade. blockade the enemy's ports, the mouths of navigable rivers, and even extensive tracts of his coast. Proclamations to this effect were accordingly issued; and the neutral trader was duly warned off, and prohibited, under the peril of detention, from all intercourse with the interdicted coast. But the legality of these blockades by proclamation being disputed, both by the neutral powers and by the enemy, their execution was resisted by a counter-decree, which, on the plea of retaliation, placed under blockade the whole island of Great Britain, and subjected all neutral vessels to detention and capture which should have been found touching at any of its ports. On the same plea of retaliation, several decrees, or orders in council, were issued by Britain, ordaining, that no neutral vessel should have any intercourse with France and her dependencies, except such vessel should first touch at a British port, where, in some cases, the cargo was to be landed, and was to pay certain duties to the British government. From this period the maxims of equity, and the rules of international law, were set aside, and the ocean became a scene of proscription and pillage. All this anarchy having originated in a disagreement respecting the nature and extent of a blockade, it becomes of importance to bring back the question to its true elements, and to fix the principles by which alone it should be settled.

The object of a blockade is to reduce the inhabitants of the blockaded town to such straits that they shall be forced to surrender to the discretion of their enemies in order to preserve their lives; and hence the legality of every blockade, except with a view to capture, has been questioned. But without entering into this question, it seems obvious that, in order to constitute the blockade of a town, either with a view to capture or to temporary annoyance, the line by which it is surrounded should be so complete as entirely to obstruct all access into the place. When a place is blockaded with a view to capture, the task of maintaining a real blockade may safely be left to the blockading party. But when a port is blockaded with a view to mere maritime annoyance, the case is widely different; because, in these circumstances, the belligerent will equally attain his end by maintaining the mere show of a blockade, while he is in possession of all its substantial rights. He may, to save himself expense and trouble, relax the blockade of his enemy's ports, while he enforces the exclusion of all neutrals as rigorously as if he were maintaining an effectual blockade; and, in this case, his proclamations, while they are issued ostensibly for the blockade of the enemy's ports, would, in reality, amount to edicts for the suppression of the neutral trade. The urgent, immediate, and obvious interests of the neutral would here be sacrificed to the remote, and in many cases imaginary, convenience of the belligerent. An edict might be issued for the blockade of the enemy's ports, or of extensive tracts of his coast, round which no hostile line could ever be drawn so as to constitute a real blockade; and the whole trade of the neutral, with those interdicted parts of the enemy's territory, would be immediately annihilated at the arbitrary mandate of one of the belligerents. Instead of being carried on as a matter of right, instead of being regarded as a common benefit to the civilized world, and on this account as proper to be cherished and encouraged, the neutral trade would, under such a system, be looked upon in the light of a tolerated evil, existing only by the sufferance of those who imagined they had an interest in obstructing and in crushing it. The law of nations is not a partial system, modelled to suit the convenience of one party. It is a system of general equity, and its edicts are founded on a comprehensive view of what is for the com-

Blockzyl || Blois.

mon welfare and protection. In this view, then, the consequences to the neutral of those extensive and nominal blockades are sufficient to constitute them illegal. The damage to the neutral is infinitely greater than the benefit to the belligerent. The rights of blockade, and the limitation of those rights, must stand upon the same principle of justice and of public law; and their extension beyond this equitable principle must terminate in universal confusion and anarchy.

In opposition to these arguments in favour of the neutral powers, it has been urged that the new system of naval annoyance, introduced by Great Britain in 1806, was legal according to the strictest construction of the law of blockade, because the proclamations for interrupting all intercourse between the different parts of the French coast were not issued until it was ascertained, by the most particular inquiries, that Great Britain possessed an effectual naval force to blockade the enemy's coast from Brest harbour to the mouth of the Elbe. It is solely upon this principle that the ministers of our country maintained the legality of those blockades; and any breach in the line of blockade, they admitted, would be sufficient to constitute them illegal. Such, then, is the state of this important controversy, which seems to resolve itself into a mere question of fact, namely, whether the blockading power has actually carried into effect the blockade, of which notice by proclamation has been given to the neutral powers.

At the conclusion of the last treaty between Great Britain and America, no settlement of these disputed questions took place. The main war between the European belligerents, out of which the American dispute had incidentally sprung, being at an end, the controversy respecting rights which could only be exercised in a state of war had lost all practical importance. It had become a mere question of abstract right, the decision of which was wisely adjourned by the powers at war, and not suffered to clog the work of a general peace. It is likely, however, that on the breaking out of any new war, this and other questions of a like nature would recur, and on this account it might be of importance to the future peace of the world if these questions could be settled according to some acknowledged rule of equity or policy, and that without delay. (D. B—N.)

BLOCKZYL, a town of Overyssel, in the Netherlands, on the river Aa, at its junction with the Zuyder Zee. It has a port sufficient to contain 200 vessels. Its fortifications, which were considerable, have been allowed to fall to decay. Long. 5. 52. E. Lat. 52. 45. N. Pop. 1650.

BLOEMART, Abraham, a Dutch historical painter, born at Gorkum in 1567, who also painted landscapes with good effect, and etched with considerable skill. He died in 1647. His son Cornelius was an eminent engraver, and remarkable for the softness and purity of his burin.

BLOIS, the capital of an arrondissement of the same name, and also of the department of Loire et Cher in France, is pleasantly situated in the form of an amphitheatre on the steep slope of a hill on the right bank of the Loire, 35 miles S.W. of Orleans. The town itself cannot be said to be either handsome or well built; on the contrary, the houses are generally mean, and the streets narrow and crooked. It contains, however, several remarkable monuments of antiquity. The castle is an immense structure built at different periods, part of it as early as the thirteenth century. Here Louis XII. was born, and the Duke of Guise and his brother the cardinal basely murdered by the command of Henry III. It is now used as barracks. Among its other remarkable buildings are the Hotel de Ville, the episcopal palace, now the Hotel of the Prefecture, the Cathedral, the Church of St Vincent, &c. An ancient aqueduct, cut in the solid rock by the Romans, conveys the waters of several springs to a reservoir, whence they are distributed to different parts of the town. It is the seat of a bishopric founded by Louis XIV., and has a communal college, normal school, diocesan seminary, botanical garden, theatre, and public library. It manufactures gloves, hosiery, hardware, and leather, and has an extensive trade in wine, timber, brandy, &c. Population (1851) of town, 16,104; of arrondissement, 131,817.

Blond || Blood.

BLOND, J. Christopher le, a painter of portraits and other subjects in miniature, was born at Frankfort in 1670. He became known at Rome in the year 1716, being at that time painter to the Count Martinetz, ambassador at that court. He next went to Amsterdam; and, after some years' residence in the Low Countries, he came to England, where he established a new method of printing mezzotinto plates in colours, so as to imitate the pictures from which they were copied. This invention,—which was not his own, but borrowed from Lastman and others,—consisted in having several mezzotinto plates for one piece, each expressing different shades and parts of the piece in different colours. Le Blond next embarked in a scheme for copying the cartoons of Raphael in tapestry, and made drawings from them for that purpose. Houses were built and looms erected at the Mulberry Ground at Chelsea; but the contributions not being equal to the first expectations, the scheme was suddenly defeated, and Le Blond disappeared, to the no small dissatisfaction of those who were engaged with him. He died in an hospital at Paris in 1740. Le Blond explained his art in a book entitled *Il Colorito*, published in 1730, and he was also the author of a treatise in French on Ideal Beauty, which was published in 1732, and has since been translated into English.

BLONDEL, a troubadour, the friend and companion of the English Richard (Cœur de Lion) to the Holy Land. He is said to have discovered the place where his master was confined by his singing, when the gallant crusader was imprisoned by the mean revenge of the Duke of Austria, though modern scepticism has thrown doubts on the minstrel's part in that event. (Berrington's *Richard I.*)

Blondel, *David*, a Protestant minister, distinguished by his skill in ecclesiastical and civil history, was born at Chalons-sur-Marne, and was admitted to the ministry at a synod of the Isle of France in 1614. He soon made himself known by certain learned works, and in 1650 he succeeded G. J. Vossius in the professorship of history at Amsterdam. Bayle says he had a very singular way of studying. He lay on the ground, and had around him the books which he wanted for the work he was composing. He died in 1655.

Blondel, *François*, an eminent architect, born at Ribemont in Picardy, A.D. 1617. He was employed in various negotiations; arrived at the dignity of marechal-de-camp and counsellor of state; and instructed the dauphin of France in mathematics. He was also made member of the Academy of Sciences, and director of the Academy of Architecture. He died at Paris in 1688.

BLONDUS, Flavius, an antiquary and historian, born at Forli in 1388. He was secretary to Eugenius IV. and several of the popes. Besides other works he wrote a history extending from the year 400 to 1440. He died in 1463.

BLOOD. See Anatomy and Physiology, Animal.

Religious uses of Blood. Amongst the ancients blood was used for the sealing and ratifying of covenants and alliances, on which occasions the contracting parties drank a little of each other's blood; and also for appeasing the manes of the dead, in order to which blood was offered on their tombs as part of the funeral ceremony.

The blood of victims was anciently the portion of the gods; and accordingly it was poured or sprinkled on the altars in oblation to them. But the priests made another use of blood, namely, for divination; the streaming of blood being held a prodigy or omen of evil.

The Roman priests were not unacquainted with the use of blood in miracles; and they had their fluxes of blood from images, ready to serve a turn, as, for instance, that said to have streamed from the statue of Minerva at Modena before the battle at that place. But we know not whether, in this

Blood. species of legerdemain, their successors have not gone beyond them. How many are the relations, in ecclesiastical writers, of madonnas, crucifixes, and wafers, bleeding? The liquefaction of the blood of St Januarius at Naples, repeated annually for so many ages, seems to transcend all the frauds of the Grecian or Roman priesthood. But the chemists at last got into the secret; and M. Neumann of Berlin performed the miracle of the liquefaction of dried blood, with all the circumstances of the Neapolitan experiment.

Amongst the schoolmen we find a famous dispute, under Pope Pius II., whether the blood of Christ, which fell from him in the three days' passion, retained or lost the hypostatic union; and consequently whether it was the proper object of adoration. The Dominicans maintained the former, the Franciscans the latter. But the Dominican doctrine gained the ascendency, as being fitted to favour the profits of the monks, who becoming somehow possessed, as they said, of a few drops of this precious liquor, were certain of receiving ample offerings from the deluded laity, who flocked to pay their homage to the sacred relic. Joseph of Arimathea is said to have first brought into Britain two silver vessels filled with the blood of Christ, which by his order was buried in his tomb. King Henry III. had a crystal, containing a portion of the same blood, sent him by the master of the temple of Jerusalem, attested with the seals of the patriarch; which treasure the king committed to the church of St Peter's, Westminster, and obtained from the bishops an indulgence of six years and a hundred and sixteen days to all who should visit it. And Matthew Paris assures us, that the object of the king in summoning his nobles and prelates to celebrate the feast of St Edward in St Peter's Church was chiefly *pro veneratione sancti sanguinis Christi nuper adepti*, in veneration of the holy blood of Christ lately acquired. Divers others of our monasteries were possessed of this profitable relic; as the college of Bons-Hommes at Ashridge, and the abbey of Hales, to which it was given by Henry, son of Richard, duke of Cornwall and king of the Romans. This supposititious blood was resorted to by a great concourse of people for devotion and adoration; till, in 1583, when the Reformation commenced, it was perceived to be only honey clarified and coloured with saffron, as was shown at St Paul's cross by the bishop of Rochester. The like discovery was made of the blood of Christ found among the relics in the abbey of Feschamp in Normandy, pretended to have been preserved by Nicodemus when he took the body from the cross, and given to that abbey by William duke of Normandy. It was buried by his son Richard, and again discovered in 1171, and attended with different miracles; but the cheat, which had long been winked at, was at length exposed, and a relation of it is given by Speed.

Avenger of Blood, among the Jews, was the next of kin to the person murdered, who was authorized to pursue the murderer, and, unless he found shelter in one of the cities of refuge or sanctuaries, to take life for life.

Ecclesiastical judges retire when judgment is to be given in cases of blood, by reason of the maxim, *Ecclesia non novit sanguinem*. The church condemns no person to death; and by law, its members become disabled from their functions by the effusion of blood.

Blood-Hound, the *canis sagax* of Linnæus, *le chien courant* of Buffon, the *sleuthounde* of the Scots, a hound or dog, with long, smooth, and pendulous ears. It was a dog of great use, and in high esteem with our ancestors, being employed to recover any game that had escaped wounded from the hunter, or been killed and stolen out of the forest. It was remarkable for the acuteness of smell, tracing the lost beast by the blood it had spilt, from which the name is derived. This species could, with the utmost certainty, discover the thief by following his footsteps, let his flight be rapid, and through the most secret and thickest coverts; nor would it cease its pursuit till it had taken the felon.

The true blood-hound was large, strong, muscular, broad-breasted, of a stern countenance, of a deep tan colour, and generally marked with a black spot above each eye.

Blood-Whyte ‖ Bloomfield

Blood-Whyte, or *Blood-wyte*, in ancient law, signified a customary amercement paid as a composition for the shedding of blood. The word is also written *blodwhite*, *blodwita*, *blodwyta*, *bloodwit*, *blodwit*, *bloudwit*, *bluidweit*; being formed from the Saxon *blud*, blood, and *vite* or *wite*, a fine or penalty. It also denotes an exemption from this penalty, granted by the king to certain persons and communities as a special favour. King Henry II. granted to all tenants within the honour of Wallingford, *Ut quieti sint de hidagio et blodwite et bredwite*.

Blood, *Thomas*, generally known by the appellation of *Colonel Blood*, was a disbanded officer of Oliver Cromwell's, famous for his daring crimes and his good fortune. He was first distinguished by engaging in a conspiracy to surprise the castle of Dublin; but this scheme was defeated by the vigilance of the duke of Ormond, and some of Blood's accomplices were executed. Escaping to England, he meditated revenge against Ormond, and actually seized him one night in his coach in St James's Street, where he might have finished his purpose if he had not studied refinements in his vengeance. He bound his captive on horseback behind one of his associates, resolving to hang him at Tyburn, with a paper pinned to his breast; but when they had got into the fields, the duke, in his efforts for liberty, threw himself and the assassin to whom he was fastened to the ground; and, while they were struggling in the mire, his grace was rescued by his servants. But the authors of this attempt were not then discovered. A little while after, in 1671, Blood formed the design of carrying off the crown and regalia from the Tower; an attempt which had very nearly been successful. He had bound and wounded Edwards, the keeper of the jewel-office, and had escaped out of the Tower with his prey; but he was overtaken and seized, together with some of his associates. One of these was known to have been concerned in the attempt upon Ormond, and Blood was immediately concluded to be the ringleader. When questioned, he frankly avowed the enterprise, but refused to discover his accomplices. All these extraordinary circumstances made him the general subject of conversation; and the king was moved with an idle curiosity to see and speak with a person so noted for his courage and his crimes. Whether the communications at this interview excited the fear or admiration of the king, they confirmed his resolution of granting a pardon to Blood. Charles carried his kindness to Blood still further, granting him an estate of L.500 a-year in Ireland, encouraging his attendance about his person, and showing him great countenance. Whilst old Edwards, who had bravely ventured his life in defending the crown and regalia, was forgotten and neglected, this villain became a kind of royal favourite. Blood enjoyed his pension about ten years; but at last being charged with fixing an imputation of a scandalous nature on the Duke of Buckingham, he was obliged to find bail to avoid being thrown into prison, and before the trial came on he died at his house in Westminster, August 24. 1680.

BLOODSTONE, or Heliotrope, in *Mineralogy*, a chalcedony or agate of a deep green colour, with blood-red spots interspersed through it. Tartary and Siberia are its chief localities. It occurs in Scotland in the isle of Rhum, in veins in trap rock.

BLOOMFIELD, Robert, the author of several pastoral poems of great beauty, was born of very humble parents at the village of Honington in Suffolk, in 1766. Without education but what a village school afforded, and losing his father at the age of eleven, he was apprenticed to a farmer, and could only improve his taste by perusing such books as he could borrow. Among these, Thomson seems to have been his favourite author, and *The Seasons* inspired him

Blow-pipe. by treating a mineral with that substance. Phosphate of ammonia is also sometimes used as a flux in the same manner as borax, and carbonate of soda; but both these, especially the latter, have the inconvenience of sinking into the charcoal, which borax is free from.

Characteristic phenomena of minerals treated by the blow-pipe.

Mention must be made here of a few of the most prominent phenomena, characteristic of different mineral substances when treated by the blow-pipe. Some minerals are fusible alone, such as garnet and felspar; the last, however, is rather difficult to fuse. Some are infusible, and change colour; bituminous shale loses its black colour, and becomes white; green and dark coloured steatite become white. Some dissolve in borax without effervescence, as agate, quartz, felspar, amiantus, garnet. Some dissolve in borax with effervescence. This is the case with carbonate of lime; it forms with borax a globule transparent whilst in fusion, but in cooling the globule becomes opaque, the lime being no longer held in solution by the borax, in like manner as the watery solutions of certain salts, saturated when hot, deposit a part of the salt on cooling. Some of the metals communicate peculiar colours to borax. Copper, in certain proportions, and at a certain degree of oxidation, gives a brown colour to borax when heated by the blow-pipe; cobalt gives a deep blue tinge; manganese communicates a violet colour; iron tinges borax brown, and, if in greater quantity, black. These colours are produced by the metals in a state of oxide. The smell emitted by some minerals when heated by the blow-pipe is another character serving to distinguish them. That of minerals containing sulphur is the peculiar suffocating smell of sulphureous gas; minerals that contain arsenic emit, when heated, a smell like that of garlic. The nature of some minerals is recognised by the particular form of crystallization which they assume in cooling. This is the case with phosphate of lead, which, after being fused, cools on the charcoal into an opaque white spheroidal polyhedron. Some ores are reduced to a metallic globule with great ease on the charcoal; thus the native sulphuret of lead, called galæna, being heated by the blow-pipe, the sulphur is driven off, and the lead remains in its metallic state. A small particle of silver may be melted by the blow-pipe; likewise gold, copper, and, Bergman says, cast-iron. Metallic zinc, when exposed to the flame of the blow-pipe on the charcoal, melts and burns with a bluish-green flame, and becomes covered with oxide, which flies off and floats in the air in light white flocks. Metallic antimony becomes red hot, and melts on the charcoal; and if the operator ceases to blow, a white fume rises, and oxide of antimony forms upon the globule, in whitish crystalline spiculæ; but if the globule, in a state of fusion, be thrown upon a brick floor, it runs along for a considerable way, rebounding several times, and leaving a trace of white oxide of antimony.

Some substances communicate colour to the flame of the blow-pipe. Muriate of copper, whose crystals are green, communicate a vivid green to the flame; sulphate and nitrate of copper, whose crystals are blue, likewise impart a green colour to the flame when they are exposed to its action. Some of the salts of strontian give a purple tinge to the flame.

Glass-blower's bellows.

The preceding observations relate to the blow-pipe worked by the breath. When it is required to continue the use of the blow-pipe so long that it would be fatiguing if the breath merely were employed, the glass-blower's table, fig. 9, is used. It consists of a double bellows, so fixed as to be worked by the foot, and to impel a current of air through a tin blow-pipe against the flame of a lamp fixed on the table. For the sake of durability, the blow-pipe is sometimes of brass, on which is screwed a nozzle of platina. The blow-pipe may have a stop-cock, as in fig. 9, serving to regulate the blast. The lamp has a cotton wick of nearly an inch in thickness; the wick is kept together by a tin wick-holder, which is soldered to the lamp; and melted tallow fills the lamp, and feeds the wick with fuel. In order to get rid of the smoke, which is in considerable quantity, there may be placed at a convenient distance above the flame a tin funnel ending in a tube, which conveys the smoke out of the room. A convenient method of carrying away the smoke from the glass-blowers' lamp is represented in fig. 13. It consists of a cover of thin sheet copper, which is placed on the table, covering the lamp and nozzle. The fore-part of this cover is open, so as to allow the jet of flame to pass freely. From the upper part of the cover two tubes run upwards for the exit of the smoke; and between these the glass-blower has a view of the object he is at work upon, whilst his eyes are screened from the light of the flame. The two tubes join above in one short tube; and over the open end of this short tube, at a small distance above, is a tube suspended from the ceiling by wires, which conveys the smoke into the chimney of the room. By a handle attached to the cover, the cover with its tubes is removed when it is necessary to trim the wick. The flame of gas from pit-coal may be used instead of a lamp, with a bellows of this kind.

Blow-pipe.

Water-pressure apparatus

The regularity of the blast in the double bellows is effected by means of a weight pressing on the air contained in the second compartment of the bellows; just in the same way as a stream of air is made to issue regularly from a tube fixed in the mouth of an inflated bladder, when a weight is placed on the bladder. A regular stream of air may also be obtained, by subjecting inclosed air to the pressure of a column of water, mercury, or some other liquid. If a vessel containing air, and open at the mouth, be plunged into the water with the mouth downwards, and if the water on the outside of the vessel rise higher than the surface of the water within the vessel, then the column of water, whose height is the difference of level, exercising its pressure, as all liquids do, in every direction, will act upwards on the inclosed air; the inclosed air, pressed and more condensed than the external air, will escape in a current, by a stop-cock opened on the top of the vessel for its issue; and this issue will continue till the surface of the exterior and interior water come to a level, when the air in the vessel will have the same density as the external air. The force with which the inclosed air is pressed is equal to the weight of a column of water whose height is the difference of levels, and whose base is the surface of water exposed to the inclosed air. The gasometers used by Lavoisier, to afford a stream of oxygen gas and a stream of hydrogen gas, for effecting the composition of water, are constructed upon this principle. An apparatus of the same nature has for many years been employed upon a great scale in different parts of Britain, to regulate the most powerful blast used in the arts,—that for reducing ironstone to the state of cast-iron. In blast-furnaces upon this construction, the blast is raised by means of a large cast-iron cylinder, which acts as a bellows, having a valve in the bottom that opens inwards, and that admits the air during the ascent of the piston; when the piston descends, the valve shuts, and the air is driven into a large parallelopipedal vessel, less in height than in the other dimensions, immersed in water, and having its under surface closed only by the water. In this vessel the air is pressed by the column of water, whose height is the distance between the surfaces of the exterior and interior water; and a pipe of issue, terminating in a nose-pipe, conducts the blast to the furnace.

Melograni's blow-pipe.

The blow-pipe of the Abbé Melograni of Naples, for the use of the mineralogist, operates by the pressure of water.

Blow-pipe. It is composed of two hollow globes, the upper filled with water, which, by running into the lower, forces the air contained in the lower to issue through a nozzle. This apparatus is described by Mr Greenough, in *Nicholson's Journal*, vol. ix. p. 25 and 143. It has some inconveniences, and does not appear ever to have come into much use.

Water-pressure blow-pipe for glass-blowers. The water-pressure apparatus, applied to the blow-pipe, of which a section is given at fig. 10, was contrived by Mr Tilley, an ingenious fancy glass-blower. It consists of a tin box with a partition in it, reaching within half an inch of the bottom; water is poured in, equal in bulk to three fourths of the capacity of the box. The water in the cavity DE is open, and subject to no other pressure but that of the atmosphere, being only covered by the lid of the vessel; the apartment F is closed at top, so as to be air-tight, and the water in it is pressed by the elasticity of the air confined in its upper part. The tube C has its lower extremity always plunged in water, so that when air is blown in through it, the return of the air by that tube is prevented. Before the apparatus is set to work, the surface of the water in both compartments is at the same height, both being pressed by air of the density of the surrounding air; but when air is blown in through C, the air rises through the water to the top of the compartment F; and as the only issue for the air is through the small aperture of the blow-pipe, by which it cannot escape nearly so fast as it is blown in, the air consequently becomes condensed in the upper part of the compartment F; and this condensed air pressing on the water in F more strongly than the atmosphere does on the water in DE, depresses the surface of the water in F, and causes it to rise in DE, which is effected by a portion of the water passing under the partition into the open compartment DE. Thus the pressure exerted by the column of water whose height is the difference of level of the water in DE, and of the water in F, forces the air from the compartment F through the blow-pipe *a*, which is directed against the flame of a lamp; and this pressure keeps up a constant blast till the water in the two compartments comes nearly to the same height. The degree of condensation of the inclosed air, and the height of the column of water pressing on the condensed air, are measures of each other, when much air is blown in, so as to occasion a considerable degree of condensation. The difference of level resulting is considerable; and the column of water, which is always re-acting with an equal and contrary pressure on the condensed air, causes it to issue with greater velocity from the blow-pipe. When the condensation diminishes, so does the column of water, and the velocity of the issuing stream of air. More air is to be blown in with the mouth through the tube C from time to time, so as to keep the blast regular. Mr Tilley is of opinion that this apparatus produces a more regular stream of air than a double bellows, and it has likewise the advantage that the operator is free from the trouble of moving a pedal. The dimensions of the vessel AA, which is either of tinned iron or of tinned copper, are seventeen inches in height, five inches in width, and nine in breadth; the lid of the vessel opens and shuts on hinges, and supports the tallow lamp B. The bent glass tube *a*, which terminates in a small hole, is fitted air-tight into a tin tube, which is made conical, and which forms the issue from the top of the compartment F; for this purpose paper is wrapped round the glass tube, and then cotton wick yarn, in a conical form, so that the glass tube thus clothed may fit tight into the socket, and may nevertheless be moved round, that the blast may act properly on the flame. The bent metal tube C is also fixed into its socket in the same manner: its junction with the socket is seen in fig. 10. There is a screen formed of a tin plate sliding vertically in grooves between two upright pieces of tin; the edge of this is seen at S, in fig. 10. It is intended to protect the eyes of the operator from the light of the lamp, whilst, at the same time, he can see the subject of his operation over the top of the screen. This screen is not soldered to the vessel, but is held fast by its foot being placed between the lid of the vessel and the top of the close chamber F. Two rests for supporting the operator's arms project, one from each side of the vessel; upon these the arms are placed when any substance is held to the flame. These rests are wrapped round with woollen list or leather, so as to be more convenient for leaning upon. The whole of the apparatus, including the lamp and case, weighs only three pounds and a half. When it is to be used, the vessel is fixed to a table or bench by means of a leather strap buckled to two loops, which are on the sides of the vessel opposite to each other; and the strap is passed under the table or bench. The long flat cotton wick is preferred by some glass-blowers to the usual round cotton wick. The lamp is filled with tallow, which melts after the lamp has been lighted for some time, and then it burns as freely as oil, and with a less offensive smell. When not in use the tallow becomes solid, and is more conveniently carried about than oil. Hogs' lard also does well for burning in this lamp. Some glass-blowers mix cocoa-nut oil, which is solid at the temperature of the climate of Britain, with hogs' lard, and find it to answer well in the lamp. The lamp is placed within another vessel, marked K, which supports it at a proper height, leaving a space between them, to receive any tallow that may run over the edge of the lamp. A wire bent at the end is convenient for trimming the wick, and forming it into a channel through which the stream of air is to be directed. It is convenient to have several lamps with wicks of different thicknesses, namely, one to hold two flat cottons of about one inch and a quarter broad, another to hold four, a third to hold six, or as much common wick-yarn as is equal to those wicks in bulk, and glass adjutages of different sized apertures to suit the different sized wicks. (See *Transactions of the Society for Encouraging Arts*, vol. xxxi.)

Blow-pipe.

Eolipile. The eolipile, fig. 11, has been applied to act as a blow-pipe. It is a hollow vessel of brass, sometimes made in form of a small kettle, sometimes in form of a ball of two inches in diameter, with a tube of brass that screws into it. The tube is to be screwed off in order to pour in alcohol by a small funnel, and then the tube being replaced, and heat applied to the bulb, the vapour of the alcohol issues from the small aperture of the tube, and being directed against the flame of a lamp, the flame is driven in a horizontal stream, such as the blow-pipe produces. The instrument has a safety valve, S, to prevent the danger of explosion, which might happen if the nozzle were stopped. The same wick that heats the bulb may serve to furnish the jet of flame, as is the case in the eolipile represented in fig. 11. This instrument has been proposed to be applied to the purposes of the mineralogist; but it does not appear to be either so readily put in action or so efficacious as the common blow-pipe, which is also simpler in its construction, less bulky, and more easily carried about.

Newman's blow-pipe. Mr Newman, philosophical instrument-maker, of Lisle Street, London, having observed that air condensed in a cavity required a considerable time to escape through a small aperture made to give it issue, contrived the apparatus represented at fig. 12, which acts as a blow-pipe. This apparatus consists of a strong plate-copper box, perfectly air-tight, three inches in width and height, and four in length; a condensing syringe to force air into the box; and an adjutage with a stop-cock at one end of the box,

Blow-pipe.

by which the issue of the air is regulated. The piston rod of the condensing syringe works through collars of leather in the cap, which has an aperture in the side, and a screw N connected with a stop-cock, which may be made to communicate with a jar, bladder, or gasometer, containing oxygen, hydrogen, or other gases. When this communication is made, and the condenser worked, the gas contained in the jar or bladder is thrown into the box, and issues through the adjutage upon the flame of a lamp placed near it. When the apparatus is worked with common air, a few strokes of the piston fills the chamber with compressed air. When the cock of the adjutage is opened, the air issues with great velocity in a small stream, and, when directed on the flame of a lamp, produces a jet of flame as the common blow-pipe does, but with more precision and regularity. The force of the stream of air is easily adjusted by opening more or less the stop-cock of the adjutage; and, when the box has been moderately charged, the stream will continue to issue uniformly for twenty minutes; when the strength of the blast begins to decline, it will be restored by working the syringe. The apparatus is very portable, and not liable to injury. It is made by Mr Newman, the inventor, with a lamp adapted to it, so as to pack up in a box not more than six inches in length and four inches in width and height, enough of space being left for other small articles; others he makes in boxes somewhat larger, so as to contain also a selection of chemical tests. (See *Journal of Science*, edited by the Royal Institution, No. 1.)

with a mixture of oxygen and hydrogen.

Sir Humphry Davy having discovered that the explosion from oxygen and hydrogen gases would not communicate through very small apertures, Mr Children proposed to him to employ Newman's blow-pipe for effecting a combustion of a mixture of oxygen and hydrogen gas issuing from a small aperture. This Sir Humphry did, and found that the flame produced an intense heat, which instantly fused bodies of a very refractory nature. Dr Clarke, professor of mineralogy at Cambridge, having consulted Sir Humphry on the subject, proceeded to expose a great variety of mineral substances to the flame, for the purpose of observing its effects upon each of them. The tube of glass through which the mixture of the two gases issues, is cemented on the pipe of issue of Newman's blow-pipe. The tube at first used by Dr Clarke was three inches in length, and the diameter of its cavity $\frac{1}{10}$th of an inch. The end of the tube was constantly breaking during the experiments, owing to the sudden changes of temperature, until at last he usually worked with a tube only one inch and three-eighths in length. When the current of gas is feeble, from the gas in the reservoir having come nearly to the same degree of density as the surrounding air, or from the current being suppressed in the beginning of an experiment, then the flame has a retrograde movement, passing up the capillary cavity of the tube about half an inch, and, after splitting the end of the glass tube, the flame goes out of itself; so that, even in this case, there is no danger of explosion. In order to try the effects of an explosion, four pints of a mixture of the two gases were condensed into the chest, which was all that the syringe could force into it. The glass tube was taken off, so that the diameter of the nose-pipe, by which the gas was to issue, was about one eighth of an inch. A burning spirit-lamp was placed at this aperture, and the stop-cock being opened by means of a long string attached to it, the whole gas exploded with a report like that of a cannon; the chest was burst, the stop-cock driven out, and one end of the chest was torn off and thrown against the wall of the room. This shows the danger of using the apparatus with too large an aperture, and the necessity of employing a capillary tube.

Blow-pipe || Blowing.

Dr Clarke's experiments.

When the mixture of the two gases is to be employed in Newman's blow-pipe, the chest is first exhausted of air, and then the gaseous mixture in a bladder, screwed on at N, is to be forced into the chest by the condensing syringe. The proportions of the two gases which Dr Clarke found to produce the greatest heat are, two volumes of hydrogen and one of oxygen gas. The intensity of the heat is much greater when the gases are pure; the oxygen procured from manganese does not produce nearly so great a heat as that got from the hyper-oxymuriate of potass. The intensity of the heat may be regulated by allowing the gas to issue in a more or less copious stream, which is done by turning the stop-cock. The heat, Dr Clarke thinks, is greater than that produced by the largest galvanic batteries. Most substances hitherto tried are fused by it, so that it is difficult to find supports for holding the subject of experiment to the flame. The supports employed by Dr Clarke were, charcoal, platina, a piece of tobacco-pipe, black lead. Lime, strontian, and alumine, were fused. The metal of strontian was got, and retained its lustre for some hours. The alkalies were fused and volatilized almost the instant they came in contact with the flame. Rock-crystal fused into a transparent glass full of bubbles. Quartz gave the same result. Opal fused into a pearly white enamel. Flint fused rapidly into a white frothy enamel. Blue sapphire melted into greenish glass balloons, ramified singularly. Foliated talc fused into a greenish glass. Peruvian emerald melted into a transparent and colourless glass, without bubbles. Lapis lazuli fused into transparent glass, with a slight tinge of green. Pure foliated native magnesia, from America, is the substance the most difficult of fusion; it is, however, at last reduced to a white opaque enamel. Agalmatolite of China fuses into a limpid colourless glass. Iceland spar is next in difficulty of fusion to the native magnesia; but it does at last melt into a limpid glass, and, during the process, gives an amethyst-coloured flame, as strontian does; the fusion of pure lime and of all its compounds is attended with a flame of the same colour. Diamond first became opaque, and then was gradually volatilized. Gold, fused along with borax, on a piece of tobacco pipe, was nearly all volatilized. Platina wire, $\frac{2}{10}$th of an inch in diameter, melted the instant it was brought into contact with the flame of the gas; the melted platina ran down in drops, and the wire burnt as iron wire does in oxygen gas. Brass wire burnt with a green flame, differing from the green flame that salts of copper give. Copper wire melted rapidly without burning. Iron wire burnt with brilliant scintillation. Plumbago melted into a bead which was attractable by the magnet. Blende or native sulphuret of zinc melted, and metallic zinc appeared in the centre of the melted mass. And metalloid oxide of manganese, crystallized in prisms, was reduced to a metallic state. (See Dr Clarke's Account of his Experiments, in the *Journal of Science*, edited at the Royal Institution, October 1816.) (W. A. C.)

BLOW-PIPE, a straight metal tube used by anatomists for inflating with the breath the collapsed vessels of the dead subject in order to ascertain their course. This tube is of an elongated conical form, six inches in length; the aperture of the large end being $\frac{4}{10}$ths of an inch in diameter, and that of the smaller end the size of a needle's point.

BLOWING, in a general sense, denotes an agitation of the air, whether performed with a pair of bellows, the mouth, a tube, or the like.

BLOWING, among gardeners, denotes the action of flowers in opening and displaying their leaves. In this sense, blowing is the same with flowering or blossoming.

The regular blowing season is the spring, although

Blowing Machines.

some plants have other extraordinary times and manners of blowing, as the Glastonbury thorn. Different flowers, also, as the tulip, close every evening, and blow again in the morning. Annual plants blow sooner or later according as their seeds are put in the ground; and hence the curious in gardening sow some every month in summer, to have a constant succession of flowers. The blowing of roses may be retarded by shearing off the buds as they are put forth.

Blowing of Glass, one of the methods of forming the various kinds of work in the glass manufacture. It is performed by dipping the point of an iron blow-pipe in the melted glass, and blowing through it with the mouth, according to the dimensions of the glass to be blown. See Glass.

Blowing of Tin denotes the melting its ore, after being first burnt to destroy the mundic.

BLOWING Machines, in the arts and manufactures, and in domestic economy, are instruments for producing a continued current of air, principally for the purpose of facilitating the combustion of fuel. The first idea of such a machine was doubtless derived from the lungs, which we are constantly in the habit of using for the purpose of blowing, but more especially in the simple and useful application of the blow-pipe.

Common bellows.

Of these different machines, the common bellows bears the greatest resemblance to the lungs, and was in all probability the first contrivance for artificial blowing. In the first instance, this instrument might be a simple bag, capable of distension by a mechanical force, the air being drawn in and pressed out of the same aperture in the manner of breathing. The first improvement upon this simple form would be to admit the air by a valve opening inwards when the bellows were distended, the blast outwards being from another aperture. This improvement consists in the air being admitted at a wider aperture, which fills the bellows in less time than would be required by the small pipe through which the air is allowed to escape. The blast, in this state of the machine, is not continuous, but in puffs, at intervals of time required for the air to enter the bellows through the valve; the blowing interval being to the filling interval as the areas of the apertures. This irregular blast was for some time remedied by employing two bellows which blew alternately, the blowing on one taking place while the other was filling. The inconvenience, however, was but partially remedied by this contrivance. The invention of what are called double bellows must have been considered a valuable acquisition in the art of blowing. But previous to describing these, it will be necessary to give a description of single bellows above mentioned.

Single bellows.

It will be needless, however, to say more than refer the reader to common domestic bellows, which are in every respect the same as the single bellows first used. The leather nailed to the upper and lower boards is prevented from collapsing, when the boards are separated, by a hoop of wood contained within, performing the office of the ribs in the sternum of animals, without which the breathing would not be performed. The lower board contains the valve which admits the air. When the two boards are separated, the air lifts the valve in entering the cavity. When full of air, the closing of the boards causes the air within to close the valve, thus preventing its return in that direction, and compels it to escape at the pipe, the mouth of which is called the nozle or nose-pipe.

Double bellows.

In order to conceive the construction of the double bellows, we have only to take a third board of exactly the same shape as the other two, and connect it with the lower board by a piece of leather similar to that of the single bellows, making two cavities exactly similar, and separated by the lower board of the single bellows, which now becomes the middle board of the double bellows. The third board we shall now call the lower board. This latter has a valve in it exactly similar to the first, which still retains its place in the new construction.

Blowing Machines.

The middle board is now fixed in a horizontal position, the pipe being placed to the fire to be blown. The lower board is held down by a weight, which keeps the lower cavity constantly full of air. The top board has a weight laid upon it, which presses all the air out of the upper cavity through the pipe.

The machinal action by which the blowing is performed is, first, to lift up the lower board. This forces the air from the lower into the upper cavity, the valve in the middle board preventing its return. The weight on the upper board now presses the air with a uniform blast through the pipe. During this time the lower board descends, which fills the lower cavity with air from the atmosphere; and this again rises and gives its contents to the upper cavity, and thence passes through the nose-pipe. Hence we see that that irregular puffing blast which belongs to the single bellows is here confined to the lower board, which supplies air to the upper cavity, while the upper board is constantly pressing uniformly upon the air in it. Although this is a considerable improvement upon the single bellows, it does not completely obviate the irregularity of the blast. So long as the lower board is not in action, the pressure on the upper board being uniform, the blast is the same. Every time, however, the bottom board rises to force the air into the upper cavity, an extra pressure is given to the air in the upper cavity, and a temporary puff is produced. In the application of bellows to the smith's forge, the continued blast was of less importance than in the blast-furnaces applied to the smelting or refining of ores. The single bellows are at present almost exclusively employed by anchor-smiths and cutlers; while the blacksmith and most others use double bellows, which are doubtless better for all purposes.

Wooden bellows.

In France and other parts of the Continent, bellows have been formed entirely of wood, instead of the flexible sides of leather, which serves to increase and diminish the capacity. The wooden bellows consist of two boxes, each open on one side, the one being just capable of containing the other; the outer box being placed with the mouth upwards, the other is made to descend into it with the mouth downwards, the latter being capable of moving up and down, while the other remains fixed. In the bottom of the fixed box is a valve like the common bellows, and a pipe on the same level to let out the blast. The change of capacity, by the motion of this box, causes the blast, and with less waste of power than that occasioned by the bending of the leather in the common bellows. This advantage is, however, probably more than compensated by the loss of air from the box not fitting on the sides. See a description of this and some other blowing-machines under Pneumatics.

Circular bellows.

The common smith's bellows have latterly been constructed of a circular form. The boards of these bellows are round, and the movable boards parallel to the horizon and to each other. We have given a view of this construction in Plate CVIII. figures 4 and 5. A is the blast-pipe, B the movable lower board, C the fixed board, into which the pipe is inserted, and D the upper movable board, on which is placed a weight to regulate the strength of the blast. Motion is given to the lower board by the lever L, and the chain H working on the roller R.

The form of these bellows being cylindrical, the weight required to produce a certain pressure and strength of blast will be easily determined. If the diameter be one foot, the area will be 113·19 inches. The most convenient and pro-

Blowing Machines.

per blast for smiths' bellows is about $\frac{5}{4}$ lb. upon the inch, or from that to $\frac{1}{2}$ lb. The upper board, in this case, would require a weight of 56·5 to give a blast equal to half a pound upon an inch. This pressure would give a velocity equal to about 207 feet in a second. If the diameter of the nose-pipe be changed, the number or length of the strokes, or both, must be changed, in order that the pressure and the corresponding density of the blast may remain the same. If the number and length of the strokes be kept up, and the aperture diminished, at the same time that the capacity of the bellows admits not of enlargement, the pressure and density of blast will be increased, although no additional weight be laid on. This frequently happens in the smith's bellows when he makes an increased effort to blow after the upper cavity is full. It is much better, however, not to exert the bellows in this way when a stronger blast is required, but to produce the effect by an additional weight. A very strong blast is found to be injurious to the iron when welding heats are required, and still more so in working steel. It is much better that an increase of air, which is frequently wanted, should be furnished by increasing the aperture, supposing the power to be at the time adequate to keep up the increased supply. Bellows should therefore be so constructed that the pressure may be uniform, and not immediately under the control of the workman. When he wishes to quicken his heat, he should have the means of increasing the aperture by a circular plate turning on an axis at right angles to the length of the pipe, as seen in fig. 9. When in the position *ab*, the whole area is filled; when in that of *cd*, the air passes in its full quantity. The index being placed at any intermediate points *ef*, will let in any proportionate quantity required.

The aperture might be made to change, by the increase of power upon the machine, and thus caused to regulate itself. Several simple contrivances of this kind may be applied by any one skilled in machinery.

New blowing machines.

These improvements would render the common leather bellows, of the form above given, very useful for smiths. The irregular blast occasioned by their present construction is found to be very injurious to the iron, both as to its quality and economy. This is abundantly shown in the use of some blowing machines lately invented, which have the advantage of a blast that is uniform, and at the same time much softer, being produced by a small pressure.

These blowing machines are also found to answer very well for melting cast iron, the soft blast having less tendency to destroy the carbon, and the quantity of air being compensated by increasing the aperture.

One of these machines is the invention of Mr Street, for which he took out a patent. It consists of a barrel-shaped vessel, from four to five feet in diameter, and of a length more or less proportionate to the work it has to perform.

This cylinder is supported on two bearers by the two ends of its axis, like a barrel churn. The cylinder is divided into two equal parts by a plane in the direction of its length, fitting the two ends and the upper side, water-tight, and extending downward to a small distance from the opposite side. This septum is in a perpendicular position when the cylinder is at rest. When this vessel is partly filled with water, and is made to pass through a certain space on its axis, the air which occupies the upper part of the vessel will be compressed on one side by the water, which flows from one side of the septum to the other, and will become in the same degree rarefied on the other, from a contrary cause. If, however, in this situation, a valve be made to open inwards from the atmosphere on the rarefied side, and another to open outwards on the condensed side, two equal and contrary currents will be established, one inwards and the other outwards On the returning stroke both these valves will shut, and the other two sides will be put in the same situation with the first cavities. If, now, two similar valves to the last be introduced, two similar currents will be produced. If the two valves at which the air escapes from the machine, one on each side of the septum, be made to communicate with one cavity from which a nose-pipe proceeds, while the other two valves communicate with the atmosphere, every stroke will discharge a quantity of air through the nose-pipe from one cavity, and introduce the same volume of air from the atmosphere into the other cavity. These strokes are produced by the oscillating motion of the machine, the limit of its vibrations being about a quarter of the circle, or 90°.

Blowing Machines

These alternate puffs of air are first propelled into a vessel containing water to regulate the blast. This vessel is divided into two portions by a septum, which passes from the close cover at the top nearly to the bottom. When the air is forced into the cavity, which is close at the top, it expels the water under the septum at the bottom into the open cavity, so as to keep a constant head in the latter, compressing the air in the former. From this air-chest a nose-pipe proceeds to the fire, and the air escapes from it with a uniform velocity so long as the same column of water in the chest is preserved. This description answers to the first machine of the inventor; he has since taken out a second patent, the specification of which is given in the *Repository of Arts*, vol. xxviii. p. 193. We shall here give a description of this machine, with the patentee's improvements. See Plate CVIII. figs. 1, 2, and 3.

Fig. 1 is a longitudinal section of this machine. AB is the cylinder resting upon the axis *ab* and *cd*, which are supported on the uprights *gg*. The oscillating motion is given to it by a rod working upon the pivot *p*, the other end of which is connected with a crank of such a length as to cause the cylinder to move through an arch of 90 degrees. The vessel is filled with water to the height *ws*.

The part CBD (fig. 2) is cut off from the rest of the cylinder by two planes meeting at *c*, and continuing down to the axis *x*, so as to work upon its convex surface. These planes extend the whole length of the cylinder, and are then divided transversely into three cavities GHI, as seen in fig. 1. The cavity G is for the reception of the external air, and is called by the patentee a receiving box. The cavity H is open to the atmosphere, the periphery of the cylinder being removed in that part. The cavity I is appropriated to the air which is driven out of the machine, through the valves *tt* and *qq* (fig. 3), which open alternately on each side. The cavity G is divided longitudinally in the middle, forming two cavities, *m* and *n*, fig. 2; two valves, *e* and *f*, fig. 1, open into each, one from the end of the cylinder, and the other from the cavity H. Each of the cavities *m* and *n* communicate with the body of the cylinder by the holes *hh* in the dividing planes. The cavity I has no division, as it receives the air from both sets of exit valves, which escapes at the pipe P.

The axis *av* works within the axis *ab* and *cd*, and is rendered air-tight by a stuffing-box within the latter. This axis will have the effect of remaining at rest while the cylinder is in motion, there being no other force exerted to turn it than the friction of the stuffing-box. The use of this axis is to support and turn a swing valve MV, which is made of rolled iron, strengthened by ribs connected with the axis. This valve is a plane, which would exactly sweep the interior surface of the cylinder without touching it. If the axis *vx* be held fast, the valve will retain its perpendicular position, while the cylinder performs its vibrating motion. The water would also remain at

Blowing Machines.

rest, with the exception of the motion which its friction and the compression of the air occasions. When the machine moves from D (fig. 3) till the plane DC comes very near to the surface of the water *ws*, the valves *qq* open, and a volume of air equal to the space DCS will be expelled through the cavity I (fig. 1), along the pipe P, during the time the valves in the cavity *m* (fig. 2) have opened to admit the same volume of atmospheric air on the returning stroke. The point B is carried the contrary way, by which another portion of air opens the valves *tt* to pass through the pipe P, while the same volume of air from the atmosphere enters the cavity *n*, which in its turn is forced through the exit valves *tt*.

The use of the swing valve MV will now be obvious. If it did not exist, every time the air was compressed on one side the water would be depressed on that side, and the compression of the air would be limited by the increased column of water on the other side. This valve, however, prevents the water from immediately changing its situation, no more escaping from one side of the valve to the other than what can pass between the edges of the valve and the cylinder, which, in the short space of one stroke, can be only a very small quantity. This may be considered as a great improvement upon the first machine, which we have before described. The patentee further intends occasionally to give to this swing valve a contrary motion to that of the cylinder, and thus still more to increase the blast. Or, in the use of a very small blast, the valve may be left at liberty, and used merely to prevent the too great agitation of the water, which in the original machine was considered as an objection. Two of those machines are frequently used together, and worked by cranks, forming an angle of 45° with each other, to make the strong part of the blast of the one to concur with the weak part of the blast of the other.

The part I of the exit pipe PL, must be precisely to the centre of motion. The part L works in a stuffing part, or a ground socket connected with the pipe LN. The latter should communicate with a regulator, which the patentee does not describe, but recommends one of water. This may be a vessel at least of the capacity of the cylinder, inverted in a reservoir of water, and may stand near to the bottom. The pipe N is inserted into the bottom, which is now uppermost. The height of the water in the reservoir must be such as to give the required pressure to the air.

When the air is forced into the inverted vessel by the machinery, the water descends in this, and rises in the reservoir, which now gives a pressure to the contained air equal to the difference of the height of the water in the inverted vessel and the reservoir. The surface of the reservoir should be the greatest possible, in order that it may be raised in the least degree by the water coming from the inverted vessel, which will have the effect of keeping the blast more uniform.

The water regulator is certainly the best for smiths' bellows, for refineries, forges, and perhaps the common melting furnace, but they have been found very objectionable in the blowing of large blast-furnaces. The air in the common blowing engine undergoes a great increase of temperature during its passage through the machine, often as much as 40 or 50 degrees. The heated air has the effect of carrying a greater quantity of water along with it into the furnace, which destroys a larger quantity of carbon than the same bulk of common air, without producing an adequate portion of heat. A great part of the heat of the air is doubtless produced by the friction of the piston of the blowing cylinder, which, in this construction, has a very tight wading. In the blowing machine above described, the water would doubtless be an objection in blast-furnaces, but, as its little friction would not heat the air like the common blowing cylinder used in blast furnaces, the objection would be less formidable. Air must doubtless give out some heat by its decrease of volume, just as it will absorb the heat by rarefaction, as is experienced in exhausting the receiver of an air-pump. The converse of this is equally shown in the little instrument employed to kindle tinder by condensing the air within it.

Blowing Machines.

The heat by the friction of this piston is probably much more than by the condensation of the air; the latter is obviated in the machine above described, and in another blowing machine lately introduced, of which we shall give a description.

This machine, in its general appearance, does not seem to have any advantage over the common blowing cylinder, but in practice it is found superior.

It resembles in some degree the common smith's bellows of the Chinese, which consists of a square wooden trunk, in the form of a parallelopipedon. A board is made to fit pretty nearly its cross section, to which is attached a long rod, by which the board is pushed backwards and forwards like a piston. At one end of the trunk is a valve opening inwards to admit air, and at the same end is a pipe with a valve opening outwards.

The machine above alluded to as having some resemblance to this, is the invention of a Mr Vaughan, who has fitted up several of them for founderies, and they are much approved. The writer of this article took a drawing from one of these machines employed to melt cast-iron at the Phœnix Foundery in Sheffield.

Figs. 6 and 7 are two views of the machine. ABCD is a square box formed of pieces of cast-metal, screwed together by hinges. Two of these are placed side by side, as may be seen in the end view, fig. 7. MQ is a piston fitting the square box, which is drawn backward and forward by the rod EF, which works horizontally on the wheels *wx* by the spear G, which communicates with the crank of a wheel at a distance.

The piston MQ, which is the most ingenious part of this machine, is enlarged in fig. 8, to render it clearer. The body of the piston is a cast-iron plate about half an inch thick, with a socket in the middle to receive the rod. The diameter of this plate is about one fourth of an inch less than that of the box. Two pieces of wood, *v n*, are cut diagonally, in order to place the pieces of leather, *l l*, between them. These leathers, with the wood, are firmly fastened to the plate by bolts, such as *gh*.

The leathers extend about two inches beyond the wood; and their slight elasticity keeps them in contact with the metallic surface, which is not required to be very smooth. When the piston moves towards the end of the box, to which the leather projects, the leather claps close to the surface, rendering it air-tight, while the leather on the other side of the piston becomes loose, and has no friction. These leathers will be contrarily acted upon when the piston acts the contrary way. The projecting curved pipes HI form a communication between the box where the piston works and the air-chest N. When the piston moves from B to D, the valves F and V open, while L and S are shut. The air contained in the box is now forced through the valve R into the chest N, and from thence along the blast-pipe P.

In the returning stroke, which is the whole length of the box, the valves R, V, and K, are shut, while L and S open. The air is forced through H to N, and then through P.

Two of these work at the same time by two cranks, which cause one to be in full blast at the time the other is returning the stroke; so that, with due management,

Blubber || Blücher.

the four puffs produced by two double strokes may be made to succeed each other at equal intervals, which almost amounts to a steady blast. The inventor recommends four of these boxes all to work together, which would produce eight puffs in the time of one double stroke, which, if divided into equal intervals, would produce a sufficiently uniform blast for any purpose.

When the leathers of the piston are rubbed with black lead, the friction amounts to almost nothing. The leather acts so easy to the surface, and is so flexible, that it may be very easily raised with the fingers. This could not be the case if it were applied in the same way in a cylinder; and this is a sufficient reason for using the square box instead of the cylinder.

This machine makes 70 strokes in one minute; the nose-pipe, where the blast enters the furnace, is $2\frac{1}{2}$ inches in diameter. When the length of stroke is the greatest, at the above speed, it furnishes about 1200 cubic feet per minute.

This machine steers clear of the objection of the water, and, from its small friction, will have less tendency to heat the air. Its original cost is also less than any other machine yet constructed. In the situations where it has been adopted it gives the highest satisfaction. The first construction of Street's bellows, above described, was only fitted for some smiths' fires, where a very soft blast was required. In their improved state they may be employed for most purposes.

All the calculations relative to bellows will be easily made, by the following rules and formula:

First, get the space or capacity formed by one stroke of the machine; call this c, cubic feet.

Then get the number of strokes per minute, which call n.

The area of the nose-pipe, in feet, call a.

The pressure on the air to be discharged, whether by a column of water or by a weight, call p.

v = the velocity with which the air escapes.

r = the resistance, in pounds, which the blast will give.

Then $cn = q$, the quantity discharged in one minute, and $v = \frac{cn}{a}$ in one minute, or $= \frac{cn}{60\,a}$ for one second.

Then, since the resistance is equal to a column of the fluid of the area a, and twice the height to give the velocity, $\frac{v^2 a}{32 \times 14} = p$; the weight of 14 cubic feet of air being equal to one pound.

The energy of air in blowing fires is as the quantity, and inversely as the space it occupies. For if the same quantity of air be consumed in half the space, the intensity of the heat, or the temperature of that particular place, will be double. Hence it is found that the same quantity of air, by weight, in winter will produce a greater effect on a blast-furnace than in summer, merely from the difference of density. The great difference in produce of iron in the cold and hot seasons of the year is a fact notorious to iron-masters. For a description of the more recent and improved method of blowing, see Iron-making, and Smelting. (C. S—R.)

BLUBBER, the fat of whales and other large sea-animals, from which train-oil is extracted. It is properly the *adeps* of the animal, and lies immediately under the skin. In the whale its thickness is ordinarily six inches, but about the under lip it is found two or three feet thick. The quantity yielded by one of these animals usually amounts to from 20 to 30 tons of blubber, yielding from 15 to 22 tons of oil.

BLÜCHER, Lebrecht von, field-marshal of the Prussian armies, Prince of Wahlstadt in Silesia, was born at Rostock in 1742. In his fourteenth year he entered into the service of Sweden; and in the war between that power and Prussia he was taken prisoner. He afterwards entered into the service of Prussia, in which he became distinguished by his activity; but conceiving himself neglected by the great Frederick, he became a farmer in Silesia, and by his enterprise and perseverance in fifteeen years he acquired an honourable independence. On the accession of Frederick-William II., he was recalled to the military service, and replaced as major in his old regiment, the Black Hussars, where he distinguished himself in six general actions against the French, rose to the rank of colonel and major-general in 1793–4, and gained a great reputation by his energy, promptitude, and foresight. He was in a subordinate command in the disastrous battle of Jena in 1802; but he made a masterly retreat with his column to Lubeck; and extorted the praises of his adversaries, who testified on his capitulation that it was caused by "want of provisions and ammunition." He was soon exchanged for General Victor, and was actively employed in Pomerania, at Berlin, and at Königsberg, until the conclusion of the war. When Prussia shook off the French yoke in 1813, he first obtained a separate command; and at the head of 60,000 troops, chiefly composed of raw militia, he defeated four French marshals at Catsbach; and rapidly crossing the Elbe, materially contributed to the signal victory of Leipzig. In several severe actions he fought his way to Paris, which he entered on 31st March 1814; where it has been stated, that but for the intervention of the other allied commanders, he was disposed to make a severe retaliation for the calamities that Prussia had suffered from the armies of France. Blowing up the *Bridge of Jena* over the Seine, was said to be one of his contemplated acts. When war again broke out in 1815, the veteran was at the head of the Prussian armies in Belgium, and exhibited his wonted enterprise and activity. But partly owing to his own confidence and temerity, partly to the skilful strategy of his celebrated opponent, he was defeated in the severe battle of Ligny on 16th of June; yet, with his characteristic spirit and energy, Blücher rallied his defeated forces, and appeared on the field of Waterloo on the 18th, just as Wellington had repulsed the last attack of Napoleon on the British position. At that critical moment Blücher was seen emerging from the wood of Frichemont on the French right; and the simultaneous irresistible charge of the British forces converted the retreat of the French column into a tumultuous flight, followed by that of the mighty victor on a hundred well-fought fields. The allied commanders met at a chateau called La Belle Alliance. The pursuit was continued through the night by sixteen fresh Prussian regiments with terrible carnage. The allies soon again entered Paris, where Blücher remained for several months; but the health of the aged commander having declined, he retired to his Silesian residence at Kirblowitz, where he died on the 12th of September 1819, aged seventy-seven. (T. S. T.)

Blue || Blueing.

BLUE, one of the seven colours into which the ray of light is decomposed when refracted through a glass prism. See Chromatics.

Blue-John, a name applied by the Derbyshire miners to the massive variety of fluorspar from the Odin mine near Castleton, which is fabricated into vases and other ornaments.

Blue Vitriol, the sulphate of copper; a salt of a fine blue or bluish-green colour, containing 32·13 per cent. of copper, 31·57 of sulphuric acid, and 36·30 of water. It is employed as an escharotic and astringent, and in the arts it is used in dyeing, cotton-printing, and the like. It owes its existence in nature to the decomposition of other minerals, particularly copper pyrites; and, after having undergone the process of purification, forms regular crystals of a blue colour. It reddens litmus paper, and is soluble in about four parts of cold and two of boiling water. Its chief localities are the Rammelsberg near Goslar, in the Hartz; Anglesea in England; and Fahlun in Sweden.

Blueing *of Metals* is the process of heating them in the

Bluff-Headed || Blumenbach.

fire till they assume a blue colour. The blueing of iron is done thus: A piece of grindstone or whetstone is rubbed hard on the work to take off the black scurf; the iron is then heated in the fire, and as it grows hot the colour changes by degrees, becoming first of a light, then of a darker gold colour, and lastly blue. Sometimes also indigo and salad-oil are ground together, and the mixture rubbed on the work with a woollen rag while it is heating, after which it is left to cool. Among sculptors is used the term blueing a figure of bronze, by which is meant the heating of it, to prepare it for the application of gold leaf; and it is so called because of the bluish cast the metal acquires in the operation.

BLUFF-HEADED, a term applied by sailors to a ship with an upright stem. It is the opposite of sharp-headed.

BLUMENBACH, JOHANN FRIEDRICH, M.D. This most distinguished man was born at Gotha on the 11th of May 1752. He studied medicine at Jena, and afterwards at Göttingen, where he took the degree of physician in 1775. His thesis on that occasion *De Generis Humani Varietate Nativa*, published in quarto, was the germ of those craniological researches to which so many of his subsequent inquiries were directed; and such was the opinion entertained of his acquirements, that he was appointed an adjunct or extraordinary professor of medicine in the following year, and ordinary professor in 1778; soon after which period he began to enrich the pages of the *Medicinische Bibliothek*, of which he was editor from 1780 to 1794, with various contributions on medicine, physiology, and anatomy. In physiology he was of the school of Haller; and was in the habit of illustrating it by comparing the animal functions of man with those of the inferior creation. He obtained a well-merited reputation by the publication of his excellent *Institutiones Physiologicæ*, a condensed, well-arranged view of the animal functions, in which the reader is supposed to be sufficiently acquainted with anatomical details to render such unnecessary. This work appeared in 1787, and between its first publication and 1821 went through many editions in Germany where it was the general text-book of the science. It was translated into English in America, by Caldwell in 1798, and in London by Elliotson in 1807.

Blumenbach was perhaps still more extensively known by his admirable *Handbuch* of Comparative Anatomy, of which the German editions were numerous, from its appearance in 1805 to 1824. It was translated into English in 1819, by our eminent surgeon Lawrence, the legitimate successor of Hunter in comparative anatomy; and again, with the latest improvements and additions, by Coulson in 1827. This Outline of Blumenbach, though slighter than the subsequent works of Cuvier, Carus, and other writers, will always be esteemed for the accuracy of his own observations, and his just appreciation of the labours of his predecessors.

One of our author's favourite works is *Decades Collectionis suæ Craniorum Diversorum Gentium*, in which accurate though slight delineations of the skulls in his noble collection are given, with brief descriptions of each. It appeared in *fasciculi*, until sixty crania were represented; exhibiting in a striking manner the peculiarities in form of the skulls of diverse nations, and justifying the division of the human race into several great varieties or families, of which five are most generally received—the Caucasian or white race, the Mongolian or Tätar, the Malayan or brown race, the Negro or black race, and the American or red race, though some have identified this race with the Mongolian.

Although the greatest part of Blumenbach's long life was passed at Göttingen, in 1789 he found leisure to visit Switzerland, and gave a curious medical topography of that country in his *Bibliothek*. He was in England in 1788 and 1792. The Prince Regent conferred on him the office of physician to the royal family in Hanover in 1816, and made him knight companion of the Guelphic order in 1821. The Royal Academy of Paris adopted him as a member in 1831. This eminent philosopher died at Göttingen on the 22d of January 1840. (T. S. T.)

Blunderbuss || Boar.

BLUNDERBUSS, a short fire-arm of a large calibre, widening towards the muzzle, and adapted for discharging many bullets at once.

BLUSHING, a sudden suffusion or redness of the cheeks, excited by a sense of shame, confusion, or surprise, or by the consciousness of some failing or imperfection, real or imaginary.

Blushing is supposed to be produced by a kind of sympathy between several parts of the body, occasioned by the same nerve being extended to them all. Thus the fifth pair of nerves being branched from the brain to the eye, ear, muscles of the lips, cheeks, palate, tongue, and nose, a thing seen or heard that is shameful covers the cheeks with blushes, driving the blood into the minute vessels there dispersed, and also affecting the eye and ear in a similar manner. For the same reason it is, that a savoury thing seen or smelled affects the glands and parts of the mouth; that if anything pleasing be heard, the muscles of the face are affected with laughter; and that if it be melancholy, it affects the glands of the eyes, and occasions weeping.

BO, a cluster of six or seven islands in the Eastern Seas, lying E.S.E. of the southern extremity of Gilolo. They are inhabited, and supply navigators with cocoa-nuts. Long. 126. 25. E. Lat. 1. 27. S.

BOA. See REPTILIA, *Index*.

BOADICEA, a valiant British queen in the time of the emperor Nero. She was the wife of Prasutagus, king of the Iceni, a people inhabiting the eastern coast of Britain. On his deathbed, A.D. 60, Prasutagus named the emperor heir to his accumulated treasures conjointly with his own two daughters, in expectation of securing thereby Nero's protection for his family and people; but he was no sooner dead than the emperor's officers seized all. Boadicea's opposition to these unjust proceedings was resented with such cruelty, that orders were given that she should be publicly whipped, and her daughters exposed to the brutality of the soldiers. The Britons took up arms, with Boadicea at their head, to shake off the Roman yoke; and the colony of Camalodunum or Colchester was taken, and the Romans were massacred wherever they could be found. The whole province of Britain would have been lost to Rome, if Suetonius Paulinus had not hastened from the Isle of Mona or Man to London, and at the head of 10,000 men engaged the Britons, who are said to have amounted to 230,000. A battle was fought with great obstinacy on both sides, and for a time with doubtful success, but at last victory inclined to the Romans. This conflict took place A.D. 62. Boadicea, who had displayed extraordinary valour, soon after despatched herself by poison. (Tac. *Ann.* xiv., *Agric.* 15–16.; Dion Cass. lxii.)

BOAR, a term in the manège. A horse is said to boar when he shoots out his nose as high as his ears, and tosses his nose in the wind.

BOAR, a male swine. See MAMMALIA.

The wild boar, among huntsmen, has several names, according to his different ages. The first year he is called *a pig of the saunder*; the second, *a hog*; the third, *a hog-steer*; and the fourth, *a boar*. When leaving the saunder, he is called a *singler* or *sangler*. The boar generally lives to the age of twenty-five or thirty years, if he escape accidents. The time of rutting is in December, and lasts about three weeks. Wild boars feed on all sorts of fruits, and on the roots of many plants. The root of fern in particular seems a favourite with them: and when they frequent places near the sea-coast, they descend to the shores, and demolish the tenderer shell-fish in very great numbers. Their general places of rest are among the thickest bushes that can be found; and they are not easily induced to break cover, but will stand at bay a long time. In April and May they sleep

more soundly than at any other time of the year; and this is therefore the successful time for taking them in the toils. When a boar is roused out of the thicket, he always leaves it, if possible, by the same way which he entered it; and when he is once up, he will never stop until he reaches some place of greater security. If a saunder of them be found together, and any of their number break away, the rest follow in the same track. When the boar is hunted in the wood where he has been bred, he can scarcely ever be brought to quit it; sometimes indeed he makes towards the sides to listen to the noise of the dogs, but he retires into the middle again, and usually dies or escapes there. When a boar happens to run a-head, he will not be stopped or put off his way by man or beast, as long as he has any strength left. He makes no doubles or crossings when chased; and, if old, utters no sound when killed, though the sows and pigs will squeak when wounded. At his full strength he is one of the most resolute and courageous of animals. His prevailing impulse is to close with his antagonist. When fairly at bay he never shrinks from any contest, however unequal; and, although mortally wounded, he will nevertheless maintain the combat with the most unflinching bravery to the last.

The hinder claws of a boar are called *guards*. In the corn he is said to *feed*; in the meadows or fallow-fields, to *rout*, *worm*, or *fern*; in a close, to *graze*. The boar is farrowed with his full complement of teeth, which afterwards increase in size, but not in number. Amongst these there are four called *tushes* or *tusks*, the two largest of which do not hurt when he strikes, but serve only to whet the other two, with which the beast defends himself, and frequently kills his assailant.

BOAT, a small open vessel, propelled on the water by oars or sails. The construction, machinery, and even the names of boats, are very different, according to the various purposes for which they are intended, and the services on which they are to be employed. Thus they are occasionally slight or strong, sharp or flat-bottomed, open or decked, plain or ornamented; as they may be designed for swiftness or burden, for deep or shallow water, for sailing in a harbour or at sea, and for convenience or pleasure. The largest boat that usually accompanies a ship is the *long-boat*, which is generally furnished with a mast and sails. Long-boats fitted for men-of-war are occasionally decked, armed, and equipped, for cruising short distances against merchant ships of the enemy, or smugglers, for impressing seamen, and other services. The *barges*, which are next in order, are longer, slighter, and narrower. They are employed to carry the principal sea-officers, as admirals and captains of ships of war, and are unfit for the open sea. *Pinnaces* exactly resemble barges, but are somewhat smaller, and have never more than eight oars; whereas a barge properly never rows less than ten. The *cutters* of a ship are broader, deeper, and shorter, than the barges and pinnaces: they are fitter for sailing, and are commonly employed in carrying stores, provisions, passengers, and the like, to and from the ship. In the structure of this sort of boat the lower edge of every plank in the side overlays the upper edge of the plank below, which is called by ship-wrights clinker-build. *Yawls* are somewhat less than cutters, nearly of the same form, and used for similar services. They are generally rowed with six oars. The above boats more particularly belong to men-of-war. Merchant-vessels above 150 tons have at least two, a long-boat and yawl. Merchant-ships employed in the Mediterranean find it more convenient to use a *launch*, which is longer, flatter in the bottom, and better adapted every way to the harbours of that sea, than a long-boat. A *wherry* is a light, sharp boat, used in a river or harbour for carrying passengers from place to place. *Punts* are a sort of oblong flat-bottomed boats, nearly resembling floating stages. They are used by ship-wrights and caulkers, for breaming, caulking, or repairing a ship's bottom. It is also the name for the smallest boat of yachts, &c. A *moses* is a very flat, broad boat, used by merchant-ships among the Caribbee Islands, to bring hogsheads of sugar off from the sea-beach to the shipping anchored in the roads. A *felucca* is a strong passage-boat used in the Mediterranean, and propelled with oars and lateen sails. The *pirogue* of the southern and eastern seas is a kind of canoe made of the trunk of a tree hollowed out. It is generally worked with paddles, but sometimes it is decked and furnished with sails and an outrigger. The *proa*, so much used by pirates in the Eastern Archipelago, is sharp at both ends, in order to sail either way. Its lee-side is rounded, but the weather-side is flat, and provided with an outrigger to secure its stability.

BOAT-BILL. See ORNITHOLOGY, *Index*.

BOATSWAIN, the officer in a ship who has the charge of the boats, sails, rigging, colours, anchors, cables, and cordage. It is also the duty of this officer to summon the crew to their duty; to assist with his mates in the necessary business of the ship; and to relieve the watch when its time expires.

He has a mate who has the charge of the long-boat, for setting forth anchors, weighing or fetching home an anchor, warping, towing, or mooring.

BOBBIN, a small cylinder of wood, with a little border or head at each end, and bored through to receive an iron pivot. It is used in spinning, to wind thread, worsted, hair, cotton, silk, gold, and silver.

BOBBING, among fishermen, a method of catching eels, different from sniggling. To bob for eels, a number of large lobs are well scoured, and a twisted silk thread is run through them from end to end with a needle: they are then tied fast with the two ends of the silk thread, that they may hang in so many hanks; after which the whole mass is attached to a strong cord, with a plummet fixed a little above the worms to sink the bait, and the cord is made fast to a strong pole. This apparatus is thrown into muddy water: the eels tug lustily at the bait; the rope is then to be drawn in gently, and the eels are brought ashore.

BOBLINGEN, a town of Wirtemberg, in the circle of Neckar, and capital of a bailiwick of the same name. It is situated upon the declivity of a hill, 11 miles S.W. of Stuttgardt. Pop. 3300, engaged in the manufacture of woollen goods, vinegar, beer, aquafortis, and chemicals.

BOBSTAYS, the ropes which secure the bowsprit of a ship against the upward strain.

BOCA-CHICA, the strait or entrance into the harbour of Carthagena in South America. It is defended by several forts belonging to the Spaniards, all of which were taken in 1741 by the English; who were obliged, however, to raise the siege of Carthagena a short time after.

BOCAYRENT, a town of the province of Valencia, in Spain. It contains 4074 inhabitants, who are remarkable for their industry in the manufacture of linen and woollens, of cordage, soap, paper, and brandy.

BOCCACIO, or BOCCAGE, GIOVANNI, one of the most gifted and learned writers of his age, whose name alone, according to Mazzuchelli, is worth a thousand eulogiums, was born in 1313. His father was a merchant at Florence, where the pursuits of commerce were held in the highest estimation. His family came originally from Certaldo, a village situated about 20 miles from the capital of Tuscany; for which reason he generally subjoined to his name the words *da Certaldo*. Boccacio was not, therefore, the son of a peasant, as has been asserted in the *Dictionnaire Historique*. He appears to have been the illegitimate offspring of a connection which his father had formed while at Paris, having been called thither by some commercial affairs; and it was in the French capital that the illustrious author of the *Decameron* first saw the light. Conveyed at an early period to Florence, he commenced his studies, and, from his tenderest years, evinced a decided taste for poetry; but he had scarcely attained

 the age of ten when his father placed him in the house of another merchant, with the view of training him up to commerce. Several years afterwards this merchant took him to Paris, and kept him in all six years in his house; but failing to inspire his charge with a taste for the mercantile profession, to which the latter gave only a reluctant and compulsory attention, he sent the youth back to his father. At Florence, as at Paris, Boccacio was divided between occupations for which he felt nothing but repugnance, and a taste for letters which went on increasing daily. And this taste received a fresh stimulus at Naples, to which he had been sent with the view of withdrawing him from such pursuits, and attaching him definitively to the mercantile profession. He remained there eight years, and instead of associating only with merchants, he established an intimacy with several learned men, Florentine as well as Neapolitan, whom the favour of King Robert, the friend and patron of letters, had drawn to his capital. There is no evidence whatever of Boccacio having personally experienced the kindness of Robert; but he appears to have excited a tender interest in the bosom of the king's natural daughter, for whom he composed several works both in prose and verse, and whom he often designates by the name of Fiammetta. Endowed with all exterior advantages, of a lively and joyous disposition, possessing an amiable and yielding character, and the favoured lover of the daughter of a king, it is not surprising that he should have then felt less inclination than ever for mercantile occupations and pursuits. The sprightly taste of the princess, the intimate companionship of men of letters, the impression made upon him in a walk near Naples by the tomb of Virgil, the presence of Petrarch, who was treated with the most marked distinction by the court, being then about to proceed to Rome, there to receive the laurel crown, and probably, also, his first intercourse with this celebrated man, whose intimate friend and associate he was afterwards to become,—all contributed to strengthen his natural inclination, and to decide his vocation as a literary man and a poet.

After a residence of two years with his father at Florence, he returned to Naples, and was favourably received by the queen, Jane; and it is believed that it was as much to gratify the young queen as his dear Fiammetta, that he began the Decameron, or collection of a hundred tales, which places him, without a rival, in the first rank of Italian prose-writers. Having lost his father, and being thus at liberty to follow his own inclination, he went to settle at Florence, where his studies suffered no interruption except what was occasioned by pleasure, and some honourable missions with which he was charged by his fellow-citizens. Among other offices of this kind, he was the person selected to go to Padua, and carry to Petrarch the intelligence of his recall, and of the restitution that had been made of the property of his father, who, formerly banished from Florence, had since died in exile; and it was in the execution of this mission that he formed with his illustrious contemporary that close and intimate friendship which only ceased with their lives. Some years afterwards, having involved himself in embarrassments by his expenditure in the purchase of books and his taste for pleasure, he was generously relieved by Petrarch, who not only afforded him pecuniary aid, but gave him good counsel both as to his works and his conduct, and was mainly instrumental in bringing about the change which subsequently took place in his habits and character. A course of pleasure or dissipation is sure, sooner or later, to terminate in satiety, ennui, heart-sickness, and remorse; and when this crisis actually comes on, the presence and counsels of a tender and judicious friend may not only serve to check the moral re-action before it proceeds too far, but may also give a new and salutary direction to the mind and feelings of the penitent. Petrarch performed this important office to his friend. The exhortations of a Carthusian monk had at first inspired the latter with an extravagant scheme of reform, being nothing less than an entire renunciation of the world, and of those studies which are denominated profane; but Petrarch brought him back to better views, and kept him steadily in that just medium which is the position recommended by true wisdom.

Some new troubles having about this time broken out in Florence, Boccacio withdrew to Certaldo, where he possessed a small estate, in order to continue his pursuits in tranquillity. Hitherto he had only written in the vulgar tongue, and produced works of mere amusement; but now he composed several, which he wrote in Latin, on subjects of erudition and history; and one of these treatises is the first modern work in which a collection was made of all the mythological notions which are scattered throughout the writings of the ancients. He knew Greek very well, having brought, at his own expense, from Venice to Florence, Leontius Pilatus of Thessalonica, and entertained him for three years, in order to learn of him that language, to read with the learned refugee the Iliad and the Odyssey, and to translate both from beginning to end into Latin. He had also the glory of procuring from Greece, at his own expense, copies of these immortal works; nor did his zeal in the cause of classical learning stop here; for he spared neither pains nor expense in order to obtain good Greek and Latin manuscripts, and employed all his influence to induce his contemporaries to learn Greek, and to substitute the study of antiquity for that of the scholastic sciences, which alone had hitherto been encouraged. Auspicious for the cause of true learning, these efforts added to the reputation and authority of Boccacio. He was twice charged with important embassies from the republic of Florence to Pope Urban V., and executed them in a manner creditable to himself and satisfactory to his countrymen. He then returned to Certaldo, and resumed his favourite studies; but a long and grievous malady, with which he was now attacked, reduced him to a state of languor and depression more painful than even the disease itself. On recovering somewhat, he undertook a difficult, but to him most agreeable, task. He had always been an ardent admirer of Dante; he knew by heart nearly the whole of his poem, and had copied it several times with his own hand. The Florentines, who had persecuted and exiled this great poet, wishing now to honour and vindicate his memory, instituted, by a decree of the senate, a public chair for the explication of this poem, which, although it contained many sublime things, was nevertheless filled with obscurities and difficulties, certain to increase with the progress of time, and in proportion as we are removed from the period in which the author wrote; and it was on Boccacio that they conferred the new professorship. But the efforts which he made to fulfil the expectations of his countrymen retarded his convalescence; the death of Petrarch, his master and friend, which took place at this time, and was suddenly communicated to him, proved a stunning blow; he became daily weaker and weaker; and in little more than a year he died at Certaldo, on the 21st December 1375, in the sixty-second year of his age.

Boccacio was indeed born a poet; he was so in all his works of imagination, at least in invention if not in style. All that he has written in verse is mediocre; several of his Italian works in prose are also poor enough. He is only superior and inimitable in his novels, of which nevertheless he made small account. Like his master Petrarch, he believed that his serious works, written in Latin, formed his best title to fame; yet his reputation rests exclu-

Boccacio. sively on a simple collection of tales, as that of Petrarch does on his amatory verses. Every thing he has written in Latin bears a character of crude precipitation, which, however, is less the effect of negligence in the author, than of those difficulties and obstacles which were then opposed to the composition of such works. In his youth he had flattered himself with the idea of obtaining the second place in poetry by his verses; his admiration of Dante did not allow him to aspire to the first; and the Italian poems of Petrarch were as yet unknown to him. But as soon as he became acquainted with the latter, he threw into the fire the greater part of his lyric verses, sonnets, canzoni, and other amatory poems; and those which have since been published are merely such as, in spite of himself, escaped this act of severity. But the fortunate result of his disgust with his poetical productions was to induce Boccacio to write with greater care in prose, and to give to his language a perfection, rhythm, harmony, and elegance in the *tournure* of expression, which it had hitherto wanted, and which Italian, with all its capabilities, has never attained to the same degree in the hands of any other writer. His style may be characterized in two words; it is *simplex munditiis;* grace, elegance, and simplicity combined are its peculiar attributes; and so skilfully is the art of the writer concealed in the very perfection of his work, that while the charm diffused over it proves irresistible to readers of every class, it seems a spontaneous emanation of his mind, the result of mere volition, without labour, without effort, and without premeditation. The following is a tolerably correct list of the works of Boccacio:

1. *De Genealogia Deorum libri* xv. *De Montium, Sylvarum, Lacuum, Fluviorum, et Marium nominibus, liber.* The first edition of these two works united is in folio, without date, but it is supposed to have been printed at Venice prior to 1472, which is the date of the second edition. A third was printed the following year, and there have since been several at Venice, Paris, and Basel. The treatise on the *Genealogy of the Gods* was the fruit of immense reading; and as there existed at that time no similar work in which information might be obtained respecting the mythology of the ancients, its success was prodigious. In this production Boccacio cites several authors no longer extant, and derives from them particulars which are only to be found in his book. This work, translated into Italian by Joseph Betusi, has gone through twelve or thirteen editions, the first being that of Venice, 1574, in 4to. There are also two French translations; the first at Paris in 1498, in folio, reprinted in 1531, also in folio, and the second at Paris in 1578, in 8vo. The little *Treatise on Mountains, Forests, Lakes, Rivers, and Seas,* has also been translated into Italian; it is in quarto, but without date or name of place.

2. *De Casibus Virorum et Fœminarum Illustrium, libri* ix. The Paris edition of this treatise is in folio, and dated 1535, 1544. It was translated into Italian by Betusi, Venice, 1545, 8vo; into English by John Ludgate, London, 1494, folio, reprinted in the same form in 1527; into Spanish by D. Pedro Lopez de Ayala, and D. Juan de Zamora, Seville, 1495, Toledo, 1511, folio; into German by Jerome Ziegler, Augsburg, 1545, folio; and several times into French, first by an anonymous translator, Bruges, 1476, folio; next by Laurens du Premier-fait, Paris, 1483, folio, and at Lyons the same year; and, lastly, by Claude Witard, Paris, 1578, 8vo.

3. *De Claris Mulieribus.* The first edition is without date or name of place; the second was published at Ulm in 1473, and, like the first, is in folio. The work was translated into Italian by Vincent Bagli, a Florentine, Venice, 1506, 4to, and by Joseph Betusi, who made several additions, and prefixed a life of Boccacio, Venice, 1545 and 1547, 8vo. There are also Spanish, French, and German versions. Boccacio.

4. *Eclogæ.* These eclogues, sixteen in number, were printed, along with those of Virgil, Calphurnius, Nemesianus, Petrarch, and Gauricus, at Florence in 1504, and again at Basel in 1546, in the *Bucolicorum Autores.*

5. *La Teseide,* the first Italian poem which presents a specimen of the epopee. It is written in the *ottava rima,* of which Boccacio is usually considered as the inventor. Ferrara, 1475, folio; Venice, 1528, 4to; Paris, 1597, 12mo, a French translation.

6. *Amorosa Visione,* Milan 1520 and 1521, in 4to, with grammatical observations, and a defence of Boccacio by Claricio d'Imola, Venice, 1531, 8vo.

7. *Il Filostrato,* a romantic poem in *ottava rima,* the hero of which is the young Troilus, son of Priam, and the subject his amours with Chryseis, whom the poet makes the daughter of Chalcas, Bologna, 1498, 4to; Milan, 1499, 4to; Venice, 1501 and 1528, 4to.

8. *Nimfale Fiesolano,* a poem also in the *ottava rima,* in which, under the veil of pastoral fiction, Boccacio is supposed to give an account of a gallant adventure which occurred at Florence in his time. Venice, 1477, 4to; Paris, Molini, 1778, 8vo.

9. *Rime,* or poems on various subjects, being such as escaped the flames when the author resolved to burn all his verses. They have been several times collected; but Baldelli's edition, printed at Leghorn in 1802, is the best.

10. *Il Filocopo, ovvero Amorosa Fatica,* &c. a romance, written by the author when very young, and wholly devoid of interest. It is unconscionably long, and desperately tedious; and the style, which is sometimes flat and at other times bombastical, gives no promise of that purity of diction which Boccacio afterwards attained. Venice, 1472, folio; Milan, 1476 and 1478, folio; Venice, 1514, 4to; Paris, 1542, folio, and 1555, 8vo.

11. *L'Amorosa Fiammetta,* another romance, in no degree superior to *Il Filostrato.* Padua, 1472, 4to; Venice, 1481, 4to; Paris, 1585, 1609, 12mo.

12. *L'Urbano,* Florence, 1598, 8vo; translated into French under the title of *Urbain le Mescogneu,* Lyons, without date.

13. *Ameto* or *Nimfale d'Ameto,* a work written in prose, intermixed with verse, and the earliest specimen of this kind of composition. Rome and Venice, 1478, 4to; Treviso, 1479, 4to; Venice, 1503, folio; Florence, 1521, 8vo.

14. *Il Corbaccio, o sia Laberinto d'Amore,* a bitter and coarse invective against some female who had displeased him after his return to Florence. The indecency of this production is abominable, but the purity and beauty of the style have caused it to be sought after. Florence, 1487, 4to; Venice, 1516, 24to, and 1528, 8vo; Paris, 1569, 8vo.

15. *Origine, Vita et Costumi di Dante Alighieri,* Rome, 1544, 8vo; Florence, 1576, 8vo. In this life of Dante Boccacio shows himself more of a romancer than a biographer; but it is nevertheless interesting on account of several curious anecdotes it contains, and also by reason of the style, which is every way worthy of Boccacio.

16. *Commento sopra la Commedia di Dante Alighieri,* an invaluable work, containing a great number of explications of difficult passages in Dante, although almost suffocated by a multitude of details foreign to the intelligence of the text. This commentary, which embodies the lessons delivered publicly by Boccacio at Florence, when he was attacked with the malady of which he died, was not printed till the eighteenth century. It extends only to the 17th chapter of the *Inferno,* and occupies the two last volumes of the collection of Boccacio's works in Italian prose, published at Naples, with the false imprint of Florence, in 6 vols. 8vo, 1724.

Boccale ‖ Boccalini.

17. Lastly, *Il Decamerone*, Boccacio's principal title to immortality, and of all works extant, that, perhaps, of which it is the most difficult to convey a tolerably accurate idea in few words. To regard it merely as a collection of gallant and licentious tales, is to entertain a very false notion indeed of this extraordinary work. The greater part of the poets, it is true, who have borrowed from this source, have indeed taken little else from it than licentiousness; but it is their fault more than that of the author, if their draughts have been so confined. In the Decameron, Boccacio has painted, as on an immense canvass, men of all conditions, of all characters, of all ages; and described events of every kind, from the freest and the gayest to the most touching and the most tragical. He has also given models of all sorts of eloquence, and carried his language to a pitch of perfection unknown before his time, and unrivalled since. For three centuries after it appeared it was constantly reprinted, and more than a hundred different editions might be enumerated, to say nothing of translations into every language of Europe which is connected with an independent literature. At the same time it has experienced singular vicissitudes. From the date of the first edition in 1470, liberties of every kind were taken with the text, particularly in the more licentious parts, which led to its prohibition by two popes, Paul IV. and Pius IV.; some academicians also undertook to reform the Decameron; important corrections as well as suppressions were made; and several editions, thus amended, appeared. But in order to judge of the work as it proceeded from the hand of Boccacio, we must revert to the older editions, or to those which have followed them. The rarest and dearest is that of Florence, 1527, in 4to. Of this, however, an exact copy was printed at Venice in 1729, but bearing at the end the name of Florence and the date of 1527. It is nevertheless easily distinguishable by those marks which are known to bibliographers. The curious ought to have, also, for comparison, the edition amended by the Florentine academicians, conformably to the orders of the grand duke of Tuscany, and approved by Gregory XIII. It will show, on the one hand, to what a state the masterpiece of Boccacio had been reduced; and, on the other, excite surprise at the remnants of the old interpolations which are preserved, and invested with the pontifical sanction. This edition was printed at Florence in 1573, in 4to. The edition of Salviati, who undertook a new reform, appeared at Venice in 1584, in 4to. In both these reformed editions, the portion of the text respected and left untouched is of extreme purity. It would be endless to attempt an enumeration of other editions, or of the translations which have been made into different languages. (*Biographie Universelle, Crescembeni.*) (J. B—E.)

BOCCALE, or BOCAL, a liquid measure used at Rome, equivalent to about an English quart.

BOCCALINI, TRAJAN, born at Loretto A.D. 1556, a celebrated satirical writer who obtained the admiration of all Italy by his refined and delicate criticisms. His profession was architecture; and it appears that he commenced rather late in life to supply the deficiencies of a neglected education. Pursuing his studies at Rome, he there acquired the friendship of several distinguished persons, and through their influence was appointed governor of a small town in the Papal States; from which, however, he was soon recalled for mal-administration. Returning to Rome, he wrote his celebrated *Ragguagli di Parnaso*, in which Apollo is represented as holding his court on Parnassus, receiving the complaints of the whole world, and distributing justice according to the exigencies of each particular case. This work, which was a satire on the lives, actions, and writings, of eminent individuals, was published at Venice, whither the author had retired, to escape, it is said, from the hostility of those whom he had abused. Here, on the 16th November 1613, Boccalini died of colic accompanied with fever, according to the register of the parochial church of Sta. Maria Formosa. His end has by some writers been related differently. They assert that as he lay in bed some ruffians, employed by the court of Spain, assailed him with small bags filled with sand, and beat him so violently that he died soon after. Mazzuchelli, however, in his *Scrittori d'Italia*, has contradicted this story. The freedom with which Boccalini had attacked the tyrannical government of Spain in his *Pietra del Paragone*, was supposed to be the cause of this outrage; but this work did not appear until two years after his death. That entitled *La Segretaria d'Apollo*, which was published as a continuation of the *Ragguagli di Parnaso*, has generally been attributed to Boccalini; but its authenticity is denied by the best critics. The titles of his works are as follows:—*Ragguagli di Parnaso*, in two centuries, Venice, 1612 and 1613, 4to; 2. *Pietra del Paragone Politico*, Cosmopoli (Amsterdam) 1615, 4to; 3. *Commentarj sopra Cornelio Tacito*, Geneva, 1669, and Amsterdam, 1677, 4to.

Boccarella ‖ Bochart.

BOCCARELLA, in the glass manufacture, a small round aperture in the furnace, beside the bocca, and almost horizontal with it. Out of this and another similar aperture the servitors take coloured or finer metal from the piling pot.

BOCCONE, PAOLO (afterwards SYLVIO), a celebrated Sicilian naturalist, born at Palermo A.D. 1633. After he had gone through the usual course of study, he was ordained priest, and entered into the Cistercian order. For the sake of improving his knowledge in natural history, he travelled over Sicily, Malta, Italy, the Low Countries, England, France, Germany, Poland, and several other countries; and in 1696 was admitted a member of the Academ. Curiosor. Naturæ, in Germany. Upon his return to Sicily, he retired to the convent of Sta. Maria d'Altifonte, near Palermo, where he died in 1704. He left many curious works, some of which have gone through several editions. The following in particular may be mentioned, 1. *Recherches et Observations Naturelles touchant le Corail, la Pierre Etoilée, et l'Embrâsement du Mont Etna*; 2. *Museo di Fisica e di Esperienza*; 3. *Osservazioni Naturali*; 4. *Della Pietra Belzuar minerale Siciliana*; 5. *Appendix ad Museum de Plantis Siculis.*

BOCHART, SAMUEL, one of the most learned men of the seventeenth century, was born at Rouen in Normandy, May 30. 1599. He early made great progress in learning, and became a proficient in the oriental languages. He was many years pastor of a Protestant church at Caen, and became tutor to Wentworth Dillon, Earl of Roscommon, author of the essay on Translated Verse. While at Caen, he particularly distinguished himself by his public disputations with Father Veron, a Jesuit, and celebrated as a polemic. The dispute was held in the castle of Caen, in the presence of a great number of Catholics and Protestants, including among the former the Duke of Longueville. In 1646, Bochart published his *Phaleg* and *Chanaan*, which are the titles of the two parts of his *Geographia Sacra*. His *Hierozoicon*, which treats of the sacred animals of Scripture, was printed at London in 1675. In 1652, Christina, queen of Sweden, invited him to Stockholm: whither he repaired accompanied by Huet. On his return to Caen he resumed his duties as a minister of the gospel, married, and was received into the academy of that city. Bochart was a man of profound erudition; he possessed a thorough knowledge of the principal oriental languages, including the Hebrew, Syriac, Chaldaic, and Arabic; and such was his zeal for extending his acquirements, that at an advanced age he wished to learn Ethiopic. He was remarkable for modesty and candour; but so absorbed was he in his favourite study, that he saw Phœnician, and nothing but Phœnician, in everything, even in the words of the Celtic; and hence the prodigious number of chimerical etymologies which swarm in his works. He died at Caen, May 16. 1667. A complete edition of his works was published at Leyden, under the title of *Sam. Bochart Opera Omnia: hoc est; Phaleg,*

Bochius || Bodin.

Chanaan, seu Geographia Sacra, et Hierozoicon, seu de Animalibus sacris Sacræ Scripturæ, et Dissertationes Variæ, 1675, 2 vols. folio; 1692, 1712, 3 vols. folio.

BOCHIUS, or BOCH, JOHN, a Latin poet, born at Brussels A.D. 1555. He travelled into Italy, Germany, Poland, and Muscovy, and at his return became secretary to the Duke of Parma. He died January 13. 1609. The critics in the Netherlands honoured him with the title of the Belgic Virgil.

BOCHNIA, the capital of a circle of the same name in the Austrian province of Galicia, is situated on the river Raba, in Long. 20. 25. E. Lat. 49. 57. 15. N. It has a gymnasium and other schools, and extensive salt mines producing annually about 200,000 cwt. of salt. Pop. 5590. This circle contains 3 cities, 9 market-towns, and 49 villages, with 204,578 inhabitants.

BOCHUM, the capital of a circle of the same name in the Prussian province of Westphalia, and government of Arnsberg, with 4877 inhabitants, engaged chiefly in the manufacture of cassimeres and hardware. The circle contains three cities, 2 market-towns, 84 villages, and 55,874 inhabitants.

BOCKING, a town and parish in the hundred of Hinckford, county of Essex, 40 miles from London. It was formerly celebrated for the manufacture of a particular description of baize, which found a ready sale in the markets of Spain; but its chief manufactures now are silk and crape. It has an old church, hospital, and flour mills. Pop. (1851) 3846.

BOCK-LAND (*book* and *land*), in ancient English law, is the same as the modern *freehold land*, held by charter or deed in writing; by which name it was distinguished from *folk-land* or copyhold land, which was holden by the common people without writing.

BODE, JOHANN ELERT, a celebrated German astronomer, born January 19. 1747, at Hamburg, where his father kept a commercial academy. From his earliest years he was devoted to the mathematical sciences, especially astronomy. In the garret of his father's house, with the aid of a telescope constructed by himself, he eagerly made observations of the heavens; and at eighteen years of age had acquired so great a knowledge of astronomy, that when Dr Reimarus visited his father, young Bode was found occupied in calculating an eclipse of the sun. This incident was the means of introducing him to the notice of Professor Büsch, who at once afforded him every facility for prosecuting his labours with success. Shortly afterwards Bode gave the first public proof of his knowledge by a short work on the solar eclipse of August 5. 1766; and this was followed by his *Anleitung zur Kenntniss des gestirnten Himmels*, an elementary treatise on astronomy, which was eminently successful, and has since gone through numerous editions. In 1772, being called to Berlin by Frederic II., he was made astronomer to the Academy of Sciences, and afterwards a member of that institution. The well-known periodical work entitled *Astronomische Jahrbücher*, which is continued to the present day, was commenced by Bode in 1774; but that on which his fame chiefly rests is the *Uranographia*, published in 1801, in which the industrious author has given observations of 17,240 stars, or 12,000 more than are to be found in any older charts. This veteran observer, who may justly be said to have been the first to diffuse a general taste for astronomy in Germany, died at Berlin, Nov. 23. 1826.

BODERIA, or BODOTRIA, the ancient name of the Firth of Forth, Scotland.

BODIN, JEAN, characterized by Bayle as "one of the ablest men that appeared in France in the sixteenth century," and famous as the author of *The Republic*, and the *Methodus ad Facilem Historiarum Cognitionem*, was born at Angers about the year 1530. He was at one time in great favour with Henry III., but this was not of long continuance. The Duke of Alençon, however, gave him several employments, and took him to England as one of his suite, where he had the pleasure of finding his *Republic* in use as a text-book in the university of Cambridge. In the *Ragguaglia* of Boccalini he is condemned to the fire as an atheist, for maintaining liberty of conscience. He declared himself with much freedom against those who asserted that the authority of monarchs is unlimited; and yet he displeased the republicans. Upon the death of the Duke of Alençon, Bodin retired to Laon, where he married; and in the time of Charles IX. he was the king's solicitor, with a commission for the forests of Normandy. He died of the plague, at Laon, in 1596. Besides his *Methodus*, and *Six Livres de la Republique*, which Laharpe has described as containing the germ of the *Spirit of Laws*, Bodin wrote *Commentaire sur les Livres de la Chasse d'Oppien*, Paris, 1555, in 4to; *Démonomanie*, Paris, 1581, in 4to; *Fléau des Démons et Sorciers*, 1616, in 8vo; *Universæ Naturæ Theatrum*, Lyons, 1596, in 8vo; *Paradoxes, doctes et excellents Discours de la Vertu touchant la Fin et Souverain Bien de l'Homme*, Paris, 1604; and *Colloquium Heptaplomeron sive de abditis Rerum sublimium Arcanis*, printed for the first time in 1841, at Berlin. For some further particulars regarding Bodin, and a general estimate of his merits as a writer, see *Prelim. Dissert.* I.

Bodkin || Bodley.

BODKIN, a small instrument of steel, bone, ivory, &c., used for making holes by piercing: also a similar instrument with an eye, for drawing tape or thread through a loop, &c.

BODLE, an old Scottish copper coin, of the value of two pennies Scots, or the sixth part of an English penny.

BODLEY, SIR THOMAS, founder of the Bodleian library at Oxford, was born at Exeter A.D. 1544. When he was about twelve years of age, his father, John Bodley, on account of his Protestant principles, was obliged to leave the kingdom. He settled with his family at Geneva, and continued there till the death of Queen Mary. In that university, then in its infancy, young Bodley studied under several eminent professors. On the accession of Queen Elizabeth, he returned with his father to England, and was soon after entered of Magdalen College, Oxford. In 1563 he took the degree of bachelor of arts, and the year following was admitted a fellow of Merton College. In 1565 he read a Greek lecture in the hall of that college; took the degree of master of arts the year after; and read natural philosophy in the public schools. In 1569 he was one of the proctors of the university, and for some time after officiated as public orator. Quitting Oxford in 1576, he made the tour of Europe; and on returning to his college after four years absence, he applied himself to historical and political studies. He became gentleman-usher to Queen Elizabeth; and in 1585 he married Anne Ball, a widow lady of considerable fortune, whose father, named Carew, was of Bristol. He was soon after sent as ambassador to the king of Denmark, and several German princes. He was next despatched on a secret mission to France; and in 1588 he went as ambassador to the United Provinces. On his return to England in 1597, finding his preferment obstructed by the jarring interests of Burleigh and Essex, he retired from court, and could never afterwards be prevailed on to accept of any public employment. He now began the foundation of the Bodleian library; and soon after the accession of King James I. he received the honour of knighthood. He died at his house in London, January 28. 1612, and was buried in the choir of Merton College chapel, where a monument of black and white marble was erected to him, on which stands his effigy in a scholar's gown, surrounded with books. Sir Thomas wrote his own life to the year 1609; which, with the first draught of the Statutes, and his Letters, have been published from the originals in the Bodleian library, by Hearn, under the title of "*Reliquiæ Bodleianæ*, or Authentic Remains of Sir Thomas Bodley;" London,

Bodmin || Boehm.

1793, 8vo. For a particular account of the *Bodleian Library*, see LIBRARIES.

BODMIN, a parliamentary and municipal borough and market-town in the county of Cornwall, 235 miles from London. It is situated between two hills, and consists of one narrow and ill-paved street, nearly a mile in length. It is one of the county towns; the assizes and quarter-sessions being held here alternately with Launceston. It is also a stannary town. It has a spacious church, town-hall, lunatic asylum, county jail and a grammar-school founded by Queen Elizabeth. The principal manufacture is shoes. Its municipal affairs are conducted by a mayor, four aldermen, and twelve councillors, and it returns two members to parliament. Market-day, Saturday. Pop. (1851) of municipal borough, 4327, of parliamentary borough, 6337.

BODONI, GIAMBATISTA, superintendent of the royal press at Parma, chief printer to his Catholic Majesty, member of various academies in Italy, and knight of several orders, was born in 1740, at Saluzzo in Piedmont, where his father owned a printing establishment. While yet a boy, he began to engrave on wood. He at length went to Rome, where he became a compositor for the press of the Propaganda. He made himself acquainted with the oriental languages, and thus was enabled to render essential service to the Propaganda press, by restoring and accurately distributing the types of several oriental alphabets which had fallen into disorder. The Infante Don Ferdinand having established at Parma, about 1760, a printing-house on the model of those in Paris, Madrid, and Turin, Bodoni was placed at the head of this establishment, which he soon rendered the first of the kind in Europe. The beauty of his typography, &c., leaves nothing further to be desired; but the intrinsic value of his editions is seldom equal to their outward splendour. His Homer, however, is a truly magnificent work; and, indeed, his Greek letters are faultless imitations of the best Greek manuscript. His editions of the Greek, Latin, Italian, and French classics, are all highly prized for their typographical elegance, and some of them are not less remarkable for their accuracy. Bodoni died at Padua in 1813, aged seventy-three. Some years after his death appeared a magnificent work in two volumes quarto, entitled *Manuale Tipografico*, containing specimens of the vast collection of types which had belonged to this celebrated typographer.

BOECE, or BOETHIUS, HECTOR. See BOYCE, HECTOR.

BOEDROMIA (Βοηδρόμια), a festival celebrated at Athens in memory of the succour brought by Ion to the Athenians, when invaded by Eumolpus in the reign of Erectheus. Various accounts of its origin are given. Plutarch (*Thes.* 27) says that it was held in commemoration of the victory obtained by Theseus over the Amazons, in the month of Boëdromion, which was the third month of the Athenian year, corresponding to our September.

BOEHM, or BEHMEN, JACOB, founder of the sect of Boehmists, and called by his disciples the Teutonic Theosophist, was born in 1575, near Goerlitz in Upper Lausatia. He was bred a shoemaker, and for some time supported a large family by this occupation; but having dabbled in chemistry, his mind, heated by sermons and German divinity, became subject to raptures, mystical ecstacies, and notions of divine illumination. To these he first gave vent in 1612, in a treatise entitled *Aurora, or the Rising of the Sun*, a mixture of astrological, philosophical, chemical, and theological extravagances, written in a quaint and obscure style. This work was censured by the magistrates of Goerlitz, who at the instigation of the clergy endeavoured to suppress it; yet Boehm continued to dream and to scribble, and in 1619 published his treatise *De Tribus Principiis*, inculcating a species of Spinozism, namely, that the operations of grace are subjected to laws analogous to those which nature has imposed in the purification of metals, and that God is to be regarded as the substance of the universe, which has produced everything by way of emanation. He afterwards went to Dresden, where he was examined by some theologians more indulgent than those of Goerlitz, and found irreproachable. He died at Goerlitz in 1624, leaving a great number of treatises *On the Celestial and Terrestrial Mystery, and on the Intellectual Life.* "It is not possible," says Mosheim, "to find greater obscurity than there is in these pitiable writings, which exhibit an incongruous mixture of chemical terms, mystical jargon, and absurd visions." Nevertheless, in the last century, Boehm found a zealous apologist in William Law, the pious author of *Christian Perfection*, who published an English translation of his work, in two vols. 4to. Boehm had a great many disciples, some of whom, like Kuhlmann, who was burned at Moscow in 1684, were wild and dangerous fanatics. All his works were collected and reprinted at Amsterdam in 1682, and again in 1730, under the title of *Theosophia Revelata.*

Bœotia.

BŒOTIA (Βοιωτία), a country of central Greece, bounded in the south by the Gulf of Corinth, by Magaris and Attica; in the east by Attica and the Euripus; in the north by the Locri Opuntii; and in the west by Phocis. Its surface is calculated to amount to about 1119 English square miles. The country, surrounded nearly on all sides by mountains, divides itself naturally into three parts, the low country of and about Lake Copais, the valley of the river Asopus, and the coast district between mount Helicon and the Corinthian gulf. The country about Lake Copais is a large valley, so completely surrounded by hills that it is connected with the Euboean Sea only by subterraneous passages. The extensive Lake Copais in this hollow is fed by the Cephisus, the principal river of the country. The natural subterraneous passages not being sufficient to carry off the great masses of water accumulating at times in the valley, the early inhabitants often suffered severely from inundations; whence at a very remote period cloacæ were built, probably by the Minyans of Orchomenos, to carry off the waters. Remains of these works, as great and stupendous as any that were executed in antiquity, still excite the admiration of the traveller, and for thousands of years they made that part of Bœotia one of the most fertile districts of Greece. For several centuries, however, these drains have been neglected, in consequence of which the country has been changed into a pestilential marsh. Between this valley and the basin of the Asopus is situated the Theban plain, which is still distinguished for its fertility. The lowlands and valleys of Bœotia were notorious in antiquity for their moist and thick atmosphere, which was believed to exercise a peculiar influence upon the character of the inhabitants, for they are often spoken of as remarkable for dulness, and a kind of intellectual insensibility. The dialect spoken by the Bœotians was a broad Æolic.

In the earliest times Bœotia was inhabited by several tribes, such as Aonians, Temmices, Hyantes, Thracians, Leleges, Phlegyans, and the Minyans of Orchomenos, the last of whom appear to have formed a great centre of civilization at a very remote period. But all these tribes were gradually either expelled by the Bœotian Æolians immigrating from Thessaly, or absorbed by them, so that in later times they wholly disappear. The country which before had had no common name, henceforth is always spoken of as Bœotia, and the several towns and cities, with Thebes at their head, formed a sort of confederation; in which, however, the Thebans and Bœotians frequently came into hostile collision, Thebes claiming the supremacy of the whole country, and the Bœotian towns insisting upon their independence. The political history of the country is inseparably connected with the history of ORCHOMENOS, THEBES, PLATÆÆ, and THESPIÆ, to which the reader must be referred for details. The Bœotian confederacy continued its nominal existence even under the Roman emperors, although the country was so reduced, that about the time of

Boerhaave.

Augustus, Tanagra and Thespiæ alone could be considered as towns, the others having been either entirely destroyed, or existing only as villages. (Compare the Travels of Clarke, Wheler, Dodwell, Sir W. Gell, Hobhouse, and Thiersch, *Etat actuel de la Grèce*, vol. i. p. 280, vol. ii. p. 23; Forchhammer, *Hellenika*, p. 143, fol.) (L. S.)

BOERHAAVE, HERMANN, one of the most celebrated physicians of modern times, was born at Woorhout near Leyden, December 31. 1668. Destined for the clerical profession, to which his father belonged, he received a liberal education, and early displayed unusual abilities. At the age of sixteen he entered the university of Leyden, where he studied under Gronovius, Ryckius, Trigland, and other distinguished men, and obtained the highest academical honours. In 1690 he took his degree in philosophy; on which occasion he delivered an inaugural dissertation *De distinctione mentis à corpore*, in which he attacked the doctrines of Epicurus, Hobbs, and Spinosa. Being left, on the death of his father, without any provision, he was compelled to support himself by teaching mathematics. By the advice of Vandenberg, the burgomaster of Leyden, Boerhaave now applied himself with ardour to the study of medicine, to which indeed he had early manifested a decided inclination. The works of Hippocrates among the ancients, and those of Sydenham among the moderns, were the especial objects of his study; but his reading was by no means confined to these authors. In 1693 he took his degree of M.D. at Harderwyck in Guelderland, and immediately entered on the duties of his profession. His merits soon became conspicuous; and in 1701 he was appointed by the university of Leyden to supply the place of Drelincourt as lecturer on the institutes of medicine. His inaugural discourse on this occasion was entitled *De commendando Hippocratis studio*, in which he recommended to his pupils that great physician as their model. In 1709, the university rewarded his distinguished merit by appointing him successor to Hotton in the chair of botany and medicine, in which capacity Boerhaave did great service, not only to his own university, but also to botanical science, by his improvements and additions to the botanic garden of Leyden, and by the publication of numerous works descriptive of new species of plants. He was appointed in 1714 rector of the university. In the same year he succeeded Bidloo in the chair of practical medicine, and in this capacity he had the merit of introducing into modern practice the system of clinical instruction. Four years later he was appointed to the chair of chemistry, and delivered an inaugural discourse, which contains the germs of his celebrated *Elements of Chemistry*. In 1728 he was elected into the Royal Academy of Sciences of Paris, and two years later into the Royal Society of London; to both of which he communicated his chemical researches. In 1729 declining health obliged him to resign the chairs of chemistry and botany; and in 1731 he resigned the rectorship of the university, to which office he had been re-elected. On this occasion he delivered a discourse *De Honore Medici Servitute*. This great and good man died, after a lingering and painful illness, which he bore with Christian patience and firmness, on the morning of the 23d September 1738. His funeral oration was delivered by his pious and learned friend the Rev. Mr Schultens.

From the time of Hippocrates, no physician had more justly merited the esteem of his contemporaries, and the admiration of posterity, than Boerhaave. To uncommon intellectual abilities he united those amiable qualities of the heart which give them so great a value to society. His personal appearance was simple and venerable. He taught very methodically, and with great precision: his style was eloquent, and his delivery dignified and graceful. He sometimes also gave his lectures a lively turn; but his raillery was never coarse or satirical. He possessed remarkable powers of memory, and was an accomplished linguist. A declared foe to all excess, he considered decent mirth as the salt of life. He was fond of music, with which he had a scientific acquaintance; and during winter he had a weekly concert in his house. It was his daily practice throughout life, as soon as he rose in the morning, which was generally very early, to retire for an hour to private prayer, and meditation on some part of the Scriptures. He often told his friends, when they asked him how it was possible for him to go through so much fatigue, that it was this practice which gave him spirit and vigour in the business of the day.

Boerhaave.

Of his sagacity, and the wonderful penetration with which he often discovered and described, at first sight, such distempers as betray themselves by no symptoms to common eyes, very surprising accounts have been transmitted to us. Yet so far was he from having presumptuous confidence in his own abilities, or from being puffed up by prosperity, that he was condescending to all, and remarkably diligent in his profession: he used often to observe that the life of a patient, if trifled with or neglected, would one day be required at the hand of the physician. He used to say that the poor were his best patients, because God was their paymaster. His benevolence, however, was exercised with discrimination. The activity of his mind sparkled visibly in his eyes. He was always cheerful, and desirous of promoting every valuable end of conversation, of which the excellency of the Christian religion was frequently the subject. He never regarded calumny nor detraction,—for even he had his enemies,—nor in any instance thought it necessary to confute them. "They are sparks," said he, "which, if you do not blow them, will go out of themselves. The surest remedy against scandal, is to live it down by a perseverance in well-doing; and by praying to God that he would cure the distempered minds of those who traduce and injure us." His great skill and celebrity as a physician brought him a large fortune. He left his only surviving daughter two millions of florins.

The genius of Boerhaave raised the fame of the university of Leyden, especially as a school of medicine, so as to make it a resort of strangers from every part of Europe. All the princes of Europe sent him disciples, who found in this skilful professor not only an indefatigable teacher, but an affectionate guardian. When Peter the Great went to Holland in 1715, to instruct himself in maritime affairs, he also took lessons from Boerhaave. The reputation of this eminent man was not confined to Europe: a Chinese mandarin wrote him a letter directed "To the illustrious Boerhaave, physician in Europe;" and it reached him in due course. The city of Leyden raised a splendid monument to his memory in the church of St Peter, inscribed "To the salutary genius of Boerhaave," SALUTIFERO BOERHAAVII GENIO SACRUM.

When Boerhaave first directed his attention to medicine, the philosophical reform inaugurated by Bacon had given a powerful impulse to the physical sciences; and these, accordingly, occupied all minds, whilst the healing art had but little profited in consequence. It was overlooked or forgotten that, from its very origin, Hippocrates had applied to it the experimental philosophy with which the learned were now everywhere so enthusiastically occupied. His theory, however, still continued to fluctuate between several dogmas equally remote from the truth. The chemists who, at the revival of learning in Europe, had overturned the authority of Galen, had to defend themselves against the sects of the mechanicians, and of Bellini, which divided the dominion of medicine between them. In a small portion of Germany alone Stahl brought back men's minds to the judicious doctrine of Hippocrates, attributing all the movements in the animal economy to a force inherent in itself, and different from the general forces of matter; but in adopting a word, the meaning of which was by no means precise, he rendered less general and less salutary the influence which he would otherwise have produced. The first perusal of Hippocrates

Boëthius. appeared to have carried away Boerhaave; but this physician, endowed by nature with a mind fitted for analysis, comparison, and combination, rather than with a creative and inventive genius, was unable to resist the influence of his age, and above all, the effect of his early studies. Having been a mathematician and natural philosopher before he became physician, he was constantly carried away by the first objects of his labour and research; and being more capable than any one else of detecting the accessory affinities between these sciences and that of man, he ran greater risk of being seduced by them. But as every system, however vicious, has always, along with the facts which it arranges and offers to explain, a point of accordance more or less remote, he thought that the best medical system would be that which should unite and combine all opinions. Forgetting that living bodies are free during their life from those movements to which other bodies are imperiously constrained, or at least counterbalance them, and that all the acts which they perform are the result of an activity which is peculiar to them; overlooking, also, that those movements of the living economy which most easily admit an application of the laws of physics and mechanics, have, nevertheless, as a *primum mobile*, the force of life, and only receive from the forces of dead matter an accessory impulse; Boerhaave wished to combine in one and the same theory the vital philosophy of Hippocrates, the chemical principles of Sylvius, the mechanism of Bellini, and many other incongruities besides: attributing more, however, to the mechanical and chemical forces, which can never be but accessory, than to the more profound and secret powers of life, which are the principal. Thus the calibre of the vessels adjusted to the dimensions of the globules composing the liquids of the body, formed, according to him, the hydraulic relation on which depended the circulation of the humours, their separation from the blood in the different secretory organs, the morbific congestion of the blood in various fluxions, in humours, inflammations, and such like; and hence he concluded that all the efforts of the physician should be directed to establish this relation, or rather mechanical equilibrium. Nor did he stop even here. To the mechanical hypotheses just mentioned he added others founded on chemical principles, when, in attempting to explain the causes and the phenomena of diseases, he admitted the formation of pretended acrimonies in the blood, which the physician ought, according to him, to have constantly in view in order to neutralize them; acrimonies which were long famous in the language of the schools, and which are still found in that of ordinary life. The whole phenomena of diseases, with the spontaneous evacuations by which they are terminated, and which constitute the crises, find a ready explanation on this vicious system, which seems to offer a reason, when it only mystifies with a word, involving a gratuitous hypothesis. In practice, however, theory receives many modifications; and there can be little doubt, that in prescribing for patients, Boerhaave was more guided by experience and good sense than by the strangely eclectic doctrine to which we have here cursorily alluded.

The principal works of this illustrious physician are, 1. *Institutiones Medicæ*, Lugd. Bat., 1708; 2. *Aphorismi de cognoscendis et curandis Morbis*, Lugd. Bat., 1709. On this work, which was the text book of Boerhaave's lectures, Van Swieten published a commentary in 5 vols. 4to; 3. *Libellus de Materia Medica, et Remediorum Formulis quæ serviunt Aphorismus*, Lugd. Bat., 1719. 4. *Institutiones et Experimenta Chemiæ*, Paris, 1724.

BOËTHIUS, or BOËTIUS, ANICIUS MANLIUS TORQUATUS SEVERINUS, a Roman statesman and philosopher, born of an illustrious patrician family, between A.D. 470 and 475. It is conjectured that he was the grandson of Flavius Boëthius, the prefect of the prætorium, who was murdered by Valentinian III., and that his father was the consul of A.D. 487. Being left an orphan at a very early age, the care of his education devolved on his relations, who sent him, it has been said, to Athens, where he resided eighteen years, and was a pupil of Proclus. This statement, however, rests only on the very questionable authority of Thomas Brabantinus (*De Disciplina Scholarium*), and is in effect contradicted by Cassiodorus (i. 45). However this may be, he was early distinguished at Rome for the extent and variety of his acquirements, and his intimate acquaintance with the literature of Greece. Boëthius occupies a remarkable place in literary history, as standing on the confines between the ancient and scholastic philosophy; being, says Gibbon, the last of the Romans whom Cicero would have acknowledged for his countryman. He lived at Rome in great splendour and affluence, and was not more distinguished for his learning than for his virtue and great liberality to the poor. Rising rapidly in the public esteem, he was successively appointed to various high offices in the state, and at length was made consul A.D. 510. That public affairs, however, did not entirely engross his attention, is testified by his great literary industry, and in particular by his voluminous translations from the Greek philosophers. As a statesman he was pre-eminent for integrity, as well as for his unremitting diligence in the detection of fraud and the suppression of violence, to which his countrymen were continually exposed from the rapacity of their Gothic invaders. The talents and virtues of Boëthius were duly appreciated by Theodoric, who made him *magister officiorum* in his court, and consulted him upon all affairs of importance. By that king he was employed to regulate the coinage with a view to the prevention of forgery; and he was engaged in some important negotiations with Gundebald, king of the Burgundians, and with Clovis, king of the Franks. He also appears to have paid some attention to practical mechanics, as among other specimens of his skill he constructed for Gundebald a clepsydra and a gnomon, which greatly delighted that prince. Boëthius.

Boëthius married Rusticiana, the daughter of Symmachus, and by her he had two sons, who were made consuls A.D. 522; upon which occasion, after pronouncing a panegyric on Theodoric, he distributed among the populace a large sum of money. The consulships of his sons, and that of his father, have erroneously been ascribed to himself. The story also of his previous marriage with Elpis of Sicily appears to be a fable, as the two sons of that lady were consuls in the year 500, at which time Boëthius was certainly not above thirty years of age.

His unflinching integrity, and the zeal he displayed in defending his countrymen against the extortion and excesses of their Gothic masters, rendered Boëthius highly obnoxious to the courtiers; and they resolved to accomplish his ruin. Theodoric, now grown through old age morose and fretful, lent a ready ear to their insinuations against his noble minister; and of this disposition in the king, three men of profligate lives and desperate fortunes, Gaudentius, Opilio, and Basilius, took advantage in order to gratify private revenge. The boldness with which Boëthius defended Albinus when accused of treason, was made the plea on which they charged him with a design to dethrone the king and throw off the barbarian yoke; to which was added the crime of sacrilege or sorcery. Boëthius was at this time at a distance from Rome; yet Theodoric transmitted the complaint to the senate, who, partly perhaps through fear, condemned him to death without summoning him to his defence. Accordingly he was imprisoned at Ticinum (Pavia), in the baptistery of the church; and here, during his captivity, he composed his celebrated treatise *De Consolatione Philosophiæ*. The manner of his death is uncertain: it has been said that his eyes were forced from their sockets by a cord drawn tightly round his head, and that he was beaten with clubs till he expired; but it is more probable that he suffered decapitation, A.D. 524–526. Two centuries afterwards, a cenotaph was erected to his memory in the church of S. Pietro Cielo d'Oro, by Luitprand king of

Bog ‖ Bogotá.

the Lombards; and in 990 Otho III. honoured his memory with a magnificent mausoleum, which was inscribed with an epitaph by Pope Sylvester II.

It was for ages the custom to regard Boëthius as a Christian saint and martyr, but without any sufficient foundation; for unless the theological works sometimes ascribed to him be really his (which seems more than doubtful), there is no evidence of his having professed Christianity; nor is the name ever mentioned in the *Consolatio Philosophiæ*, though the high moral tone, and the belief in prayer and a superintending Providence, might naturally lead to such an inference. This work is written in alternate prose and verse (the latter chiefly borrowed from Seneca), and is a dialogue between the author and Philosophy personified.

During the middle ages this work had many translators as well as imitators. For centuries the Peripatetic philosophy was studied only through the commentaries of Boëthius; but on the introduction of Aristotle's writings into Europe in the thirteenth century, the fame of Boëthius, whose works had in some measure supplied the void during 800 years, gradually began to decline, and sunk at length into comparative obscurity.

The learning and eloquence of Boëthius are conspicuous in his works, which were first published in a collected form at Venice, in folio, 1491 (or 1492); and an improved edition, in folio, appeared at Basle in 1570. It is worthy of notice that Boëthius is one of the principal Latin writers on music, and that his treatise *De Musica* supplied for some centuries the want of those Greek manuscripts which were supposed to be lost. It may also be observed, as an interesting fact in literary history, that Alfred the Great translated the *Consolatio Philosophiæ* into Anglo-Saxon, with large original additions. The best edition of this work is by J. S. Cardale, with notes and a translation, 1828.

BOG, or Bog of Gight, a small town of Scotland, seated near the mouth of the river Spey, in Long. 2. 23. W. Lat. 57. 48. N.

BOGALCUND. See Rewah.

BOGNOR, a rising market and maritime town of Sussex, in the rape, and six miles S.E. of the town of Chichester. Previous to 1785, when the proprietor, Sir R. Hotham, began its improvement, it consisted of only a few huts inhabited by fishermen. It has now become a favourite watering-place, and has many handsome villas, a market-place, mechanics' institute, hotels, baths, assembly rooms, and the other accessaries of a watering-place. Pop. (1851) 1913.

BOGODUCHOW, the capital of a circle of the same name, in the European government of Charkow, on the river Merle. It contains four churches and about 7000 inhabitants. Long. 35. 45. E. Lat. 50. 10. N.

BOGOMILI, or Bogarmitæ, in *Ecclesiastical History*, a sect of heretics which sprung up about the year 1179. Their founder was one Basil, a monk, who was burnt alive at Constantinople by the Emperor Alexius Comnenus. Their system was nearly allied to that of the ancient Gnostics and Manichæans. (See Anna Comnena, *Alex.* xv.; Wolf, *Hist. Bogomilorum.*)

BOGOTÁ, formerly called Santa Fé de Bogotá, the capital of the republic of New Granada, is situated in the province of the same name, in 4. 6. N. Lat. and 78. 30. W. Long., in an elevated plain or table-land forming part of the eastern ridge of the cordillera of the Andes, which separates the extensive valley crossed by the river Magdalena from those immense plains that are watered by the Meta, the Casanare, and many other rivers flowing eastward, which increase the waters of the majestic Orinoco.

Physical aspect of the country.

The plain of Bogotá occupies a space of about 60 miles from south to north in length, and 30 miles east to west in breadth. It is surrounded by lofty mountains, but more especially to the eastward, where the summits of Chingaso and the Paramo de la Suma Paz are conspicuous for their elevation. No part of this chain, however, has been found to exceed in height 14,000 feet above the level of the sea, and consequently in these latitudes it does not reach the limits of perpetual snow. The mountains which bound it in other directions are much less elevated; and over those to the westward may be seen, in the distance, the snowy summits of the more elevated mountains which constitute the central ridge of the cordillera. Throughout its whole extent this plain exhibits evident marks, in the perfect level of its surface, the alluvial nature of the soil, and the appearance of the insulated rocks which rise up in some parts of its extent, of having formerly been the site of an extensive lake. It is traversed by the river Funza or Bogotá, which, collecting into one channel the numerous mountain-streams that water the valley, bends its course to the south-western extremity of the plain, and enters a narrow channel, from which it is precipitated over a perpendicular precipice of 600 feet in height, into the valley of the Magdalena, forming the magnificent fall of Tequendama. This splendid cataract is an object of wonder and admiration to all beholders. The fall forms one continued sheet of water, interrupted only a little at its upper part by a projecting ledge of rocks. So great is the diffusion of water in the surrounding atmosphere, in the form of rain or haze, that a perpetual humidity prevails; and the vegetation in the immediate vicinity exhibits an uncommon degree of vigour and luxuriance. The contrast of the vegetation at the summit, where oaks, elms, and other trees of temperate climes are found, with that at the bottom, where the graceful palm-tree flourishes, is very remarkable, and cannot be altogether accounted for merely by the difference of level. The evaporation at the fall must be very great, as the volume of water which issues from the bottom of the valley towards the Magdalena is much smaller than at the summit, where the river leaves the plain of Bogotá. In various parts of the plain, from the great equality of its surface, the banks of the river are to a considerable extent inundated, and so marshy, that, especially in the rainy season, they cannot be passed without difficulty. These situations abound in ducks and other water fowl, in the capture of which an ingenious device is resorted to by the Indians. His head concealed by a cap made of rushes, while the rest of his body is under water, the fowler stealthily moves towards the game, which he seizes by the feet and secures to his girdle.

Bogotá.

Could the opening at Tequendama, through which the river Bogotá now escapes, be closed up by artificial means, the whole extent of the plain would be converted into one continuous lake, as appears to have been the case in former times; for the change which has been produced, and which has rendered so great an extent of soil useful to man, has without doubt been occasioned by the agency of the river, whose waters, by constant attrition during a series of ages, have eventually been able to overcome the rocky barrier opposed to their progress, and have hollowed out the deep channel through which the river now precipitates itself into the abyss beneath; and, from our knowledge of the laws which regulate the economy of nature, we may anticipate that the same causes will in time to come still more effectually drain the plain of Bogotá. The traditions of the aborigines tend to confirm the view which is now taken of the ancient condition of this plain; but, ignorant of the extensive operation of those natural causes which are known to us, they ascribed the whole to supernatural agency, and have handed down a legend, setting forth, that an aged man of great power and wisdom, named Bochica, broke down, by means of his powerful arm, a passage through the rocks which inclose the valley at Tequendama, and formed the outlet by which he drained the adjacent plain; and that having accomplished this, he taught the inhabitants of the country to build cities and villages, and introduced among them those habits of industry, civilization, and religion, which were found to exist at the time when the country was discovered by Europeans.

This extensive plain is exceedingly fertile, and susceptible of the highest cultivation. It produces abundant crops of wheat, barley, and the leguminous plants cultivated in Europe. Of the former the average produce is five quarters per acre; and of all these, owing to the regular succession of the rainy and dry seasons, two crops may be obtained from the same field in one year; a practice, however, which is not usually followed with the cereals, as these require the alternation of green crops, to prevent the fertility of the soil becoming too much exhausted. Lucerne is also cultivated to a great extent, and affords ample sustenance to numerous flocks of sheep and herds of cattle

Bogotá. and horses, which are reared and maintained on this plain for the supply of the capital. Before the conquest of the Spaniards, the plain of Bogotá maintained a numerous population; but the inhabitants who at present reside on it, and are occupied in agricultural pursuits, are far too few in number to give full development to its fertility and resources. Its immediate vicinity to a populous city, where there is a ready market for all its produce, presents very powerful inducements to the establishment of industrious and intelligent agriculturists; and, doubtless, many such, from Europe and elsewhere, will ere long find their way to so inviting a situation.

Climate. The plain of Bogotá, according to the observations of Humboldt, has an elevation of 8694 feet above the level of the sea; and consequently, although so near the equator, it enjoys a mild and equable climate, the inhabitants experiencing a kind of perpetual spring. In consequence of the sun being twice perpendicular at nearly equidistant periods during the year, there are two winter or rainy seasons, and two summer or dry seasons every year, each of about three months continuance; the rainy season commencing about the equinoxes, and continuing during the months of March, April, and May, and again during September, October, and November; and the dry seasons beginning with the solstices, and continuing during the intermediate months. Even during the winter months the rains are not continuous, but generally the mornings are cool and exceedingly agreeable, the rain usually commencing towards the afternoon. The range of the thermometer averages at this season from 58° to 63°, but sometimes descends as low as 47° of Fahrenheit. During the summer months, however, there is almost constantly a serene and unclouded sky, with so little dew during the night that it scarcely incommodes the inhabitants who then venture out into the open air. At this season the average height of the thermometer is from 68° to 70° in the shade. A climate so delicious is found very conducive to the preservation of health, and few spots within the tropics present so desirable a place of residence. Here those insects and venomous reptiles which occasion so much annoyance in the neighbouring districts of less elevation are altogether unknown; and the females who inhabit this plain possess a freshness of complexion unknown to those who dwell in less favoured parts of the country. Yet, with all these advantages, the period of human existence does not appear to be in general so long protracted in this country as in more rigorous climates; old age comes on at a less advanced period of life; and females, who reach maturity at an early age, exhibit the symptoms of decay at a period when women in England are in the full enjoyment of all their physical and intellectual faculties.

Owing to its great elevation, the rarefaction of the atmosphere is so considerable, that strangers, on their first arrival at Bogotá, are generally affected with a degree of oppression and difficulty of breathing; but this, in most instances, gradually disappears with a protracted residence. Here epidemic diseases are altogether unknown. Travellers, however, who proceed to Bogotá by the Magdalena are not unfrequently attacked, on their arrival, with intermittent fevers; but there is every reason to believe that the causes which give rise to this complaint have been in operation during the period of their navigating that river.

Minerals. The mountains which surround the table-land or plain of Bogotá, and those that extend towards the provinces of Casanare, Velez, Mariquita, and Antioquia, abound in rich mines of iron, copper, lead, silver, gold, sulphur, precious stones, and coal. Towards the north, in the province of Velez, are situated the celebrated Monriquira copper mines, which for more than a century have supplied all the interior of New Granada with that metal. As they have not yet been scientifically worked, the yield has hitherto been much smaller than it ought to have been. They are very extensive, and in the immediate vicinity are abundant coal mines, which hitherto have not been worked by the proprietors, as the abundance of other fuel has hitherto obviated the want of them. The copper mines of Monriquira are situated at a distance of 45 miles from the river Carare, which is one of the navigable streams flowing into the Magdalena; and the authorities of Velez are occupied in opening a road leading to that river by which to export the rich produce of their province. The copper mineral of Monriquira assayed at Swansea, produced 31 per cent. of pure copper, and a small quantity of silver. When science shall be applied to the working of these mines, and a sufficient number of workmen employed, they will be able to supply not only the whole of New Granada, but also contribute a considerable quantity for exportation. In Villete, a hamlet situated halfway between Bogotá and the river Magdalena, there are also some rich copper mines not yet worked: the most noted of these are those of Poyandé, on the left bank of the river Magdalena to the south-east of Bogotá. These mines, from their proximity to the river Magdalena, which is the principal source of communication in New Granada, offer the greatest advantages for working, and have been lately undertaken by a New Granadian house. Bogotá.

Westward of Bogotá is the province of Mariquita, and on the left bank of the Magdalena are the silver mines of Santa Anna, now worked by an English company called the Mariquita and New Granada Company. The hilly range in which these mines are situated abounds in gold mines as they approach the province of Antioquia, which comprises auriferous grounds of extraordinary richness, and have lately attracted the attention of Europe. Several companies for working the mines have been formed in consequence. In the auriferous parts of Antioquia, works have lately been constructed by the New Granada Company, formed in this country, and possessing the rich mines of Frontino, Bolivia, and Juan Creollo; as also by a French company working the mines of Curazao on the right bank of the river Nare, and by a multitude of national companies, who are daily making new discoveries.

The produce of the gold mines of Antioquia at the present time is calculated at five millions of dollars annually, although only a small part of the population work them, as the inhabitants generally prefer agriculture to mining.

Thus it is that although the population of Antioquia, at present divided in three provinces, is 230,000, it is calculated that not more than 7000 work in the mines.

In the vicinity of Bogotá are the abundant salt mines of Zipaquira, Enemocon, and Tauza. From these and from the salt pits of Cheta, Recetor, Pajarito, and Cumaral, the whole of the interior of New Granada is supplied.

These salt mines were worked by the Spanish and Columbian governments by the primitive method which they found in use among the Indians. But the government of New Granada has established a perfect administration for scientific and economical working, by which they produce considerable quantities.

At the present time these salt mines yield to the government an income of half a million dollars annually. As the population increases the revenue to the government will be augmented, as the produce of these mines will provide for centuries a population of ten times the present number. Close to Bogotá are also situated the celebrated emerald mines of Muzo, which for many years have supplied the great demand for this precious stone in Europe. These mines belong to the government, who have rented them to a company composed of natives and foreigners.

City. The city of Santa Fé de Bogotá was founded in 1538, by Gonzalez Ximenes de Quesada. It stands at the base of two mountains, which are known by the names of La Guadalupe and Monteserrato. At first it consisted of only twelve houses, in honour of the twelve apostles, and contained but sixty inhabitants; but, from its favourable situation, it increased rapidly, and became a place of considerable extent; two years afterwards was raised to the rank of a city; and eventually became the seat of government for the kingdom of New Granada. Its population in 1800 consisted of 21,464, exclusive of strangers and temporary residents; and in that year the number of births exceeded that of

Bogotá. deaths by 247. Its population was estimated at 30,000 in 1821, when, on the union of New Granada and Venezuela, to form the republic of Columbia, it became the capital and the seat of government.

Since the dissolution of Columbia, and its division into three independent republics, Bogotá has continued to be the capital of one of them, namely of New Granada. Its population is estimated at present at 60,000.

The rapid increase of the population has greatly enhanced the value of houses and other property in the city and its vicinity. Nature indeed seems to have pointed out the plain of Bogotá as the most eligible situation which can well be imagined for the formation of a great and opulent city, the seat of government of a powerful nation. It enjoys a genial and salubrious climate, in the midst of a fertile and abundant district; and it forms the centre from which diverge to the north and to the east the two most extensive lines of internal navigation to be found in Columbia.

The communication with the coast is easily effected by means of a carraigeway from Bogotá to El Roble, a distance of 9 leagues, and one for mules from El Roble to Honda, 13 leagues; and between Honda and the coast by the steamers of the Santa Marta, Carthagena and Barranquilla Companies, and lately by those of the Magdalena Steam Company, established in London.

These various steamers scarcely suffice for the increasing traffic, both export and import, of this improving country. The steamers ascend the river in eight or ten days, loaded with foreign merchandize for the consumption of the provinces of the interior, and descend loaded with the tobacco of Ambalema, Penalisa, Geron, Socerro, and the different districts in which this article is produced in excellent quality in New Granada; as also with the bark of Fusagazuga, Pitayo, and other districts, where it is as good as that of Calisaya.

On approaching Bogotá from the Magdalena, the city is seen at a considerable distance, the cathedral and the convents of Guadulupe and Monteserrato being the most conspicuous objects in view. These stand on the summits of two mountains about 2500 feet above the city, which is built at their base. The ascent is steep and difficult; but the labour of the traveller is amply repaid by the magnificent view which he obtains of the city, its convents and gardens, and the whole extent of the plain, with its villages, its hamlets, and cultivated fields. The city itself is somewhat in the form of an amphitheatre, and occupies a larger space than might seem requisite for the number of its inhabitants. The convents, with their extensive gardens, comprise a considerable portion of it; and the houses, on account of the earthquakes, are generally of but one story. The cathedral, built in 1814, possesses very little external beauty; but its interior is fitted up with considerable taste and elegance; its ornaments are rich and valuable; and the statue of the Virgin, who is the patron saint, is covered with a profusion of diamonds and other precious stones. The convents, formerly numerous (about 33), and many of them richly endowed, have of late years fallen into decay, and been devoted chiefly to the service of government, their revenues being mostly applied to educational purposes. There are still, however, about nine convents and three nunneries occupied by religious persons, of which the most wealthy and prosperous are those of Santo Domingo and San Juan de Dios, to which latter there is attached a hospital for the reception of the sick and wounded, affording accommodation to several hundred inmates, who are carefully attended by the friars, and plentifully supplied with everything requisite; besides which, food is here daily distributed to the poor. The convent of San Francisco is of great extent, and under good management. It contains many valuable paintings, the productions of Vasquez, a native artist of considerable merit; one of which, in particular, a Madonna with an infant Jesus, has been mentioned in terms of high commendation. Bogotá.

The university of Bogotá was founded in 1610, since which time two colleges have been endowed with large revenues for the purposes of education. The colleges are now three in number, and in them are educated nearly all the youth of these countries. Formerly the course of study was confined to Latin, mathematics, natural and moral philosophy, and theology; and even then the university produced some men of great eminence for their attainments in the natural sciences; among whom Mutis, Caldas, and Zea hold a distinguished place. Education.

In accordance with the new constitution signed on the 21st May 1853, and which has merited the applause of the liberal portion of the English and United States press, religion and education are completely free, and no forced contributions can be levied at any time or place to support any kind of worship. Foreigners and natives can practise their religion with every liberty, and keep their schools for the education of their children in the manner they may think best.

A military school is supported out of the public funds, which has produced some good engineers; and in some private colleges literature is taught along with the physical sciences, mathematics, and moral philosophy. The scientific and professional degrees have been abolished, and the personal accomplishments of each person alone determine his standing in society.

The mint is a large and handsome building, with coining machinery of great strength and solidity. All the departments are regulated with much precision and minuteness. This is the only mint in the republic of New Granada, with the exception of that of Popayan. We are informed by Humboldt, that from 1789 to 1795, 8,161,862 dollars were coined at Santa Fé de Bogotá, and, from 1788 to 1794, 6,502,542 dollars in Popayan. During the four years 1801–4 inclusive, the amount coined at Bogotá was 5,214,199 dollars, at Popayan, 3,554,878. After this period the coinage seems to have increased in amount, since in Santa Fé de Bogotá alone no less than 3,499,489, dollars were issued in 1806 and 1807. At present the coinage in Bogotá and Popayan is not considerable, because the precious metals are exported in bars or in dust since the duties on their exportation were abolished. The French decimal system in the monies has been adopted since 1847, and in all transactions French silver and other coins of a similar standard are used indiscriminately with the national coinage. These monies are received in exchange for tobacco, coffee, cocoa, gold, and other produce of the country. The gold coinage consists of ten, five, and two-dollar pieces, the ten-dollar piece weighs 16 grains, 409 milligrains, and contains 900 parts of pure gold, and 100 alloy. The doubloons of 16 dollars have been abolished. In public business transactions the French decimal system is universally adopted. Mint.

The square round the cathedral is beautified with a statue of Bolivar in bronze by Teneroni, and a large building constructed on the spot formerly occupied by the palace of the viceroys, and the town hall. In this building are held the sittings of the legislative assembly; also the offices of the ministry of finance, home department, municipality, and the local authorities, are in this building. There also are held the sittings of the provincial government, which, in a country enjoying perfect municipal institutions, is a very considerable body, as it issues laws on all subjects concerning the provinces without the government being able to interfere under any circumstances. The palace of the president is an old Jesuit college repaired and fitted up. The private houses are generally good, and the great influx of foreigners has improved the style of building. The streets, as in almost all cities built by the Spaniards in South America, are formed at right angles to each other; and all those extending from east to west have a small stream of water flowing along them, a convenience which might tend greatly to increase the comfort and cleanliness of the inhabitants, under an improved system of police. Only a few of the principal streets are provided with side pavements. There are four public squares or plazas provided with fountains, and five handsome bridges over two small rivulets which traverse the city.

A public market is held every Friday in the great square, where abundant supplies of all kinds of provisions are exposed for sale, and where may be seen an assemblage of all the varied

Bogotá.

classes which inhabit this country—the Creole, the Mulatto, the Mestizo, the Indian, and the Negro. The supplies of beef, mutton, pork, poultry, and game, are abundant, and moderate in price. Vegetables and fruit are also plentiful, and in the utmost variety; the vegetable productions of the tropical, the temperate, and even cold regions, being all easily attainable, in consequence of the diversified elevation of the surrounding country. One part of the market-place is appropriated to the sale of articles of native manufacture, which consist principally of coarse cotton and woollen fabrics. In the vicinity of the river Funza or Bogotá, which is here an inconsiderable stream, and runs close to the city, is situated the alameda or public promenade, which is inclosed on each side by gardens, and shaded by rows of stately poplars. This forms the favourite resort of the inhabitants during the delightful evenings of summer; and the surrounding gardens afford a place of resort to such parties as desire to solace themselves with the silver tones of their favourite guitar.

Inhabitants.

The society of Bogotá is very agreeable, the inhabitants being mild, polite, and cheerful. They are naturally fond of gaiety and amusements, as is evinced by the frequency of their *tertulias* or evening parties, their balls and concerts. The ladies are remarkably lively and pleasing in their manners: they are generally low in stature, but delicately formed, their feet and ankles being particularly small and handsome, which they set off to great advantage by the neatness of their shoes and silk stockings. The morning dress, in which they usually attend their devotions, consists of the *saya* and *mantilla*. The *saya* or skirt of black kersymere or silk, variously ornamented, fits closely to the body, and is well calculated to show off a fine figure: the *mantilla* covers the neck and shoulders, and sometimes the head, and is kept close to the body by the folded arms. The evening promenade dresses of the ladies are much more showy and diversified, both in form and texture, than those which are worn in the early part of the day, partaking a good deal of the fashions of Europe, which daily become more prevalent; and at their balls and *tertulias* they frequently display the additional ornaments of a profusion of rich and valuable jewels. They dance with much grace and elegance; and among the favourite dances of the country may be noticed the Spanish *contra-danza*, which, by its slow and graceful movements, is peculiarly well calculated to exhibit to advantage the fine figures which they possess in common with most other women of Spanish origin. The females of the inferior classes usually go without shoes or stockings, a practice which often forms a striking contrast with the rest of their attire, which in many cases is both showy and expensive.

Moral condition of the people.

The moral condition of the inhabitants of Bogotá has been variously estimated, and perhaps in most instances incorrectly. The political state of the country before the revolution was such as to afford little scope for the display of striking character. But the eventful scenes of the revolution have given rise to a development of character which shows that they possess in a high degree those qualities which are calculated, with the aid of an improved system of education, to raise them in the scale of civilized communities. Previous to the revolution, the men, besides their ordinary occupations or religious observances, had scarcely any other means of employing their leisure time than by devoting themselves to gambling, cock-fighting, and bull-baiting. The women, brought up in the most profound ignorance and superstition, devoted much of their time to religious matters, and in attendance on the numerous festivals and processions of the church. The want of a good and efficient education, the demoralizing influence of some of the religious practices there prevalent, and the comparatively little estimation in which virtuous conduct in females has hitherto been held, have tended materially to lower the tone of morals in the country. But a new epoch has at length dawned upon them; efficient means have been adopted to promote education and intelligence among all classes; and a purer system of ethics seems to be gradually introducing itself into the country, as has been shown, among other things, by the establishment of a Bible Society in Bogotá, under the able auspices of some of the most influential men of the country, and even aided by the Catholic clergy themselves. Humboldt et Bonpland*; Hall's *Present State of Colombia*; Mollien's *Travels in Colombia*, translated from the French; *Present State of Colombia*; Hamilton's *Travels in Colombia; Campaigns and Cruises in Venezuela, New Grenada, and the Pacific.*) (J. G.) (A. B.)

Bohaddin.

BOHADDIN, or, more properly, Boh-a-Eddyn, an eminent Arabian writer and statesman, better known in the East under the appellation of Ibn-Sjeddad. He was born at Mossul A.D. 1145 (A.H. 539), and early became eminent in the study of the Koran, as well as in jurisprudence. At the age of twenty-seven he obtained the place of lecturer at Baghdad, and, soon after, a professor's chair at Mossul. In 1187 he made the pilgrimage to Mecca, and then proceeded to visit Jerusalem and Hebron. In passing through Damascus he was sent for by Saladin, who was then employed in the siege of Kancab. Bohaddin observed, as he himself mentions (*Vita Saladini*, ch. v.), that the whole soul of the monarch was engrossed by the war which he was then waging against the enemies of the faith; and that the only mode of acquiring his favour was by urging him to its vigorous prosecution. With this view he composed a treatise on the *Laws and Discipline of Sacred War*; and this work, on his return, he presented to Saladin, who received it with peculiar favour. Bohaddin, from this time, remained constantly attached to the person of the sultan, and was employed in various important embassies and departments of civil government. That prince seems also to have sought, by the friendship of so eminent a doctor, to exalt his reputation for sanctity. Often, while riding through the ranks, Bohaddin rode by his side, and read to him passages out of the Koran. Bohaddin was now appointed judge of the army, and judge of Jerusalem. In this latter capacity an incident occurred which proves the impartial justice exercised by the sultan. A merchant presented himself at the tribunal of Bohaddin, and complained that he had been unjustly deprived of a large sum of money. On being asked to name the author of the injury, he replied "the sultan himself." Saladin, on learning the circumstances, denied the truth of the charge; but said that the man should have justice. Accordingly he was introduced into his presence; and the sultan, descending from his throne, pleaded his own cause before Bohaddin. The latter decided in favour of Saladin, and even hinted that the plaintiff merited chastisement. The sultan, however, dismissed the person not only unpunished, but with handsome presents.

Bohaddin continued in favour with Saladin during the whole of that monarch's life; and after his death, he was active in securing the throne to his son Melik-al-Dhaker. That prince created him kadi of Aleppo, which gave Bohaddin an opportunity of founding in that city a college, of which he himself was the principal professor. Under his auspices, the sciences, which had greatly declined in Aleppo, soon rose to more than their former lustre. When Melik-al-Dhaker died, his son Melik-al-Aziz was a minor, and Bohaddin obtained the principal sway in the regency. This gave him an opportunity of introducing learned men at court, and loading them with honours. As the prince, however, approached to manhood, Bohaddin, though he still retained his offices, found it expedient to retire from court. Even after he was unable to go to college, he continued to give lectures in his own house; and he persevered in these learned labours till the age of ninety, when he died A.D. 1235 (A.H. 633).

Bohaddin wrote on jurisprudence and Moslem divinity; but his principal work is his *Life of Saladin*; which, with several other pieces connected with the same subject, was published by Schultens, at Leyden, in 1732, accompanied by a Latin translation, with notes and a geographical index. This work affords a favourable specimen of the historical compositions of the Arabs. It is written with some spirit, and yet is free from that inflation which so frequently disfigures oriental composition. Whatever relates to Saladin, breathes the highest tone of panegyric; yet the enthusiasm with which everything concerning him is narrated, and the

Bohea || Bohemian Brethren.

anecdotes which the author, from his personal knowledge, is able to communicate respecting that extraordinary character, give his work a great degree of interest. (H. M.)

BOHEA, the name given in commerce to black teas, comprehending Souchong, Campo, Pekoe, Congo, and common Bohea. See TEA.

BOHEMIA. See AUSTRIA.

BOHEMIAN or MORAVIAN BRETHREN. Christianity was originally introduced into the Slavonian provinces lying between Germany and Turkey, not from Rome but from Constantinople, in the ninth century, under their native princes. In the tenth century Bohemia and Moravia were conquered by Otho I. of Austria, when, with imperial despotism, ecclesiastical domination was attempted to be enforced upon the inhabitants. Arms could subdue the land, and the law of the strongest compel the submission of an enslaved people, but neither violence nor priestcraft could subjugate or ensnare the conscience of the true converts to the gospel. These ever maintained the doctrines and the ordinances of their primitive church; and never relinquished the Scriptures in their own language, the holy communion in both kinds, and the right of their clergy to marriage. Though popery gradually gained ascendency among the multitude, with whom religion was a profession, those with whom it was a reality clave to that which they had received from their fathers, who had received it from the earliest age of the church on earth, whose teachers had been the apostles and evangelists, and Jesus Christ himself their "*One Master*."

In the thirteenth century, King Richard II. of England married a Bohemian princess, who had became acquainted with the disciples of our Wickliffe, "the morning star of the Reformation" both in England and Germany, as he has been worthily styled. The writings of this great light shining in a dark world, by the queen's correspondence with her native country, were transmitted thither, translated, and eagerly approved by the faithful in Bohemia and Moravia. Among these, in the fifteenth century, John Huss, for maintaining the Scriptural doctrines which they promulgated, was burned by the popish council of Constance. After his death a schism arose among his followers,—many taking the sword to fight for their faith, and a few choosing rather to perish by the sword than defend that faith with carnal weapons.

Out of the small peace party sprang "the United Brethren," as a distinct denomination, under episcopal government, having received the rite of ordination from the Waldenses. This little flock during the two next centuries, like their forerunners in all ages, were persecuted with unrelenting malignity by the bigoted priesthood; while, at the instigation of the latter, on sundry occasions war was waged against them by the Austrian tyrants under whose yoke they had been born. At length, about 1660, the remnant were either scattered through the adjacent provinces of Germany and Poland, or were compelled to hide themselves among the fastnesses of their native forests and precipitous mountains. Their last bishop, Amos Comenius, took refuge in England; and thinking that his people were about to cease from the earth, he commended their cause while they did yet exist to their pious brethren of the church of England, for the preservation of their memory and their name.

In the year 1650, was published in London, by certain refugees from Bohemia, for the information of Christians in England, *The History of the Bohemian Persecution, from the beginning of their conversion to Christianity, in the year* 894, *to the year* 1632, *Ferdinand the Second of Austria reigning, in which the unheard of secrets of policy, councils, arts, and dreadful judgments, are exhibited.* Printed by B. A. for John Walker, at the Star in Pope's Head Alley, M.D.C.L." This volume, which has now become very rare, was avowedly compiled as supplementary to Foxe's *Book of Martyrs*, to show in this country how much had been suffered on the Continent in "the dark places of the earth," which, as well as here, were "full of the habitations of cruelty and wickedness," during the death-pangs of expiring error, and the birth-pains of regenerating truth in the nominally Christian world. Bohemian Brethren.

The following specimen of the style and contents of this remarkable chronicle may suffice:—"New edicts were published in the name of the king and the consistory, that these pernicious men should nowhere be suffered either in Bohemia or Moravia. Hence it came to pass, that many, especially the chiefest among them, being dispersed among the woods and mountains, did dwell in caves where they were scarce secure enough; wherefore they dressed not their meat, nor made any fire but in the night only, for fear the smoke ascending should betray them; and in the extremity of the cold in winter nights, sitting near the fire, they gave themselves to reading of the Bible and holy discourses. When, in the depth of the snow they went forth to provide themselves necessaries, they went close together lest they should be discovered by their footsteps, and the hindermost did draw behind him a great bough of beech, to cover the print which their feet had made in the snow, that nothing might be seen but the impression of some country lad drawing a bush behind him."

About this period some of the persecuted refugees obtained protection and privileges from the English government; and the Church of Austin Friars, in the centre of London, was granted to one of the ministers of the Brethren, John de Lazco, with the distinct superintendence over the members of Protestant congregations from Bohemia, Moravia, Poland, and Hungary. Again, in the reigns of Charles II. and George I., the case of these sufferers was recommended by briefs read, and monies to be collected for their aid, in the churches throughout the kingdom; with the express sanction of two successive archbishops of Canterbury, who, with the Lord Chancellor, the Archbishop of York, and Bishops of London, Carlisle, Sarum, Norwich, and Bristol, were appointed trustees for the advancement of the charity. On both these occasions, the credentials of these foreigners, after rigid scrutiny, were avouched as follows:—"The Bohemian Church has been free from her infancy, and for almost 700 years, from the encroachment of the Roman See; crushed at length by its prevailing powers, she brought forth a progeny, which, growing up in Bohemia, obtained the name of UNITAS FRATRUM. This fraternity, the heir of the truly ancient faith, spread its boughs as far as Poland, renounced the errors of Popery, and preserved the succession of episcopal orders."

Amidst all their tribulations the Brethren *laboured* incessantly as well as *suffered* patiently, and in them were literally exemplified the declarations of the apostle concerning the ancient worthies:—they "had trial of cruel mockings and scourgings, yea, moreover, of bonds and imprisonments; they were stoned, they were tempted, were slain by the sword, being destitute, afflicted, tormented,—of whom the world was not worthy." From their origin till their apparent extinction towards the close of the seventeenth century, they were merely *a church of martyrs and confessors.* During the lucid intervals from persecution, they were the first people who employed the newly invented art of printing for the publication of *the Bible* in a living tongue, and three editions of the Bohemian Scriptures were issued by them before the Reformation. When Luther, Melancthon, Calvin, and Bucer, at length arose to testify the truth more successfully than they had been able to do, to each of these illustrious men the Brethren submitted their doctrinal tenets, their church discipline, and the records of their affairs; and from each, in return, they received assurances of cordial approbation and the kindest encouragement.

Sixty years after the suspended animation which followed the flight of Comenius from Moravia, the church of the United Brethren was raised from the dead. "*A remnant*

Bohol

was saved." A few individuals and their families gradually, and by stealth as it were, emigrated from their own country and found refuge on the estates of Count Zinzendorf, in Lusatia, where they built a humble village, and named it *Herrnhut*. This is still the principal settlement of the society, which has at this day affiliated stations, *Home* and *Missionary*, to the ends of the earth.

The United Brethren first appeared in England as a body before the middle of the last century, where (although the most malignant slanders were circulated against them), with the simplicity of conscious innocence, they laid their case before parliament, their doctrines, discipline, history, and character. These were scrupulously investigated by committees of both houses; and two bills, exempting them from taking oaths, and bearing arms in certain cases, were carried with the unanimous consent of all the bishops; indeed all opposition was abandoned after the final test of their claims; and they were thus fully acknowledged by the British legislature to be "*An Ancient Protestant Episcopal Church, which had been countenanced and relieved by the kings of England, his Majesty's predecessors.*" (See acts 20th Geo. II. cap. 44, and 22d Geo. II. cap. 30, passed in 1747 and 1748; also a Congratulatory Letter from Archbishop Potter to Count Nicholas Lewis Zinzendorf, one of their bishops, on his consecration; including this testimony: "I should be entirely unworthy of that high station in which Divine Providence has placed me, were I not to show myself very ready to use every exertion for the assistance of the universal church of God; but to love even preferably your Church, united with us in the bond of love; having hitherto, as we have been informed, invariably maintained both the pure and primitive faith and discipline of the first Church; being neither intimidated by dangers, nor seduced by the manifold temptations of Satan."

The revived Church of the United Brethren, on the estates of Count Zinzendorf, in Lusatia, including their expatriated countrymen and pious persons from other quarters, gradually multiplied through Germany, Denmark, Russia, Holland, and North America. But, when their number at Herrnhut scarcely amounted to 600 persons, when they had only rested from suffering, and were beginning to build their first church, and lay out their first burying-ground,—the missionary spirit was sent down upon them with such constraining influence, that in the short period of eight years, they had messengers of peace in Greenland, Lapland, North and South America.

At present (1853) the church of the Brethren numbers about 20,000 Europeans, and has 293 missionaries and 70 stations in Greenland, Labrador, and South America, the West Indies, South Africa, and Australia. The number of converts and heathen receiving instruction is as follows:—

British Subjects...	Negroes	30,741	
	Indians	205	
	Hottentots	6,191	
	Esquimaux	1,321	
			38,458
Danish	Negroes	10,252	
	Greenlanders	2,102	
			12,354
Dutch	Negroes		18,972
United States	Indians		286
		Total,	70,070

The annual expenses of carrying on this great work little exceed L.12,000, and of this sum about one-half is contributed by Christian friends of various other denominations,—a glorious example of that "*Charity which never faileth;*" and showing that it may still be said, as of old, "*See how these Christians love one another!*" (J. M—Y.)

BOHOL, or Bool, one of the Philippine Islands between Mindanao and Leyte, discovered by Magellan in 1521. It is in Long. 124. 15. E. Lat. 10. N., and is about 40 miles in length, and 32 in breadth. It produces some gold.

Boiardo.

BOIARDO, Count Matteo Maria, of a noble and illustrious house established at Ferrara, but originally from Reggio, was born at Scandiano, one of the seignoral estates of his family, near Reggio di Modena, about the year 1434, according to Tiraboschi, or 1420 according to Mazzuchelli. At an early age he entered the university of Ferrara, where he applied to his studies as regularly as if he had not been a person of quality, nor belonged to the privileged class He acquired the Greek and Latin, and even the oriental languages, and was in due time admitted doctor in philosophy and in law. At the court of Ferrara, where he enjoyed the favour of Duke Borso d'Este and his successor Hercules, he was invested with several honourable employments, and in particular named governor of Reggio, an appointment which he held in the year 1478. Three years afterwards he was elected captain of Modena, and re-appointed governor of the town and citadel of Reggio, where he died in the year 1494, though in what month is uncertain. Almost all of his works, and especially his great poem of the *Orlando Inamorato*, were composed for the amusement of Duke Hercules and his court, though not written within its precincts. His practice, it is said, was to retire to Scandiano or some other of his estates, and there to devote himself to composition; and Castelvetro, Vallisnieri, Mazzuchelli, and Tiraboschi, all unite in stating that he took care to insert in the descriptions of his poem those of the agreeable environs of his chateau, and that the greater part of the names of his heroes, as Mandricar, Gradasse, Sacripant, Agramant, and others, were merely the names of some of his peasants, which, from their uncouthness, appeared to him proper to be given to Saracen warriors. But be this as it may, the *Orlando Inamorato* deserves to be considered as one of the most important poems in Italian literature, since it forms the first example of the romantic epic worthy to serve as a model, and, as such, undoubtedly produced the *Orlando Furioso*. Gravina and Mazzuchelli have said, and succeeding writers have repeated on their authority, that Boiardo proposed to himself as his model the Iliad of Homer; that Paris is besieged like the city of Troy, that Angelica holds the place of Helen, and that, in short, the one poem is a sort of reflex image of the other. In point of fact, however, the subject-matter of the poem is derived from the *Fabulous Chronicle* of Turpin; and with the exception of the names of Charlemagne, Roland, Oliver, and some other principal warriors, who necessarily figure as important characters in the scene, there is not the least resemblance or analogy between the fable of the one and that of the other. This poem, which Boiardo did not live to finish, was printed at Scandiano the year after his death, under the superintendence of his son Count Camile. The title of the book is without date; but a Latin letter from Antonio Caraffa di Reggio, prefixed to the poem, is dated the kalends of June 1495. A second edition, also without date, but which must have been printed before the year 1500, appeared at Venice; and the poem was there twice reprinted during the first twenty years of the sixteenth century. These editions are the more curious and valuable, that they contain nothing but the text of the author, which is comprised in three books, divided into cantos, the third book being incomplete. But Niccolo degli Agostini, a mediocre poet, had the courage to continue the work commenced by Boiardo, adding to it three books, which were printed at Venice in 1526–1531, in 4to; and since this time no edition of the Orlando has been printed without the continuation of Agostini, wretched as it unquestionably is. Nor is this all. Successive rifacciamenti were executed by Domenichi and Berni, who took prodigious liberties, especially with the style, which they chose to consider as feeble, and ill suited to the high qualities of the poem in other respects; and the consequence has been, that the original composition has

Boileau-Despreaux.

been nearly overlaid by these innovations, and that the romantic epic invented by Boiardo is now almost universally read as remodelled by Berni. The other works of Boiardo are, 1. *Il Timone*, a comedy, Scandiano, 1500, 4to; 2. *Sonnetti e Canzoni*, Reggio, 1499, 4to; 3. *Carmen Bucolicon*, Reggio, 1500, 4to; 4. *Cinque Capitoli in terza rima*, Venice, 1523 or 1533; 5. *Apulejo dell' Asino d'oro*, Venice, 1516, 1518; 6. *Asino d'oro de Luciano, tradotto in volgare*, Venice, 1523, 8vo; 7. *Erodoto Alicarnasseo istorico, tradotto di Greco in Lingua Italiana*, Venice, 1533 and 1538, 8vo; 8. *Rerum Italicarum Scriptores*. (*Biographie Universelle;* Tiraboschi, *Storia della Letterat. Ital.* lib. c. 3. sect. 26, 33; Crescembeni, tom. i. and iii.) (J. B—E.)

BOILEAU-DESPREAUX, Nicolas, a celebrated French poet, born at Paris, or at Crosne, November 1. 1636. After he had gone through a course of literature and philosophy, his relations induced him to study the law, and he was admitted advocate at the age of twenty-one. But though he had all the talents necessary for the bar, he could not adapt himself to a science which turns upon continual equivocations, and often obliges those who follow it to clothe falsehood in the garb of truth; and it may be imagined that the dreamy tomes of Accursius and of Alciat afforded no congenial nourishment to the disciple of Horace and Juvenal. He accordingly deserted what his biographers call "l'antre de la chicane," and determined to study theology. He soon found, however, that scholastic divinity had its tricks and quirks as well as law; and imagined, that in order to allure him the more cunningly, chicanery, which he thought to avoid, had only changed her habit. Renouncing, therefore, the Sorbonne, he applied himself entirely to the study of the belles-lettres, and soon occupied one of the most distinguished places on the French Parnassus. The public gave his works the reception they deserved; and Louis XIV. not only had Boileau's works read to him as they were composed, but settled a yearly pension of 2000 livres upon him, and gave him the privilege of printing all his works. He was afterwards chosen a member of the French academy, and also of the academy of inscriptions. This great man, who was as remarkable for his integrity, his innocence, and diffusive benevolence, as for the keenness of his satire, died of a dropsy in the chest on the 13th of March 1711, in the seventy-fifth year of his age. The *Lutrin* of Boileau, still considered by some French critics as one of the best poems to which France has given birth, was first published in 1674. But it is with great reason and justice that Voltaire confesses it inferior to the *Rape of the Lock*. There are two actions recorded of Boileau, which sufficiently prove that the inexorable satirist had a most generous and friendly heart. When Patru, the celebrated advocate who was ruined by his passion for literature, found himself under the painful necessity of selling his extensive library, and had almost agreed to part with it for a moderate sum, Boileau tendered him a higher price, and, after paying the money, added this condition to the purchase, that Patru should retain, during his life, the possession of the books. Another instance of the poet's generosity is of a yet nobler character. When it was rumoured at court that the king intended to retrench the pension of Corneille, Boileau hastened to Madame de Montespan, and represented that his sovereign, equitable as he was, could not, without injustice, grant a pension to an author like himself, just ascending Parnassus, and withdraw it from Corneille, who had so long been seated on the summit; he entreated her, for the honour of the king, to prevail on his Majesty rather to strike off *his* pension than to withdraw that of a man whose title to that which he enjoyed was incomparably greater; and he declared that he could more easily console himself under the loss of that distinction, than under the affliction of seeing a just reward taken away from such a poet as Corneille. This magnanimous application had the success which it deserved; and it appears the more noble, that the rival of Corneille was the intimate friend of Boileau. The long and unreserved intercourse which subsisted between Boileau and Racine was highly beneficial and honourable to both. The dying farewell of the latter is the most expressive eulogy on the private character of Boileau: "*Je regarde comme un bonheur pour moi de mourir avant vous,*" said the tender Racine, in taking a final leave of his faithful and generous friend. As a satirist Boileau is inferior to Horace; but in his Epistles he almost equals his illustrious model; whilst in regularity of plan, felicity of transition, and a firm, sustained elegance of style, his *Art Poetique* will stand a comparison with the celebrated *Epistle to the Pisos*.

Boii || Boissard.

The works of Boileau consist of his *Satires;* his *Epistles;* his *Art of Poetry*, including his Epigrams, and some other pieces of French and Latin poetry; his *Dialogue on Poetry and Music;* a *Dialogue on the Heroes of Romance;* a *Translation of Longinus's Treatise on the Sublime*, with *Critical Reflections* on that author. The best edition of them, perhaps, is that with the notes and commentaries of M. Daunou, printed at Paris in 1809, in 3 vols. 8vo; but the edition of 1747 by Lefevre de Saint-Marc, in 5 vols. 8vo, with cuts, and accompanied with the remarks of Brossette, is the most *recherchée*. His life has been written by Desmaizeaux, Amst. 1712, 12mo.

BOII, a people of ancient Gaul, who made immigrations into Germany and Italy, and appear to have given their name to Bohemia and to Bologna. (*Niebuhr*).

BOILING, the effect produced on liquids by the application of heat sufficient to convert them rapidly into vapour, with the phenomena of ebullition. The boiling point varies greatly in different liquids, and is also affected by the degree of atmospheric pressure, being higher when the pressure is increased, and lower when it is diminished. When the barometer stands at 30 inches, the boiling point of water is 212° Fahr., and it is found to vary 0·88 of a degree for each half inch of barometric variation: consequently, for every variation of one-tenth of an inch in the barometer, the boiling point of water is altered 0·176 of a degree. Hence water will boil sooner at the top of a mountain than at its base; and thus a method is afforded for determining its height. Water boils *in vacuo* at 98° Fahr. Under a uniform barometric pressure of 30 inches, mercury boils at 662°; alcohol at 176°; ether at 96°; and oil of turpentine at 316° Fahr.

Boiling Springs. See Iceland; Physical Geography.

BOIS-LE-DUC, or Hertogenbosch, a city of Holland, capital of the province of North Brabant, 28 miles S.S.E. of Utrecht. It stands at the confluence of the Dommel and the Aa, and is strongly fortified, being defended by a citadel and two forts. The city is handsome and well built, and is intersected by several canals. It contains seven churches, among which is that of St John, founded in the beginning of the fourteenth century, and one of the finest ecclesiastical edifices in Holland. It has also a handsome town-hall, surmounted by a tower containing a fine set of chimes, an orphan asylum, grammar-school (once attended by Erasmus), prison, two hospitals, an arsenal, and barracks for 3000 troops. The trade of Bois-le-Duc is very considerable: it has several distilleries and glass-works, and manufactures of linen, needles, cutlery, &c. It is the seat of a vicar-general, and has tribunals of primary instance and commerce. Pop. 21,000.

BOISSARD, Jean Jacques, a classical antiquary and Latin poet, born at Besançon in 1528. He studied at Louvain; but, disgusted by the severity of his master, he secretly left that seminary, and after traversing a great part of Germany reached Italy, where he remained several years, and was often reduced to great straits. His residence in Italy developed in his mind a taste for antiquities, and he soon formed a collection of the most curious monuments of Rome and its vicinity. He then visited the islands of the Archipelago, with the intention of travelling through Greece, but a severe illness obliged him to return to Rome. Here he resumed his favourite pursuits with great ardour; and

Bojador || Bolingbroke.

having completed his collection, returned to his native country. But not being permitted to profess publicly the Protestant religion, which he had embraced some time before, he withdrew to Metz, where he died, Oct. 30. 1602, aged seventy-four. His works are:—

1. *Poemata, Epigrammatum libri tres, Elegiæ libri tres, Epistolarum libri tres*, Basle, 1574; 2. *Emblemata*, Latin and French, Metz, 1584; 3. *Emblemata*, Latin, Francfort, 1595; 4. *Vitæ et Icones Sultanorum Turcicorum*, &c., Francfort, 1596; 5. *Theatrum Vitæ Humanæ*, Metz, 1596; 6. *Romanæ Urbis Topographiæ et Antiquitatum, quibus succincte et breviter describuntur omnia quæ tum publice quum privatim videntur animadversione digna, partes vi.*, Francfort, 1597, 1598, 1600, and 1602, folio, six tomes in three, with plates, and now very rare; 7. *Icones et Vitæ Virorum Illustrium*, Francfort, 1592 to 1599; 8. *Parnassus Biceps*, Francfort, 1601; 9. *De Divinatione et Magicis præstigiis*, Oppenheim and Hanau, rare and curious; and, 10. *Habitus Variarum Gentium*, Metz, 1581, ornamented with seventy illuminated figures.

BOJADOR, a cape of Western Africa, which projects considerably into the sea, and presents a very rugged and dangerous aspect. The Portuguese were long deterred by it from prosecuting their career of discovery in this direction. It was at length passed by Gellaney; and vessels navigating the Atlantic now stand too far out to sea to be exposed to any danger. Lat. 26. 7. N. Long. 14. 29. W.

BOKHARA. See Bukharia.

BOL, Ferdinand, a Dutch painter, born at Dordrecht about 1610, was one of Rembrandt's most distinguished pupils. His works are chiefly found at Amsterdam, where he died in 1681 or 1686.

BOLABOLA, or Borabora, one of the Society Islands, in the South Pacific Ocean. It is about twenty-four miles in circumference, and is surrounded by a reef of rocks and islets. A very lofty double-peaked mountain rises in the centre. There is a border of low land along the coast, which is very fertile, and covered with cocoa-nut and bread-fruit trees. The island is populous, and the inhabitants are of a more warlike disposition than their neighbours, some of whom they have subdued. Long. 151. 52. W. Lat. 16. 32. N.

BOLBEC, a town of France, capital of a canton of the same name, in the department of Lower Seine, on the Bolbec, and on the railway from Paris to Havre, 18 miles E.N.E. of the latter. It is a handsome and flourishing manufacturing town; the streets are wide and well laid out, and the suburbs contain many neat houses. The principal manufacture is cotton; besides which it has woollen and linen factories, dye-works, and tanneries. Pop. 9000.

BOLE, an opaque, earthy mineral, occurring in solid amorphous masses, of a yellow, red, or brownish colour. It yields to the nail, and cuts easily, has a conchoidal fracture, with a shining streak, and adheres to the tongue. Its specific gravity is between 1·60 and 2·00, and when thrown into water it emits a crackling noise, and falls to pieces. It occurs in wacké and basalt at Striegau in Silesia, at Habichtswald in Hessia, near Sienna in Tuscany, and among the cliffs of the Giant's Causeway, Ireland. Armenian bole is used as a coarse red pigment.

BOLEYN, Anne. See Anne Boleyn.

BOLI, a town of Asiatic Turkey, in Natolia, 85 miles N.W. of Angora. It is the capital of a district, and the residence of a governor, and contains numerous public edifices, though nowise remarkable in their structure. In the vicinity are the ruins of the ancient Hadrianopolis, and many marble fragments with Greek inscriptions. The country around is fertile; and in the neighbourhood is an extensive forest, which supplies Constantinople with a great quantity of wood. Long. 31. 19. E. Lat. 40. 35. N.

BOLINGBROKE (Henry St John) Viscount, was the only son of Sir Henry St John, a baronet of ancient family, and was born on the 1st of October 1678, at the family seat at Battersea. During the early years of his life he was intrusted to the care of his grandmother, a rigid and somewhat fanatical Presbyterian, from whose religious adviser, Daniel Burgess, the future orator received the rudiments of his education. Burgess, like his patroness, was somewhat of a fanatic, and was more desirous to indoctrinate his pupil in the principles of the Presbyterians, than in the languages of ancient Greece and Rome. To the injudicious rigour of his discipline may be traced that prejudice against religion which taints the most elaborate of St John's compositions. The time came at length when the pupil was delivered from the jurisdiction of both his grandmother and tutor, and to his great joy he was sent to Eton. Nothing is known of his history at that college, save that he made the acquaintance of Robert Walpole. The future statesmen were even at this early period rivals, and the bitter malignity with which Bolingbroke in after life assailed the great minister is said to have arisen out of the quarrels of their school days. From Eton he went to Christ Church, Oxford, where he astonished his tutors by the extraordinary quickness of his apprehension and the strength of his memory; while he dazzled his fellow-students by the splendour of his appearance and the wit and brilliancy of his conversation. From Oxford he removed to London, where he persisted for a time in his career of debauchery with such success that he came to be regarded by the most licentious men of the age as an irreclaimable libertine, and by such of them as remembered the days of Charles II., was likened to the infamous Rochester. Even Swift does not attempt to defend this period of his life, but expresses his belief that he lived long enough to regret and repent of it. The intervals of his excesses he employed in writing poetry; and when Dryden published his translation of Virgil, he recommended it in a copy of verses prefixed to the first edition of that work. His next public appearance was made in 1700, when he gave to the world an ode entitled *Almahide*, which was so bad that it did not elicit even a hostile criticism. A few other pieces which he wrote at this time have not been preserved. About this time he went abroad and travelled on the Continent for two years, spending the most of his time in France and Italy. The knowledge of French which he was in this way enabled to acquire was of signal service to him in after life. In 1700 he married the daughter of Sir Henry Winchescomb, with whom he received a handsome fortune; but so incompatible was his temper with that of his bride, that in a short time they were formally separated. In the following year he began his political career, by representing in parliament the borough of Wootten Basset. The family to which he belonged had been known for several generations as firm supporters of the Whig faction; but the young member consulted at once his interests and his inclination by siding with the Tory party, then promising to become dominant in England. Harley was at this time speaker in the House of Commons; and his dexterity was such as to make him respected alike by his own friends and the Opposition. To Harley St John attached himself, and so effectually did he assist him in difficult conjunctures with the whole weight of his personal and family interest, and the fire of his splendid eloquence, that when Harley was made secretary of state in 1704, St John, as a reward for services, was appointed secretary at war. In 1707, after a long series of court intrigues, the queen was induced to dismiss her secretary, and St John, hitherto consistent, immediately gave in his resignation. He retired not only from office but from parliament, and for the next two years devoted himself wholly to study. These two years he repeatedly mentions as the happiest of his life. It was not long, however, before he was called upon to quit his retirement and direct his attention once more to public affairs. While St John was thinking and writing in the solitude of the country, Harley, after the manner of these days, had been busily intriguing at court. The result of his machinations was that the Whigs were in their turn ousted, and the Tory administration once more reinstated. Harley

Bolingbroke.

Boling-broke.

became chancellor of the exchequer. St John took office as secretary of state in 1710, and was soon acknowledged ministerial leader in the House of Commons. Circumstances, however, soon transpired which made it apparent that these two men, hitherto so true to each other, could no longer act in concert. For when in 1712, Harley, now Lord Oxford, refused to secure for his late coadjutor a rank in the peerage equal to his own, St John's indignation knew no bounds. He resolved, however, for the ultimate advancement of his interests, to maintain at least the appearance of friendship with the successful minister. Mr St John was therefore in the meantime obliged to content himself with the title of Viscount Bolingbroke. His ambition, however, was far from being satisfied even with so honourable a distinction, and he now determined to turn against his ancient friend and ally the very weapons by means of which that friend had cleared his way to power. He was no less skilful in the conduct of a court intrigue than Oxford himself had been, and at length, through the influence of Mrs Masham the queen's favourite, whose good graces he had cultivated assiduously for two years, he obtained the dismissal of the lord treasurer in 1714. Two years before this consummation he had been sent as ambassador to the French court, and his conduct while there was such as to justify his enemies in the clamorous outcry which they raised against him. It was suspected, and not without reason, that Bolingbroke's object in visiting Paris was not so much to negotiate the details of a general peace, as to make arrangements for the restoration of the exiled royal family. It was reported in England that he had had at least one interview with the Pretender; it is now clearly ascertained that he had two. His conduct, which had long been most suspicious, was now openly canvassed with the utmost freedom. His useless and wanton treachery in the matter of the peace of Utrecht was remembered against him; the readiness with which he had deserted his party and his old patron Oxford, when the opposition was once more in the ascendant, was not forgotten; and even the follies and vices of his early manhood were cast up to him. These circumstances all marked him out as a man eminently unscrupulous, and reckless of the national honour, when it interfered with the prospects of his personal advancement. The airy fabric of his ambition, however, was overthrown by a circumstance of which he had never contemplated the possibility, and which he could not prevent. The queen died; George I. was quietly proclaimed; and the ambitious secretary was deprived of the seals. Harley laboured under the same suspicions with himself: each was suspected of favouring the cause of the Pretender, though from different motives. It was now resolved that both of them should be impeached. Bolingbroke received notice of his impending danger and fled to France, where he was warmly welcomed by the Pretender and his party, and pressed to accept the office of secretary. This office he held for a very short time. He failed as completely to secure the confidence of his new master as of his old partizans in England, and in 1716 was dismissed. In 1718 his wife died. Two years after he married the Marquise de Villette, the niece of Madame Maintenon, a widow of large fortune. He resided for some years upon his wife's property, devoting his time entirely to literary pursuits, and the entertainment of literary men. Amongst others who visited him in his retreat was the young Voltaire, who submitted to him the manuscript of the *Henriade*, which he had just completed. It was now that he composed his *Reflections upon Exile*. In 1723 he was informed that he was at liberty to return to England. He accordingly returned to his native country, where he remained, however, for a very short time. He soon returned to France, and removed thence to Aix-la-Chapelle. In 1724 he once more revisited England, and had the satisfaction of learning in the following year that the bill of attainder against him was reversed, and that he was now at liberty to resume his title and his fortune. Provision, however, had been expressly made that he should never again cross the threshold of the House of Lords. This qualified pardon Bolingbroke attributed to the influence and intrigues of Sir Robert Walpole. His old hostility against that minister revived, and for ten years he opposed his policy with all the bitterness and malignity of which he was capable. His invectives he published in the form of letters, under the title of *The Occasional Writer*. The success which attended these letters, and another series that appeared in a paper called the *Craftsman*, was so great as to place their author above all the political pamphleteers of the day, Swift alone excepted. Some of these contributions were afterwards republished, and have descended to us as the *Letters on the History of England*. So great was the impression they produced that the government prosecuted the publisher, and menaced the author in a manner that elicited from him one of the most brilliant and witty of all his compositions. Finding at length that, on the accession of George II. his hopes of political preferment were blighted for ever, he resolved to retire to France, and devote the remainder of his days to the study of history and philosophy. He set out for the Continent with his wife early in 1735, and did not again visit England till summoned by the death of his father in 1742. Bad health once more drove him to France, and shortly after to the baths of Aix-la-Chapelle. In 1744 he bade a last farewell to the Continent. He returned to England only to find that all the friends of his early years had passed away. Gay, Prior, Atterbury, and Windham were gone; Swift had recently died; and Pope did not survive him long. By his will the great poet appointed Bolingbroke his literary executor, and made over to him all his manuscripts "to preserve or to destroy." None of these documents were allowed to see the light, and the statesman ever persecuted the memory of the poet with a rancour that has not yet been satisfactorily explained. From this time till his death he devoted all his time and energies to correcting and arranging his works for posthumous publication. Lady Bolingbroke, whose health had been for a long time declining, died in 1750, and on the 15th December 1751, her husband closed his stormy career. He was buried beside his wife in the family vaults at Battersea, where a long epitaph, written by himself, records his history, his virtues, and his misfortunes.

Boling-broke.

Bolingbroke's fame with posterity will rest chiefly on his oratory. No specimen of his oratorical powers has descended to our times, save a small fragment, of which the finest passage is avowedly borrowed from Demosthenes. When we recollect, however, the great natural advantages he possessed, the splendour of his personal appearance, his clear and powerful voice, and his action unsurpassed for ease and grace; when we remember, moreover, his great natural endowments, which he had taken care to improve by long and severe study, his great acquaintance with history, his brilliant wit, and the copious felicity of his diction, we cannot but believe that he takes rank as on the whole the greatest of British orators. Such was the opinion of Pitt, who, on one occasion discoursing on the lost treasures of the past, and hearing his friends lament, one the lost books of Livy, another those of Tacitus, declared that for his part he regretted most of all the speeches of Bolingbroke. Such, too, is the opinion of Lord Brougham, the greatest orator of our own day. As a writer his influence has long since passed away—a circumstance which made Burke ask "Who now reads Bolingbroke?" As a speculator he merits little gratitude from posterity. When Dr Johnson was asked his opinion of Bolingbroke's ethical works, he replied "Bolingbroke, sir, was a scoundrel and a coward; he loaded a blunderbuss against Christianity, which he had not the courage to fire during his lifetime; but left half-a-crown to a hungry Scotsman to draw the trigger after he was dead." The "hungry Scotsman" here alluded to was David Mallet, to

Bolivar. whom Bolingbroke intrusted the publication of his works. They appeared, in a handsome edition in 5 vols. 4to, Lond., 1754. They were afterwards reprinted, with a life by Goldsmith, in 8 vols. 8vo, 1809.

BOLIVAR, SIMON, the hero of South American independence, was born in the city of Caraccas, on the 24th July 1783. His father was Don Juan Vicente Bolivar y Ponte, and his mother Dona Maria Concepcion Palacios y Sojo, both descended of noble families in Venezuela. After acquiring the elements of a liberal education at home, Bolivar was sent to Europe to prosecute his studies, and with this view repaired to Madrid, where he appears to have resided for several years. Having completed his education, he spent some time in travelling, chiefly in the south of Europe, and visited the French capital, where he was an eye witness of some of the last scenes of the revolution. Returning to Madrid, he married the daughter of Don N. Toro, uncle of the marquis of Toro in Caraccas, and embarked with her for America, intending, it is said, to dedicate himself to domestic life and the improvement of his large estate. But this plan was frustrated by the premature death of his lady, who fell a victim to yellow fever; and Bolivar again visited Europe, in order, by change of scene, to alleviate the sorrow occasioned by this bereavement.

On his return home he passed through the United States, where, for the first time, he had an opportunity of observing the working of free institutions; and soon after his arrival in Venezuela he appears to have embarked in the schemes of the patriots, and pledged himself to the cause of independence. Being one of the promoters of the movement at Caraccas in April 1810, he received a colonel's commission from the supreme junta then established, and was associated with Don Luis Lopez Mendez in a mission for communicating intelligence of the change of government to Great Britain. He took part in the first military operations of the Venezuelan patriots, after the declaration of independence on the 5th of July 1811; and in 1812, when the war commenced in earnest, by the advance of Monteverde with the Spanish troops, he was intrusted with the command of the important post of Puerto Cabello. But the castle of San Felipe, which commanded the town, having been treacherously surrendered to the Spaniards, Bolivar was compelled to evacuate the place; and Miranda having soon afterwards made his peace with the government, Venezuela submitted to Monteverde, while those who had been most deeply committed in the revolution consulted their safety by quitting the country. On this occasion Bolivar succeeded in obtaining a passport under a fictitious name, and made his escape to Curaçoa.

But as important events were passing on the continent, he repaired to Carthagena in September 1812, and, with other refugees from Caraccas, joined the patriots of New Grenada, who gave him a command in the small town of Baranca, under the orders of Labatut, the republican governor of Santa Martha. Not content, however, with the obscure part of a subaltern at Baranca, Bolivar undertook an expedition against Teneriffe, a town higher up on the Magdalena; and having made himself master of the place, proceeded to Mompox, driving the Spaniards before him from all their posts on the Upper Magdalena, and finally entering Ocaña in triumph amidst the acclamations of the inhabitants. He then marched upon Cucuta; defeated a Spanish division commanded by Correa; and, emboldened by success, conceived the design of invading Venezuela, and expelling Monteverde. The congress of New Grenada approved of the project, and gave him a commission as brigadier; but from the jealousy of some, the lukewarmness of others, and the procrastination of all, many disheartening obstacles were thrown in his way. By zeal and Bolivar. perseverance, however, he at length surmounted every difficulty, and commenced his march for Venezuela with little more than 500 men. At the head of this handful of troops he boldly entered the province of Merida; made himself master of the provincial capital, where, on learning the news of his approach, the inhabitants rose upon the Spaniards; re-established the republican authorities there; then pushed his vanguard under Jirardot upon Trujillo, where a corps of royalists under Cañas was defeated; and finally expelled the Spaniards from the provinces of Merida and Trujillo. While he was thus carrying every thing before him, Bolivar obtained intelligence of the cruelty and oppression exercised by Monteverde and his subordinate officers in Venezuela; and, exasperated at their barbarity, as well as desirous to give a check to their excesses, he issued the famous decree of *guerra a muerte*, condemning to death all Spanish prisoners who might fall into his hands.

Bolivar's army increasing daily, he now formed it into two divisions, one of which he committed to the charge of Rivas, and advanced rapidly on Caraccas through the provinces of Trujillo and Varinas. After a variety of encounters, which generally terminated in favour of the patriots, a decisive battle was fought at Lastoguanes, where the flower of Monteverde's troops sustained a total defeat, and the road to Caraccas was in consequence left uncovered. Monteverde threw himself into Puerto Cabello, and Bolivar lost no time in marching on the capital, which being evacuated by the Spaniards, he entered in triumph on the 4th of August 1813. While this operation was in progress, Mariño effected the liberation of the eastern provinces of Venezuela, of which, excepting the fortress of Puerto Cabello, the patriots regained entire possession. At this period the whole authority in Venezuela centred in Bolivar as commander of the liberating army; and a convention of the principal civil and military officers, held at Caraccas on the 2d of January 1814, confirmed the dictatorial power which circumstances had placed in his hands. Misfortune, however, was at hand.

The contest, which had hitherto been confined to a species of partisan warfare, now assumed a more serious character. The royalists, effectually roused by the reverses they had sustained, concentrated all their means; and a number of sanguinary encounters ensued. At length, after various vicissitudes of fortune, Bolivar was defeated by Boves near Cura, in the plains of La Puerta, and compelled to embark for Cumana with the shattered remains of his forces. Caraccas was also retaken by the Spaniards in July; and before the end of the year 1814 the royalists were again the undisputed masters of Venezuela. From Cumana Bolivar repaired to Carthagena, where he once more appeared as a fugitive, and thence proceeded to Tunja, where the congress of New Grenada was sitting, in order to render an account of his operations. He had been unfortunate, which generally exposes a commander to misconstruction and obloquy; and his expedition, as brilliant in its outset as it proved disastrous in the issue, was severely criticised. But notwithstanding his misfortunes, and the efforts of his personal enemies, he was received and treated with great consideration; and as the congress were then organizing an expedition against Bogota, for the purpose of compelling Cundinamarca to accede to the general coalition of the provinces, Bolivar was intrusted with the command of the forces of the union on this occasion. Accordingly, in December 1814 he marched against Santa Fe at the head of 2000 troops. All attempts at negociation having failed, he invested the city, drove in the out-posts, carried the suburbs by storm, and was preparing to assault the grand plaza or square, where Alvarez and the troops of Cundinamarca were posted,

Bolivar. when the latter capitulated and acknowledged the general government of New Grenada, which was now transferred to Bogota. For this important service Bolivar received the thanks of the congress; and even the inhabitants of the city against which he had been sent expressed their approbation of his conduct.

In the meanwhile Santa Martha had fallen into the hands of the royalists, through the incapacity of Labatut; and as the general government appreciated the importance of recovering possession of that place, Bolivar was employed on this service, with orders to receive the necessary supplies and munitions of war from the citadel of Carthagena. But the preposterous jealousy of Castillo, the military commandant, defeated all his plans. The season for action was wasted in disgraceful altercations and ruinous delays; and while Bolivar was investing Carthagena, in the hope of intimidating Castillo into submission, Morillo landed on the island of Margarita at the head of an overwhelming force of Spaniards, and put an end to dispute. Finding a check thus effectually given to any movement against Santa Martha, and satisfied that he could not be usefully employed at Carthagena, Bolivar resigned his command, and embarked for Jamaica in May 1815. He remained at Kingston during the greater part of the year, whilst Morillo was reducing Carthagena and overrunning New Grenada almost without opposition; and in the interim narrowly escaped assassination by a Spaniard who had been hired to make an attempt on his life.

From Kingston Bolivar repaired to Aux Cayes in Hayti, where, assisted by private individuals, and furnished with a small force by Petion, he organized an expedition, in order to join Arismendi, who had raised anew the standard of independence in the island of Margarita. In May 1816 he reached Margarita, and sailing thence, landed on the continent near Cumana; but being attacked at Ocumare by the Spaniards under Morales, he was compelled to re-embark. Nothing disheartened by this failure, he obtained fresh reinforcements at Aux Cayes, and in December landed again in Margarita, where he issued a proclamation convoking the representatives of Venezuela in a general congress. He then proceeded to Barcelona, where he organized a provisional government, and assembled troops to resist Morillo, who was then advancing at the head of a strong division. The hostile forces encountered each other on the 16th of February 1817, when a desperate conflict ensued, which lasted during that and the two following days, and ended in the defeat of the royalists. Morillo retired in disorder, and being met on his retreat by Paez with his llaneros, experienced a new and more complete overthrow. Being now recognised as commander-in-chief, Bolivar proceeded in his career of victory, and before the close of the year had fixed his head-quarters at Angostura. But as the military operations of this and the following year belong rather to the history of Colombia than to the biography of Bolivar, the reader is referred to that head for an account of them. He presided at the opening of the congress of Angostura on the 15th of February 1819, when he submitted an elaborate exposition of his views on government, and also surrendered his authority into the hands of congress. Being, however, required to resume his power, and retain it until the independence of the country should be completely established, he re-organized his troops, and set out from Angostura, in order to cross the Cordilleras, effect a junction with General Santander, commanding the republican forces in New Grenada, and bring their united means into action against the common enemy. This bold and original design was crowned with complete success. In July 1819 he reached Tunja, which he entered, after a sharp action on the adjoining heights; and on the 7th of August he gained the victory of Bojaca, which gave him immediate possession of Santa Fe and all New Grenada. Nor was this all. By the resources of men, money, and munitions of war, which he found at Bogota, he was enabled to augment the effective strength of his army, and to return to Venezuela with a force sufficient to insure the expulsion of the Spaniards. Bolivar.

The campaign of New Grenada is unquestionably Bolivar's most brilliant achievement, and deserves much of the praise which has been lavished on it. His return to Angostura was a sort of national festival. He was hailed as the deliverer and father of his country, and all manner of distinctions and congratulations were heaped upon him. He availed himself of this favourable moment to obtain the enactment of the fundamental law of the 17th December 1819, by which the republics of Venezuela and New Grenada were henceforth united in a single state, under his presidency, by the title of the republic of Colombia. The seat of government was also transferred provisionally to Rosario de Cucuta, and Bolivar again took the field. Being now at the head of the most numerous and best appointed army the patriots had yet assembled, he gained important advantages over the Spaniards under Morillo, and on the 25th November 1820 concluded at Trujillo an armistice of six months, probably in the hope that the Spaniards would now come to terms, and that the further effusion of blood might be spared. If such were his views, however, they were disappointed. Morillo was recalled; Torre assumed the command; and the armistice was allowed to expire without any pacific overture being made. As a renewal of the contest was therefore inevitable, Bolivar resolved, if possible, to strike a decisive blow; and this accordingly he did at Carabolo, where he vanquished Torre, and so completely destroyed the Spaniards, that the shattered remains of their army were forced to take refuge in Puerto Cabello, where two years after they surrendered to Paez.

The battle of Carabolo may be considered as having put an end to the war in Venezuela. On the 29th June 1820 Bolivar entered Caraccas, and by the close of the year the Spaniards were driven from every part of the country except Puerto Cabello and Quito. The next step was to secure, by permanent political institutions, the independence which had now been conquered; and accordingly, on the 30th of August 1821, the present constitution of Colombia was adopted with general approbation, Bolivar himself being president, and Santander vice-president.

Having thus achieved the independence of his own country, Bolivar next placed himself at the head of the army destined to act against the Spaniards in Quito and Peru. The fate of Quito was decided by the battle of Pichincha, which was fought in June 1822, and gained by the conduct and prowess of Sucre. Bolivar then marched upon Lima, which the royalists evacuated at his approach; and entering the capital in triumph, he was invested with absolute power as dictator, and authorized to call into action all the resources of the country. But being violently opposed by some of the factions which then distracted Peru, and unable to make head against their intrigues, he was obliged to withdraw to Trujillo, leaving the capital to the mercy of the Spaniards under Canterac, by whom it was immediately occupied. This success, however, proved only temporary. By June 1824 the liberating army was completely organized; and taking the field soon after, it routed the vanguard of the enemy. Improving his advantage, Bolivar pressed forward, and on the 6th of August defeated Canterac on the plains of Junin; after which he returned to Lima, leaving Sucre to follow the royalists in their retreat to Upper Peru; an exploit which the latter executed with equal abi-

Bolivar. lity and success, gaining a decisive victory at Ayacucho, and thus completing the dispersion of the Spanish force. The possessions of the Spaniards in Peru were now confined to the castles of Callao, which Rodil maintained for upwards of a year, in spite of all the means that could be employed for their reduction. In June 1825 Bolivar visited Upper Peru, which having detached itself from the government of Buenos Ayres, was formed into a separate state, called Bolivia, in honour of the liberator. The first congress of the new republic assembled in August 1825, when Bolivar was declared perpetual protector, and requested to prepare for it a constitution of government.

We now come to what may be considered as the second part in the biography of Bolivar. Hitherto we have been almost exclusively occupied in tracing his military career; at first uncertain, and marked by great reverses, but afterwards illustrated by a series of victories which, although fortune frequently favoured his enterprises, were principally owing to his own courage and constancy, aided by very considerable military genius. But from the period at which we have arrived, he appears before us in the capacity of a lawgiver; and imputations on the purity of his political views, whether well founded or the reverse, seem to have been contemporaneous with his attempts to consolidate the governments which owed their existence to his military prowess. Our present business, however, is with facts. In December 1824 he convoked a constituent congress for the February ensuing, and this body assembled accordingly; but, owing to the unsettled state of the country, the dictatorial power was vested in Bolivar for another year, and a grant of a million of dollars was offered him, which, however, he declined. The congress soon adjourned, and the dictator remained absolute governor of Peru. There is no evidence that he abused the power thus intrusted to him. Residing partly at Lima and partly at Magdalena, he directed the acts of the government, and also proposed the celebrated congress at Panama for establishing an alliance between all the independent states of America. His project of a constitution for Bolivia was presented to the congress of that state on the 25th May 1826, accompanied with an address, in which he embodied his opinions respecting the form of government which he conceived most expedient for the newly-established republics. Of this code some account will be found in the article Bolivia; but its most extraordinary feature consisted in the provision for lodging the executive authority in the hands of a president for life, without responsibility, and with power to nominate his successor. This alarmed the friends of liberty, and excited lively apprehensions amongst the republicans of Buenos Ayres and Chili; whilst, in Peru, Bolivar was accused of a design to unite into one state Colombia, Peru, and Bolivia, and to render himself perpetual dictator of the confederacy.

And it must be confessed that the conduct of the liberator gave some colour to these imputations. By the surrender of the castles of Callao, Peru was completely freed from the Spaniards, and the object which Bolivar professed to have had in view was accomplished. Yet he manifested no intention of resigning his authority, and departing from the country. On the contrary, when the deputies for the constituent congress of 1826 assembled, they were induced to decline acting in their legislative capacity; whilst a majority of their number published an address, urging Bolivar to continue at the head of affairs for another year, and, in the meanwhile, requesting him to consult the provinces individually respecting the form of government which they would prefer, and the person who should be placed at its head. He complied with this request, which he had probably suggested; circular letters were addressed to the prefects of departments, commanding them to assemble the electoral colleges, and to submit for the sanction of these bodies a constitution similar in all respects to the Bolivian code; and this constitution was adopted by the colleges, which, with an unanimity perfectly extraordinary, nominated Bolivar president for life. We are too distant from the scene of these events, and too near the time of their occurrence, to be able to judge accurately as to the means by which this unanimity was produced in a country which, above all others, was distracted by factions, and a prey to intestine commotions. Bolivar.

In the meanwhile the affairs of Colombia had taken a turn which demanded the presence of Bolivar in his own country. During his absence Santander had administered the government ably and uprightly; its independence had been recognised by other countries; and its territory had been subdivided into departments, defined by geographical boundaries analogously to that of France. But Paez, who commanded in Venezuela, having been accused of arbitrary conduct in the enrolment of the citizens of Caraccas in the militia, refused obedience to the summons of the senate, and placed himself in a state of open rebellion against the general government; whilst the disaffected party, taking advantage of this collision, united with the refractory commander, and encouraged him in his opposition, by which means the northern departments became virtually separated from the rest of the republic. All, however, professed a willingness to submit their grievances to the decision of Bolivar, and equally required his return to Colombia. But the factious jarrings to which we have adverted did not rest here. Whilst these movements were taking place in Venezuela, various municipalities of the southern departments, which had originally constituted the presidency of Quito, held public meetings, at which the Bolivian code was adopted, and the supreme authority lodged in Bolivar as dictator. Whether these proceedings were in accordance with the wishes of Bolivar or not, it is impossible to affirm with any degree of certainty. It has been generally believed, indeed, that the meetings in question were summoned, and the resolutions suggested, by Leocadio Guzman, an emissary of Bolivar's; and some have even alleged that Paez was incited and encouraged by hints from the same quarter. But be this as it may, the actual state of affairs, however produced, was such as demanded the presence of Bolivar.

Accordingly, having intrusted the government to a council nominated by himself, with General Santa-Cruz at its head, he set out from Lima in September 1826, and hastened to Bogota, where he arrived on the 14th November, and immediately assumed the extraordinary powers which by the constitution the president was authorized to exercise in case of rebellion. He remained only a few days in the capital, and then pressed forward to stop the effusion of blood in Venezuela, where matters had gone on much farther than he could ever have contemplated, even supposing him to have been the main-spring of the intrigues to which we have already adverted. On the 31st December he reached Puerto Cabello, and the following day issued a decree offering a general amnesty. He had then a friendly meeting with Paez, and soon afterwards entered Caraccas, where he fixed his head-quarters, in order to check the northern departments, which had been the principal theatre of the disturbances. In the meanwhile Bolivar and Santander were re-elected to the respective offices of president and vice-president, and by law should have qualified as such in January 1827. In February, however, Bolivar formally resigned the presidency of the republic, at the same time expressing a determination to refute the imputations of ambition which had been so freely cast upon him, by retiring to private life, and spending the remainder of his days on his patrimonial estate. Santander

Bolivar. combated this resolution, urging him to resume his station as constitutional president, and declaring his own conviction, that the troubles and agitations of the country could only be appeased by the authority and personal influence of the liberator himself. But distrust and suspicion of Bolivar's conduct and intentions now filled all the friends of republican institutions. The anti-republican code of Bolivia was considered as a record of his political faith, and he was believed to be anxious for its introduction into Colombia. He was also accused of being in concert with Paez, and of having secretly fomented discord in the nation, in order to create an impression of the necessity of appointing him dictator. What truth there may be in these charges, or whether there be any at all, we shall not at present take it upon us to say. That they were generally believed at the time is unquestionable; nor is it easy, upon any other supposition, to account for the private intimacy which subsisted betwixt Bolivar and Paez, whilst publicly they were at open war, and fiercely denouncing each other. Another proof of the belief which then prevailed is the large minority in congress who voted for accepting his resignation of the presidency. But as a majority were of a contrary opinion, and insisted on his retaining the presidency, he repaired to Bogota to take the oaths and resume his functions. Before his arrival, however, he issued simultaneously three separate decrees; one granting a general amnesty of all past offences; another, convoking a national convention at Ocaña; and a third for establishing constitutional order throughout Colombia.

His arrival was accelerated by the occurrence of events in Peru and the southern departments, which struck at the very foundation of his power. Not long after his departure from Lima, the Bolivian code had been adopted as the constitution of Peru, and Bolivar had been declared president for life. This took place on the 9th of December 1826, the anniversary of the battle of Ayacucho; at which time the Colombian auxiliary army was cantoned in three divisions, one in Upper, and two in Lower Peru, at Arequipa and Lima. The third division, stationed at Lima, consisted of veteran troops, commanded by generals Lara and Sands, personal friends of the liberator. But notwithstanding their known attachment to Bolivar personally, his recent conduct in Colombia had rendered them distrustful of his designs; and although they had originally no disposition to thwart his views on Peru, had his ambition been confined to that state alone, they resolved to strike a blow against his power when they conceived it employed for the subjugation of their own country. Accordingly, in about six weeks after the adoption of the new constitution, a counter-revolution in the government of Peru was effected by this body of dissatisfied veterans. They had taken their measures so well that they arrested their general officers without opposition; placed them under the orders of Bustamente, one of their colonels; and announced to the inhabitants of Lima that their sole object was to relieve the Peruvians from oppression, and to return home to protect their own country against any attack on its liberties. Availing themselves of the opportunity thus unexpectedly afforded them, the Peruvians abjured the Bolivian code, deposed the council of ministers appointed by the liberator, and proceeded to organize a provisional government for themselves. After this bloodless revolution, the third division embarked at Callao on the 17th March 1827, and landed in the southern department of Colombia in April; part proceeding to Guayaquil, and part to Cuença and Quito, but all declaring that their only object in the step they had taken was the restoration of constitutional order, the preservation of republican institutions, and opposition to the designs entertained by Bolivar against the general liberty.

Intelligence of these events reached Bolivar while in the north of Colombia. He had long remained in a state of comparative inactivity; but the news of the counter-revolution in Peru, effected by the very troops in whom he had most implicitly confided, called forth all his energy, and he lost no time in preparing to march to the south, in order to reduce the refractory division. But he was spared the necessity of coming to blows with these troops, who, finding the government in the hands of the national executive, had peaceably submitted to General Ovando. In the meanwhile Bolivar had accepted the presidency, and resumed the functions belonging to his official station. But although Colombia was, to all external appearance, restored to tranquillity, the nation was divided into two parties, and agitated by their opposite views and incessant collisions. Bolivar had regained the personal confidence of the officers and soldiers of the third division; but the republican party, with Santander at their head, continued to regard with undisguised apprehension his ascendency over the army, and the political movements in which he was continually engaged, accusing or suspecting him of a desire to imitate the career of Napoleon. In the meanwhile all parties looked anxiously to the convention of Ocaña, which was to assemble in March 1828, for a decided expression of the national will. The republicans hoped that the issue of its deliberations would be favourable to their views; whilst the military, on the other hand, did not conceal their conviction that a stronger and more permanent form of government was essential to the public welfare, that the people were unprepared for republican institutions, and that Bolivar should be intrusted with discretionary power to administer the affairs of Colombia. Bolivar.

And the latter view seems to have prevailed. In virtue of a decree, dated Bogota, the 27th August 1828, Bolivar assumed the supreme power in Colombia, and continued to exercise it until his death, which took place at San Pedro, near Santa Martha, on the 17th December 1830. By this decree he was authorized to maintain peace at home, and to defend the country against foreign invasion, to command the forces of the state by land and sea, to negociate with foreign powers, to make peace and declare war, to enter into treaties, to appoint all civil and military officers, to issue decrees and ordinances of every description, to regulate the administration of justice, and in short to exercise all the functions and prerogatives of sovereign, not to say absolute power. The decree, indeed, provided that he was to be assisted in the exercise of the executive power by the council of ministers; but it is obvious, from the terms of this document, and above all, from the nature of the powers it conferred on the president, that, although the council might advise, it could never control him; and that, with the army at his back, he was sovereign of Colombia under a new denomination. Still his position was, in many respects, far from being an enviable one. Suspicion and distrust were excited by all his actions, and his life seems to have been embittered, if not shortened, by the incessant attacks made on his character and conduct. This seems evident from an address to the Colombian nation, which he dictated only a few days before his death; and in which, after alluding to his efforts in the cause of liberty, and asserting his disinterestedness, he complains that his enemies had abused the credulity of the people, and violated what to him was most sacred, his reputation; that he was the victim of his persecutors, who had brought him to the brink of the grave; that he had aspired to no other glory than the consolidation of Colombia; and that if his death should contribute to pacify all factions, and to strengthen the union, he would descend with tranquillity to the tomb.

Bolivia.

The time has not yet arrived when it would be either safe or just to attempt an estimate of Bolivar's real views and character. But there are some facts in his history which, as they seem to be well established, it is due to his memory to bring prominently forward. He expended nine-tenths of a splendid patrimony in the service of his country; and although he had for a considerable period unlimited control over the revenues of three countries, Colombia, Peru, and Bolivia, he died without a shilling of the public money in his possession. The value of his military services can best be estimated by their results. He conquered the independence of three states, which he also organized; and he called forth a spirit in the southern portion of the New World, which can never be extinguished. He purified the administration of justice; he encouraged the arts and sciences; he fostered national interests; and he induced other countries to recognise that independence which was in a great measure the fruit of his own exertions. (Restrepo's *Colombia*, vol. iii.; *American Annual Register*, vols. i. and ii.; *Encyclop. Americ.* v. Bolivar; *Memoirs of General Miller*, vol. ii.; Ducoudray Holstein's *Memoirs of Simon Bolivar.*) (J. B—E.)

Bolivia.

BOLIVIA.

This name was given in 1825 to a new state or republic in South America, formed from the provinces of Upper Peru, which formerly constituted part of the viceroyalty of Buenos Ayres, and were well known by the names of Charcas, Potosi, La Paz, Cochabamba, and Santa Cruz de la Sierra. These provinces, on securing their independence, soon after the battle of Ayacucho, 9th December 1824, found it necessary to come to a determination as to their future political state and institutions; and therefore it became a question with the inhabitants of Upper Peru, whether they should continue their former connection with the Buenos Ayrean or Argentine provinces, attach themselves to the republic of Peru, or form their country into a separate and independent republic. But the existing government of Buenos Ayres having with equal judgment and generosity divested itself of the claim which it had on the provinces of Upper Peru, the inhabitants of the latter were left at perfect liberty to decide on the future political government of their country. Deputies from all the provinces were in consequence nominated; and having assembled in Chuquisaca, the capital of the republic, in August 1825, the result of their deliberations was, that the provinces of Upper Peru should in future constitute a separate and independent nation. This assembly, continuing its sessions, issued a declaration of national independence; and in the exuberance of their gratitude to General Bolivar for the important influence he had exercised in accomplishing the liberation of their country, they determined on giving the name of Bolivia to the whole country.

Boundaries and divisions.

Bolivia extends from 9. 30. to 25. 40. of S. Lat., and from 58. to 71. of W. Long. from London, and it is bounded on the north by Peru and Brazil, on the east by Brazil and Paraguay, on the south by the Argentine provinces and Chili, and on the west by the Pacific Ocean and Peru. It has been divided by the constituent congress of Bolivia into six departments, viz. Potosi, Chuquisaca, La Paz, Santa Cruz, Cochabamba, and Oruro; and these have been subdivided into provinces and cantons. Thus each department includes in its jurisdiction certain provinces of the ancient regime. The department of Potosi contains Atacama, Lipez, Potosi, Porco, Chayanta, and Chichas; Chuquisaca contains Charcas or Chuquisaca, Cinti, Yamparaes, and Tomina; La Paz, the provinces of La Paz, Pacajes, Sicasica, Chulumani, Omasuyos, Larecaja, and Apolobamba; Santa Cruz, the provinces of Santa Cruz, Mojos, Chiquitos, Vallegrande, Pampas, and Baures; Cochabamba contains Cochabamba, Sacaba, Tapacari, Arque, Palca, Clissa, and Misque; and the department of Oruro, the provinces of Paria, Oruro, and Carangas.

Physical aspect of the country.

The province of Atacama, which belongs geographically either to Chili or Peru, forms the only part of Bolivia which comes into contact with the Pacific Ocean, and is situated between the Andes and the ocean. It is almost entirely desert and destitute of population. At its northern extremity is situated the small port of Cobija, which has been recently denominated Puerto la Mar, and has acquired additional importance from its being now the only avenue by which foreign articles of commerce can enter the Bolivian republic without the payment of transit duties; having obtained peculiar and valuable privileges, as an encouragement to the introduction of merchandise by this route, in preference to the more convenient routes by the Puertos Intermedios, belonging to the republic of Peru. But the arid nature of the surrounding country, and the great scarcity of water, must greatly retard its advancement, as the inhabitants are not only scantily supplied with this very essential necessary of life, but the mules employed in the transportation of goods into the interior are exposed to great privations and hardships from the want of water and pasture.

The provinces of Lipez, Porco, Potosi, Chichas, Oruro, Paria, Carangas, and some others, are very elevated districts, and principally valuable on account of their mineral riches. The climate is so cold that scarcely any vegetable productions present themselves, except a species of coarse grass, which serves as pasture to the numerous herds of *llamas*, *guanacos*, *alpacas*, and *vicuñas*, which abound in these elevated situations. Cinti, Yamparaes, Tomina, some parts of Chichas, and other places, enjoy a milder climate, and the vegetation is more abundant and varied; while from these the mining districts are principally supplied with provisions and other necessaries. In the provinces of Chayanta, Larecaja, Sicasica, Chuquisaca, and other places in the department of La Paz, there are also numerous and valuable mines of gold and silver; but the nature of the country being more diversified and less elevated in many places, the inhabitants are less dependent on the neighbouring provinces for their supplies. The greater number of the eastern provinces, which belong to the departments of Cochabamba and Santa Cruz, are of less elevation, and consequently possess many of the productions peculiar to tropical regions. The province of Tarija, which is situated at the south-eastern extremity of the department of Chuquisaca, and which belongs politically to the Argentine republic, forms geographically a part of the Bolivian republic, and was at one period claimed and taken possession of by them as such. This quarter has always been described as possessing a delightful climate, with a rich and fertile soil.

Mountains.

The greater part of the republic of Bolivia is situated in a mountainous and elevated country, more particularly at its western and central parts; but towards the east it becomes much less so, and at length terminates in extensive plains, which are bounded on the east by the Brazils. That part of the Andes which is situated in Bolivia is divided into two separate chains, of great elevation, running in a northerly direction, and nearly parallel to each other. Their separation commences near Potosi, in the province of Porco, between 19° and 20° of south

Bolivia. latitude, and they continue apart from each other, forming the eastern and western Cordilleras of Bolivia, and terminate by their union, between 14° and 15° of south latitude, to the south of the city of Cusco. These lofty ranges inclose an extensive valley or table-land, which has no visible outlet for the discharge of its waters; in this respect resembling the valley of Mexico before the formation of the artificial outlet denominated the Desagua de Huehuetoca. The former, however, greatly exceeds the latter in extent, as well as in elevation. From Carangas at its southern extremity, in 19° 45′, to Lampa, in 15° S., its extent has been estimated at about 3500 square leagues; and the barometrical observations of Mr Pentland give it an elevation above the level of the sea, at Oruro, the lowest point of observation, of no less than 12,441 feet. The mountains of the western Cordillera vary in elevation from 13,605 feet, which has been observed at El Paso del Alto de los Huesos, to that of 18,898 feet, which is attained by the Cerro de Tacora or Chipicani. In this chain are found several active volcanoes, amongst which may be enumerated those of Shama and of Arequipa, the latter of which presents to the observer the most perfect natural cone which has yet been observed in any country. The eastern Cordillera, which is entirely confined to Bolivia, has been ascertained, by the trigonometrical observations of the same gentleman, to possess an elevation greatly exceeding that of Chimborazo, or of any other mountain in the New World. Thus he has found that the summit of the Cerro Nevado de Sorata has an elevation of 25,250 feet, and that of the Cerro Nevado de Illimani, situated to the eastward of the city of La Paz, an elevation of 24,350 feet above the level of the sea.

From that part of the eastern Cordillera which is situated between Oruro and La Paz, in about 18° of south latitude, there branches off a chain, which proceeds from west to east, constitutes the mountains of Cochabamba and Santa Cruz de la Sierra, and is called, in the different parts of its course, the Cordillera de Chiriguanaes, de los Sauces, and de Yuracarees, each rising to the region of perpetual snow. Their eastern declivity is very rapid, and their loftiest summits are situated, not in the centre, but in the northern part of the group. This lateral ridge, where it terminates, forms the point of partition between the basin of the Amazons and that of the Rio de la Plata. The Cachimayo and the Pilcomayo, which rise between Potosi, Talavera de la Puna, and Chuquisaca, flow to the south-east to unite with the Parana; while the Parapiti and the Guapey or Rio de Misque pour their waters into the Mamori towards the north-east, and thence into the Amazons. But the ridge of partition being placed near Chayanta, between 19° and 20° south latitude, and south of Misque, Tomina, and Pomabamba, the river Guapey, which flows through these provinces, is forced to sweep round the whole group or chain of Cochabamba in order to reach the plains of the Amazons. From that part where this chain of mountains closes the ridge of partition of Cochabamba, it proceeds towards the north-east to 16° of south latitude, and forms, by the intersection of two plains slightly inclined, a kind of wall in the midst of the savannahs, which separates the waters of the Guapore, flowing into the Madeira, from those of the Aguapehy and Jauru, tributary streams of the Rio Paraguay, and thus forms a line of junction between the lateral Cordillera or counterfort of Cochabamba and the mountains of Brazil. This level strait, which divides the sources of the Mamori and the Pilcomayo, and crosses the provinces of Mojos and Chiquitos, displays bare and grassy steppes, like the plains of Casanare and Buenos Ayres.

Lakes. The valley or table-land which is occupied by the lake of Titicaca and the Rio Desaguadero forms the most elevated table-land in the globe, with the exception of that of Thibet, which presents only mountain pastures, Bolivia. covered with sheep; while this table-land of the New World presents towns and populous cities,—affords support to numerous herds of cattle, *llamas*, *guanacos*, and sheep,—and is covered with harvests of maize, rye, barley, and wheat, at an elevation which has nothing to equal it in any other part of the world. The lake of Titicaca or Chuquito, which occupies its northern extremity, is 12,703 feet above the level of the sea, and its extent is equal to twenty times that of the lake of Geneva, or 448 square marine leagues. It is surrounded by numerous towns and villages, with a rich and fertile country, and contains several islands, the largest of which is called Titicaca, and was long held in great veneration by the Peruvian Indians, in consequence of its having been the place from whence Manco Capac and his consort Manco Oello Huaco, the great founders of the empire of the Incas, issued, to spread civilization, industry, and good government among the surrounding nations; in memory of whom, and as a testimony of gratitude for so many benefits conferred upon the country, the Incas afterwards erected in this island a magnificent temple to the sun, in which were accumulated great riches in silver and gold, being offerings of the Peruvians, all of which were afterwards thrown into the lake, to prevent their falling into the hands of the Spaniards. This island has in latter times fallen sadly from its former high destinies; since, during the revolutionary war, it served the purpose of a secure prison, in which were confined the patriot prisoners who had had the misfortune to fall into the hands of the royalists. The lake of Titicaca is very irregular in its form, but it has been estimated at about 240 miles in circumference; in many places it has a depth of seventy or eighty fathoms, and admits of extensive navigation for ships and smaller vessels, though not unattended with danger, as it is subject to sudden storms and violent gusts of wind from the neighbouring mountains. This forms the most elevated scene of navigation perhaps in the universe. This lake communicates with the smaller lake of Paria, situated at the southern extremity of the valley, by means of the Rio Desaguadero, which flows out of the lake of Titicaca, and has a breadth of from eighty to a hundred yards. This river and lake form part of the western boundaries between the republics of Bolivia and Peru. Over this river was formed, in the time of the Incas, a suspension bridge, composed of cables and cords made of the grass and rushes which grow on its borders; and the work was constantly renewed from time to time, to obviate the effects of decay, as it constituted the only line of communication between the opposite sides of the valley. These lakes, with the Desaguadero, form the only recipients for the water of those rivers and streams which arise from the surrounding mountains and enter into this extensive plain, which has no visible outlet, by which any portion of its contents can escape, otherwise than by means of evaporation.

Rivers. Those rivers which take their rise from the western declivity of the western Cordillera, and flow into the Pacific, are so inconsiderable in magnitude, and so short in their course, as scarcely to merit observation, and are only useful in supplying the means of a partial irrigation to the arid plains which separate these mountains from the Pacific. But those numerous rivers taking their origin on the eastern declivity of the more elevated or eastern Cordillera, which is distinguished in the different parts of its extent, as the Cordillera of La Paz, of Palca, of Ancuma, and of Pelechuco, present a very different aspect, and are of much greater importance, since they communicate with large navigable rivers, which terminate in the Atlantic Ocean.

The river Paro or Beni, which takes its origin in the

Bolivia. neighbourhood of the city of La Paz,—and the Guapey, which arises near Cochabamba, and, sweeping round the southern and eastern bases of the Cordillera of Cochabamba, unites itself to the Mamori,—flow to the north-east to mingle with the waters of the mighty Marañon or Amazons; while the Pilcomayo, which arises near Potosi and Chuquisaca, and the Vermejo, which has its origin in the valley of Tarija, bend their courses, at a considerable distance from each other, to the south-east, until they mingle their contents with those of the Paraguay, which terminates in the Rio de la Plata. All these rivers are navigable throughout their whole extent, until within a very inconsiderable distance of the important cities above mentioned; and not only afford the most convenient and extensive lines of river communication with the nations of Europe and all the countries which border on the Atlantic, but will likewise, in time, by means of steam navigation, open up the vegetable wealth of the intermediate districts.

Animals. The animals which distinguish the more elevated parts of Bolivia are the *guanaco*, the *llama*, the *alpaca*, and the *vicuña*, which are found in great abundance in such situations. These animals, in their structure and habits, are all closely allied to the camel of Africa. Thus, an examination of the structure of the stomach shows that they are capable of existing during a considerable time without any supply of water, and in fact they are seldom seen to drink from the streams of their native mountains. The camel seems peculiarly well calculated to live in the arid and burning deserts of the Old World, and the form of its feet is singularly adapted for traversing rapidly these extensive plains; whilst, on the other hand, the *guanaco* and the *llama* have their feet so constructed as to enable them with facility to ascend and descend the abrupt declivities, and to traverse the rugged and uneven passes, which abound in these mountains. They seem likewise to frequent particularly those parts of the Cordillera of the Andes which are the most dry and arid, and which are least clothed with dense forests and shrubbery. Thus, in the Cordillera which separates the Argentine republic from Chili, the *guanacos* are found in great numbers on the summits and eastern declivities, which are exceedingly arid and bare, when compared with the western or Chili side, where the Andes in their whole extent are clothed to a certain elevation with a broad belt of forest trees and evergreens, and where, at certain seasons of the year, there are heavy and continued rains. On this side the *guanaco* is of comparatively rare occurrence.

There has existed considerable diversity of opinion among naturalists whether the *guanaco*, *llama*, *alpaca*, and *vicuña*, are different, or only the same species: but it is now the prevailing opinion that they comprise two distinct species, the three former constituting one, the *Camelus Llama* of Linnæus, or *Auchenia Glama* of Illiger; and that the differences which have been observed are only the results of domestication,—the *guanaco* being the animal in its wild or native state, the *llama* the same animal after it has been modified by a long period of domestication, and the *alpaca* only differing from the *llama* in being covered with a more abundant fleece, and kept in flocks for the sake of the wool. The subject, however, of the identity of these animals requires some further investigation, as it has been asserted that the distinctive types of the different kinds may yet be discovered in a wild state. In their natural state, the *guanacos* are found in numerous herds on the more elevated parts of the Andes, Peru, and Bolivia, and of the Cordillera which separates Chili from the Argentine provinces, and extend even a great way along that chain as it approaches the Strait of Magalhaens, having been met with in considerable numbers, according to the testimony of Captain King, in various parts of the islands composing Tierra del Fuego, at a distance of only fifty miles from Cape Horn They are likewise found in the Andes of Colombia or New Grenada, but are there much less numerous. In the summer they usually frequent the most elevated parts of the mountains; but on the approach of winter, the snow and the inclemency of the season obliges them to seek shelter in the valleys and plains below. They are then in high condition, and at this season are most prized by the hunters. The young of the *guanaco* are easily tamed, and soon become remarkably gentle and attached to their keepers. Bolivia.

These were the only ruminating animals found in South America on its discovery by the Spaniards; and the *llamas* were then extensively employed as beasts of burthen by the Peruvian Indians;—a custom which is still continued to a considerable extent, in consequence of the greater facility and economy in feeding them. But, in many instances, the introduction of horses and mules has entirely superseded the use of them. They are capable of carrying a load of from 100 to 150 lbs., which they convey, at the rate of fifteen, and sometimes even of twenty, miles a day, over rocks and precipices where their attendants can sometimes with difficulty follow them; and they require very little care to direct them in their course. The larger species are capable of carrying a full-grown man, and will trot or run under him with great swiftness for several miles. The chief merit of the *llama*, next to its being sure-footed, seems to be its extreme docility, and the trifling expense of its maintenance. "They want neither bit, bridle, nor saddle," says Feuillée; "there is no need of oats to feed them; it is only necessary to unload them in the evening at the place where they are to rest for the night; they go abroad into the country to seek their own food, and in the morning they return to the same place; their baggage is replaced, and they continue their route." Their defects are, their comparative weakness, their slow rate of travelling, and their obstinacy. If their load is too heavy, if they are fatigued, or are urged forward too fast, they lie down and refuse to proceed. It is therefore requisite to have a number of spare *llamas* in readiness to supply the places of such as are fatigued or give in; for after four or five days' travelling they generally require to rest.

The *guanaco*, and the *llama*, which is considered as of the same species, but only in a domestic state, are exceedingly graceful and handsome animals; and their whole physiognomy indicates vivacity and intelligence. They usually march two and two when in troops, in a stately manner, with their heads erect; and it is a remarkable circumstance, that the *llamas*, in passing underneath an archway to which they are unaccustomed, always bow their heads, however high the arch may be. In their wild state, when disturbed by the approach of strangers, these animals seem to possess a considerable degree of curiosity, placing themselves on the summits of the neighbouring mountains, and gazing upon the intruders beneath, occasionally uttering a peculiar interrupted cry, after which they scamper off to a distance. They are remarkably gregarious, and may sometimes be seen in herds of from 300 to 500; and when disturbed, or when travelling in the mountains, they constantly follow a leader—a circumstance of which the hunters who lie in wait for them frequently take advantage. The *llamas* are so exceedingly tame and gentle in their manners, that in passing along the streets or roads they occasionally approach their heads towards the bystanders, as if requesting corn or some other article of food: when irritated, however, the *guanaco*, in its tame state, as well as the *llama*, squirts on the aggressor some saliva from a cleft in the upper lip; but our own experience has proved to us that this saliva is quite destitute of that acrid quality which some have attributed to it. On the arrival of the Spaniards in Peru these animals were killed in vast num-

Bolivia. bers for their flesh and skins. Gregorio de Bolivar estimates, that in his time 4,000,000 were annually killed to be eaten, and no less than 300,000 *llamas* were employed in the transport of the ores from the mines of Potosi alone. Even at the present day the *guanaco* or wild species exists in great numbers in those parts of the Andes which are least frequented; yet many are still annually destroyed and eaten by the Indians, and also by the *puma* or American lion, which is found in many parts of these mountains. Their flesh is savoury when young, but not very palatable when full grown; their wool, however, is very valuable to the Indians, who manufacture it into hats and various kinds of woollen stuffs; and their skins, when tanned, are useful in making shoes and harness.

The *vicuña* (*Camelus Vicugna*) is a smaller animal than the *guanaco* or *llama*, and only useful for its fleece. The wool is long and fine, and forms a valuable article of commerce; it is of a brownish colour, somewhat resembling that of a dried rose leaf; it has a soft, silky, and close texture, and is well calculated for the manufacture of hats and warm clothing. The *vicuña* very much resembles the *llama* and *guanaco* in its habits and dispositions, but cannot be usefully employed as a beast of burthen. It usually frequents the highest parts of the mountains, even where frost and snow prevail. It is extremely timid, but gregarious, and runs very swiftly. The *chinchilla* (*Chinchilla lanigera*) is also an inhabitant of the mountainous parts of Bolivia. The skins, however, are of an inferior quality, although larger than those obtained from the northern parts of Chili; but still they form a very valuable article of commerce, on account of the great fineness and delicacy of their furs. The eastern or more thickly wooded parts of Bolivia are inhabited by a variety of wild animals, which are more or less common in Brazil, and the other parts of intertropical America of inconsiderable elevation.

Vegetation. The vegetation of Bolivia is exceedingly various, depending principally upon the elevation of the district above the level of the sea. In many situations the mountains are covered with perennial snows, below which level we find those extensive plains or *paramos*, on the less elevated parts of which are situated the cities of Potosi, Oruro, and other towns in the district of Charcas. On these vegetation is very slight and scanty, consisting principally of a coarse wiry grass called *ichu*, and rushes, which only serve the purpose of food for the *llamas*, *guanacos*, *alpacas*, and *vicuñas*, which abound there; and during long journeys, as from Oruro to La Paz, scarcely a tree is to be seen. In the more sheltered spots may be found some stunted bushes of the carob tree, and another shrub called *tola*. Several species of the *cactus* tribe are also found in these elevated regions, and especially the *Cactus Peruvianus*, so general an inhabitant of South America, where it sometimes grows to the height of from twenty to thirty, or even forty feet, and is either in single stems or variously branched. It is used in many parts of Bolivia as a fence for inclosures; and the stems, when divested of their spines, are employed in the formation of rafters and door-posts for houses. Descending in level, as on the margins of the lake of Titicaca and at La Paz, the vegetation becomes more vigorous and varied, and the plains may be seen covered with abundant crops of grain; while in the neighbourhood of La Paz is cultivated to a great extent the coca plant (*Erythroxylum Coca*), in such general use, and so essential an article with the Indians, that its culture in the province of La Paz is productive of great wealth to the inhabitants of that part of the country. It is used by them as a masticatory in combination with a particular alkaline substance, called *llipta*, and on long and painful journeys serves the Indian in lieu of all other nourishment. In the neighbourhood of Chuquisaca and Cochabamba, which have respectively an elevation of 9331 and 8448 feet above the level of the sea, and in numerous other valleys, the vegetation is so rich and luxuriant, that they are considered as the gardens of Bolivia, and supply the more elevated mining districts with a great part of those necessaries and luxuries of life which their more rigorous climate denies them. As the country descends towards the east, the sides of the mountains become clothed with dense forests, and at length present all the exuberant richness and variety which characterize the vegetation of level districts within the tropics. Bolivia.

Geology. The geological structure of the colossal mountains situated in Bolivia has hitherto been very imperfectly examined. We learn from Humboldt, however, that the metalliferous mountains near Potosi are principally composed of trachytic porphyries; and Mr Pentland likewise discovered trachyte in the mountain of Pichu, one of the most elevated of the western Cordillera. In the same chain there likewise exist various volcanic mountains, some of which are in an active state. There is perhaps no part of the world which affords a more interesting field for the investigations of industrious and intelligent geologists than Bolivia, not only on account of the great elevation which it attains, but also from the exhibitions of internal structure presented by volcanic agency and otherwise; while powerful aid might be afforded by such inquiries in searching for mines, and in the prosecution of mining enterprises, and also in discovering beds of coal and other important auxiliaries, tending to lessen the difficulty and expense of such undertakings.

Minerals. The great variety, extent, and value, of the mineral productions of the mountainous districts of Bolivia have given to this part of America an importance and celebrity which it would not otherwise have obtained, and caused large and populous cities and towns to be built at elevations where the rigours of the climate and the deficient vegetation would otherwise have afforded very few inducements for fixing the abodes of industry.

Gold. Gold is found in considerable quantities in the mountainous parts of Bolivia; but, owing to the expense of extracting the metal from the ore, the mines which produce it have not been worked to the extent of which they are susceptible. In these it is usually found in the form of grains or nodules, or intermixed with antimony, silver, and other substances, and is separated by reducing the whole to a fine powder, and by amalgamation with quicksilver. The colossal mountain of Illimani is believed to contain great quantities of gold, in consequence of that metal having been found in a native state in considerable quantities in the lake of Illimani, situated at its base, and at an elevation of 15,780 feet above the level of the sea. In the seventeenth century, likewise, an Indian found near its base, at a short distance from the city of La Paz, a mass of native gold, which was said to have been detached from the mountain by the agency of lightning, and which, having been purchased for the sum of 11,269 dollars, was afterwards deposited in the cabinet of natural history at Madrid.

But by far the greater part of the gold procured in Bolivia is obtained by means of the *lavaderos* or gold washings, in the beds of rivulets, where it is found in the form of grains. The most productive of these are the celebrated *lavaderos* of Tipuani, consisting of streams descending from the snow-capped summits of the Cordillera of Ancuma, situated about sixty leagues to the north-east of the city of La Paz, in the province of Larecaja. The town of Zorata, which is the great resort of the miners and all others who are attracted by these gold washings, is at a considerable distance, and is reached by a road full of difficulties and dangers. The eastern sides of the mountains, when contrasted with the western declivities,

Bolivia. looking towards the lake of Titicaca, present a rich and vigorous vegetation, and the climate becomes sensibly milder as we descend. The waters rush with impetuosity from these lofty mountains, and, accumulating greatly in their progress, at the distance of fifteen miles from the summit called Amicarpa, form the river Tipuani, which runs with great rapidity, and, passing between two lofty mountains, emerges, after a course of about forty miles, near the village of Tipuani, where it loses its former rapidity, the country now consisting of only gentle undulations. This river terminates in the Beni, one of the tributaries of the Amazons; but before reaching the Beni its channel ceases to be productive of gold. From its inconsiderable elevation, the country where these *lavaderos* are situated is hot and moist, and subject to intermittents. The surrounding country is covered with a very luxuriant vegetation, and teems with all the animal and vegetable productions of tropical America.

The gold is found in the form of grains or *pepitas*, at the depth of ten or twelve yards below the surface, imbedded in a stratum of clay of several feet in thickness, and has the purity of 23½ *quilates*. All the operations are performed by manual labour, and the excavations are kept free from water by means of buckets, at an expense of labour which might easily be saved by the employment of pumps and other mechanical contrivances. An idea may be formed of the disadvantages of pursuing such a course by stating, that at the works of Isola alone, in the years 1819, 1820, and 1821, no less than from 300 to 400 labourers were constantly employed in emptying the water by means of hide buckets; yet the gold-washings were so productive as not only to cover the heavy expense thus incurred, but greatly to benefit the proprietor. The gold-washings at Tipuani were worked in the time of the Peruvian Incas, as is evinced by their tools, which are occasionally found imbedded in the alluvial soil, and almost invariably in such situations as prove the most productive.

Silver. Silver, however, has hitherto been the staple metallic production of Bolivia, and has given to it that celebrity which it has long possessed. In the rich mountain of Potosi alone, according to the records kept at Potosi of the *quintas* or royal duties from the year 1545 to the year 1800, no less than 823,950,509 dollars were coined during that period; and if to this be added the amount of the preceding years, not included, and that obtained in a clandestine manner, without the payment of the customary dues, not less than 1,647,901,018 dollars have been obtained from this source alone in the space of 255 years.

The Cerro de Potosi, or argentiferous mountain of Potosi, has somewhat of a conical form, resembling a colossal sugar-loaf; its base being about three leagues in circumference, and its summit 16,037 feet above the level of the sea, and 2723 above the level of the great square or *plaza* of the city of Potosi, which is situated at its base. At the foot of the *cerro* is a smaller mountain called Huayna Potosi, or the Younger Potosi, likewise containing silver, but in less abundance than the other, and less accessible, from the numerous springs which there impede the operations of mining. The principal mountain has been worked as high up as within 125 feet of its summit. The labours of the miners have hitherto been principally confined to the upper half of the mountain, which has been perforated by numerous excavations, with at least 5000 *bacas minas*, or opening of mines. This number, however, does not indicate the existence of so many mines, since each mine has often two or more openings. These operations have not been conducted with any regard to order or convenience. The upper part of the mountain is exhausted to a considerable extent of its valuable contents; but the lower part is still in a great measure untouched, as the springs are there more numerous, and the water accumulates in such quantities as Bolivia. materially to interrupt the further progress of the miners. Various works have been commenced and prosecuted, for carrying off these waters from the lower part of the mountain, but none of them have ever been carried to such an extent as fully to answer the purpose of their formation. The most extensive of these has been the *Socabon* or adit of San Juan Nepomuceno, in the formation of which the Spanish government expended no less a sum than 560,243 dollars. It is 2200 *varas* or yards in extent, six feet in height, and six in breadth at the base, and it is arched and lined with rough stones without cement. In various parts of the country near the mountain are numerous lakes or pools formed from the water of these springs and other sources in the mountains, which, being economized, give motion to the machinery employed in reducing the ore.

The mines of Potosi, according to Humboldt, rank next in importance to those of Guanaxuato in Mexico. The existence of silver in this place was first accidentally discovered by an Indian in the year 1545, and ever since that time its mines have been worked. A few years prior to the commencement of the revolution it was worked to a considerable extent, and no less than 40 *ingenios* or mills for grinding ore were in full operation; but the events which followed proved most destructive, not only to the machinery employed, but likewise to the capital embarked in mining operations. From fifty to sixty *bocas minas* were worked in 1825, when General Miller became prefect of the department; but Temple, when he visited it soon afterwards, found only about fifteen *ingenios* at work, affording on an average 1500 merks of silver weekly, or about L.125,000 sterling per annum. Pazo, in his *Letters on South America*, on visiting the mountain of Potosi, thus expresses himself: "The sublimity of the surrounding scenery did not so much interest my feelings as the celebrated mountain which has poured forth its *lavas* of silver upon the world, to animate enterprise and reward industry; to pamper the luxurious, and minister to the comforts of the sober and virtuous; to disseminate knowledge and religion, and to spread the desolations of war, marshalling armies in the field, and pointing the thunder of navies on the ocean; filling cities with monuments of taste and art, and overwhelming them with ruin; founding mighty empires, and levelling them with the dust; inciting, in short, to virtue and to crime, and being the source of much good, and the root of great evil, in the world."

The silver mines of Portugalete, in the province of Chichas, have acquired considerable celebrity on account of the richness as well as quantity of their ores, which yield from 60 to 80 merks of silver to the *caxon*, while those of Potosi only afford about 10 merks from the same quantity of ore. The silver mines of Choromo, near Tupiza, in the province of Chichas, were worked, until lately, on account of General Olañeta, the proprietor, and were considered as productive. Besides these there are various other silver mines in the province of Chichas, but their value is much diminished by the scarcity of water, and their being situated in an almost desert and unproductive country. At La Plata, Porco, and Lipes, there exist silver mines, especially one in the latter province, celebrated for the purity of its ores, which were formerly in great repute, but since eclipsed by the more important ones of Potosi and of other places. In Carangas there are rich mines, where the silver is found in its metallic state, disseminated in the rock, a kind of ore which is considered as very productive. At Oruro the silver mines were formerly very rich and productive, as the opulence of its inhabitants, of which there are some remarkable instances on record, sufficiently

Bolivia. evinced; but these, as well as the celebrated tin mines of the same place, have fallen into decay, principally in consequence of the disastrous events which attended the insurrection of Tupac Amaru. They are now filled with water, and the inhabitants being deficient in the requisite machinery, have no means of emptying them. Besides those already enumerated, many other gold and silver mines were worked to advantage; but in consequence of the diminished confidence and capital resulting from the long and disastrous war of independence, they have latterly been neglected.

Timber or coal for smelting is a great desideratum in Potosi and others mining districts, as, from the nature of the ores, in which the silver is principally associated with copper and lead, they are unsuited for the process of amalgamation, and can only be properly extracted by fusion, by which means the copper and lead are also preserved. The loss of mercury, in extracting the silver by the process of amalgamation from the ores produced in the mines of Bolivia and Peru, is from 15 to 25 per cent. on the value of the silver produced; while, by the process of smelting, all the silver might be obtained at an eighth part of the expense, in a tenth part of the time, and with infinitely less labour, and great quantities of lead and copper at the same time preserved.

The methods hitherto employed for the reduction of the silver ores of this country are exceedingly imperfect and inefficient; the manipulations are tedious, operose, and expensive; and a considerable proportion of the silver is entirely lost in its extraction by means of amalgamation, while much of the mercury is also unnecessarily wasted. But great advantages may be expected to arise from the introduction of improved methods of mining and metallurgy. These mines can never be worked to advantage in the manner which has of late been so generally followed. More skill and capital are requisite to render them productive and remunerating.

Roads. The roads which form the means of communication between Bolivia and the surrounding countries, and between the various provinces of the same republic, are in no respect commensurate to the important purposes which they are destined to serve. By inattention to the formation and preservation of roads, the Spaniards and their descendants have fallen greatly behind the Peruvians, whose industry and civilization they affected to despise, and laboured hard to depreciate. We have the testimony of a late observer, that the most distinct traces of an ancient Peruvian road may be observed at the present day as far south as the valley of Uspallata, in 32 degrees of south latitude; and there is little doubt that it was continuous with that formed between Potosi and Cuzco, since the inhabitants of the provinces of Mendoza, San Juan, and La Rioja, which are situated along the eastern base of the Cordillera of the Andes, separating Chili from the Argentine provinces, are in the constant practice of conveying to the upper provinces of Peru their wines, brandies, dried fruits, and mules, by this mountain route, which is distinguished by the name of El Despoblado. Those persons who are in the habit of travelling by this route describe it as by no means difficult, since, with only occasional interruptions, it proceeds along longitudinal valleys, running north and south in a direction parallel with the Cordillera; and it has been remarked by Andrews, a recent traveller in Bolivia, that there is another road distinct from that by Jujuy, which might easily be made passable for carriages, from Salta to Tupiza and Potosi, and even to Cuzco, and which is only distant twelve leagues from the one presently in use between Potosi and Jujuy,—a miserable tract, incapable of being passed except on mules and horses, and in many places not only difficult, but dangerous. The present route, for Bolivia. it can scarcely be designated by the name of road, from Potosi to Jujuy, the first city belonging to the Argentine republic, is about 310 miles in length; and this place forms the point where a road commences for carriages and waggons as far as Buenos Ayres, an additional extent of land carriage of about 1617 geographical miles. The various routes from Bolivia to the coast of the Pacific, by the way of Cobija or Puerto Lamar, Tarapaca, by Oruro to Tacna and Arequipa, can only be passed on mules or horseback; and travellers are sometimes exposed to great perils and hardships from exposure to those storms which occasionally prevail at such great elevations. The President Ballivian, however, while in office, did much to obviate these difficulties, and initiated a new era of things by the construction of a splendid highway, which leads from Sucre, and passing Santa Cruz connects Moxos and Chiquitos and the fertile plains of the Beni and Madera. Other roads of equal magnitude and importance are now in course of formation.

Climate. The climate of Bolivia is exceedingly various, being principally dependent upon the proportional elevation of the district above the level of the sea. In some parts the mountains are covered with eternal snows, below which are extensive plains or *paramos* destitute of vegetation, where the climate is cold and rigorous. Here travellers are frequently exposed to great danger and hardship, owing to the storms that occasionally prevail, especially snow storms, which, besides other inconveniences, frequently produce the *surumpi* or snow blindness, an affection which has proved fatal to some travellers, and to many of the brave and energetic men employed in the late eventful struggle for independence. On the less elevated of these plains are situated the cities of Potosi, Oruro, and others. The climate of Potosi, at an elevation of from 13,314 to 13,668 feet, is disagreeable, and so various that in one day it frequently exhibits the vicissitudes of the four seasons of the year. Thus, during the night and the early part of the morning it is piercingly cold; in the forenoon it resembles our fine weather in March; in the afternoon the rays of the sun, in so pure and attenuated an atmosphere, are very powerful, and scorchingly hot; while towards evening the air usually becomes mild and serene. Europeans and the Creoles therefore require to be well clothed; but the Indians, who are inured to the climate from early infancy, seem less susceptible of its effects, and enjoy good health with inferior clothing. Strangers, on first arriving in this country, are usually affected with difficulty of breathing, owing to the extreme rarity of the atmosphere; they are likewise frequent sufferers from dysentery, which, however, for the most part soon disappears, and then they enjoy tolerably good health. Here no inconvenience is experienced from troublesome insects. The climate of Oruro, which has an elevation of 12,441 feet above the level of the sea, is likewise cold, but by no means unhealthy. From its sheltered situation, the city of La Paz, at an elevation of 12,195 feet, enjoys a mild and pleasant climate; but that of Chuquisaca, with 9331, and Cochabamba, with 8448 feet of elevation, are universally admitted to be the most delicious and agreeable places in Bolivia. In descending through the eastern provinces, towards the plains of Mojos and Chiquitos, are experienced all the gradations of climate, from the mildness of Chuquisaca to the temperature which characterizes the equinoctial regions of America, where intermittent fevers, dysenteries, and other diseases peculiar to warm climates, are found to prevail.

Commerce. The only productions hitherto furnished by Bolivia as articles of commerce have been the precious metals, which were exchanged for various articles of luxury and necessity. The rude and simple fabrics manufactured by the Peruvian Indians are usually appropriated to their own

Bolivia. domestic uses; while the valuable vegetable productions, and the herds of cattle and mules, which are reared in the eastern parts of the republic, have hitherto scarcely been sufficient for the supply of the inhabitants of those populous mining districts, that are principally dependent on them for subsistence. Coca to the value of 200,000 dollars is annually exported from La Paz to other parts of Bolivia and Peru.

Before the revolution a very extensive traffic was maintained between the upper provinces of Peru and the provinces of the Rio de la Plata, for supplies of cattle and mules. These were reared in great numbers in all the interior Argentine provinces, expressly for the use of those countries, and were first sent by easy journeys to the luxuriant pastures of Salta and Jujuy, where they were carefully fed and tended during the winter, previous to their being conveyed to their final destination in Bolivia and Peru. Some idea may be formed of the extent of this traffic by stating, that besides all those furnished by the other Argentine provinces, the province of Salta alone supplied annually to Upper and Lower Peru from 60,000 to 80,000 mules, on all of which they realized considerable profits, the prices being proportioned to the distance to which they were conveyed. The war of independence, which has so greatly desolated the northern provinces of the Rio de la Plata, and the diminished working of the mines of Bolivia, have almost annihilated this lucrative traffic; but it may be expected to revive with increasing vigour on their again resuming their former habits of tranquillity, and becoming stimulated to increased exertion, by the accession of laborious and intelligent Europeans, and by the spread of education and intelligence.

By the route of Cordova, Tucuman, and Salta, the provinces of Upper Peru or Bolivia formerly received their supplies of articles of commerce from Europe, which were landed at Buenos Ayres; and by the same channel they likewise obtained large supplies of *Yerba* or Paraguay tea, to the great amount, it is affirmed, of 100,000 *arrobas*, or about 2,500,000 pounds annually, which had been previously conveyed by water from Paraguay to Buenos Ayres, and from thence by waggons and mules to Jujuy and Bolivia; thus enhancing its value by a circuitous and expensive land-carriage of from 2000 to 3000 miles, while by a more improved system of conveyance it might be sent by the rivers Vermejo and Pilcomayo into the heart of Bolivia, at a vast saving of trouble and expense. The large amount of goods sent from Buenos Ayres by waggons to Jujuy tended greatly to enrich the various provinces through which they passed, giving employment to numbers of the inhabitants; and Jujuy, which formed the most distant point that could be reached by waggons or carriages, became a place of considerable importance, forming the entrepôt of the commerce of Peru and the Argentine provinces. From this place the various articles of commerce were conveyed on mules to their ulterior destination.

The new order of affairs consequent on the revolution has necessarily produced important changes in this branch of commerce, and Bolivia has in a great measure ceased to receive her supplies of foreign commodities by this expensive route. Commerce, where unrestricted, always finds out the shortest and least expensive channels for the introduction of its commodities. The trade is now in a great degree diverted to the ports of the Pacific, called the Puertos Intermedios. Tacna and Arequipa, with their respective ports, have now become the principal channels through which Bolivia receives the produce and manufactures of other countries. How far the Bolivian government has succeeded in making Cobija or Puerto la Mar of that exclusive commercial importance which it contemplated, remains yet to be ascertained. Nature presents great obstacles to the success of the undertaking, which is certainly a most praiseworthy one; while Bolivia. all the rest of the coast, in which are situated the Puertos Intermedios, forms part of the republic of Peru, to which, therefore, they must necessarily pay transit duties. A new and very important channel of communication for commerce will be opened between Bolivia and the Atlantic, whenever commercial enterprise and increasing civilization shall have established steam navigation on the Rio de la Plata and its tributary streams, the Vermejo and Pilcomayo, and from the mouth of the Amazons to its distant tributaries the Beni and the Mamori.

By a decree of the republican government of Peru, dated 22d February 1831, the following judicious regulations have been established for settling the commercial relations of that state with the republic of Bolivia:—1. The productions of the territory of the Bolivian republic, introduced into Peru for its consumption, shall be subject to an import duty of four per cent. on their valuation. 2. Those productions of Bolivia which only pass through the territory of Peru for embarkation from its ports, shall only be subjected to a transit duty of two per cent. 3. Silver and gold, either coined or otherwise, introduced from Bolivia into Peru, shall be exempted from any duties. 4. All foreign articles of commerce passing through the territory of Peru, and destined for Bolivia, shall only be subjected to the payment of two per cent. *ad valorem*; and the decree of 22d January 1830, which imposed transit duties of from fifteen to forty-five per cent. on such commodities, has been repealed. 5. All articles of foreign commerce which are exempted from the payment of duties on their introduction into Peru, such as books, quicksilver, iron, machinery, &c., shall likewise be exempted from the payment of any transit duties on passing into Bolivia; and the decree of 5th March 1830, imposing a transit duty on such articles of fifteen per cent. has been repealed.

Population. The population of Bolivia has been variously estimated. By some authorities it has been computed at little more than half a million; by others, Berghaus in the number, at considerably more than two millions. No means existed, however, by which even an approximate correctness could be attained until in the year 1845 the existing government determined to take the census. It was then ascertained that Chuquisaca or Sucre, the capital and seat of government, contained only 20,000; Cinti, 15,000; the city of La Paz, 57,000; Lorata, 12,000; and Cochabamba, 30,000. In the western districts of the republic the towns and cities are even more thinly peopled. Atacama contains 1000 inhabitants; and Cobija or Puerto la Mar, the only seaport of the state, despite the efforts of the government to attract to it all the foreign commerce of Bolivia, has a resident population of only 500 souls. The exports of copper and the guano trade have of late years elicited some symptoms of vitality in these desolate regions, and Cobija is one of the few towns in the Bolivian republic whose population exhibits a tendency to increase. Its prosperity, however, is in the meantime seriously retarded by the proximity of Arica, a seaport of Peru, situated much nearer the productive districts of Bolivia, and in a region infinitely more fertile than that which surrounds Cobija. In 1562 a royal mint was established in Potosi, and the population of that city, formerly insignificant, increased with such rapidity that in the year 1611 it amounted to more than 160,000. At the end of the seventeenth century, however, the silver-mines in the neighbourhood ceased to yield the enormous returns which had once attracted adventurers from every quarter of the earth, and from that date the population of Potosi gradually declined. When the census was taken by govern-

Bolivia.

ment in the year 1845, it was found to amount to no more than 42,000.

The subjoined tables are compiled from the statistical returns made to the Bolivian government in the year 1845. It has been deemed advisable to append the names of the provinces, and the numbers of the cantons into which the departments have been respectively divided.

Department of Charcas La Plata, or Chuquisaca, now called Sucre.

Provinces.	No. of Cantons.	Population.
Chuquisaca	4	110,000
Cinti	9

The sum-total of the population of Bolivia according to these returns is 1,510,406. The literal accuracy of this estimate, however, is hardly to be depended upon, as the condition of the country has until recently been such as to afford few facilities for the correct investigation of many important points in its social economy.

Indians.

The civilized Indians inhabiting Bolivia, and descendants of the Peruvians under the empire of the Incas, are still numerous, notwithstanding the many causes which have so much tended to diminish their numbers, and form a distinct and peculiar race, preserving the language, the manners, and even the dress of their ancestors; their habits having been only somewhat modified by the peculiar circumstances and situation in which they have been placed since they came under the dominion of the Spaniards. They are naturally mild and passive, and seemingly a subdued and apathetic race; but these qualities are the natural result of that state of subjection and debasement in which they have so long been held by their merciless conquerors; and, under every disadvantage, they still possess a latent energy, which was fearfully exemplified in the insurrection under Tupac Amaru, during which great numbers of them perished, the victims of their patriotism. Their defects originate from extraneous causes; their virtues are their own; and, with the exception already mentioned, they are generally unstained by those great moral crimes which prevail in more civilized countries, and require the strong arm of the law to repress them. The plaintive ditties, or *yaravis*, in their sweet and melancholy tones, evince the prevailing feelings which animate them, and are highly characteristic of the race. They possess considerable intellectual talents and capabilities, and are exceedingly sensible of kindness and justice; to which, however, they have long been strangers. Any attempt at dictation, or an imperious behaviour, on the part of their superiors or strangers, always produces an opposite effect to that desired, and they become stubborn and reserved; but when treated with mildness, they usually relax from their accustomed apathy, and often evince to strangers, when in sickness or distress, proofs of the most genuine humanity and hospitality. This was experienced, in a remarkable manner, by General Miller, during his administration of the department of Potosi, where, by his just and benevolent demeanour towards them, he so completely won their confidence and good-will, that his name is still a sufficient passport with the whole nation. With their great numbers, the union of purpose they still exhibit, and the energy of which they are capable, it will require much tact and discernment on the part of the new republican government to prevent their eventually obtaining a powerful, perhaps injurious, ascendency in the country. By the judicious and excellent regulations established by the distinguished individuals into whose hands the charge of first organising the Bolivian administration devolved, all those odious and oppressive distinctions which had so long depressed the native energies of the Peruvian Indians have been for ever abolished, and in point of legal rights they have been placed on the most perfect equality with the other portions of the community. But new laws are often very inefficient when opposed by long-continued customs and inveterate prejudices; and the Indians of Bolivia are still in too many instances subjected to acts of oppression and injustice on the part of their more fortunate fellow-citizens. These occurrences, however, may be expected to diminish in frequency and extent, as education prevails and intelligence extends its beneficial influence over the country.

The Bolivian Indians are very industrious. The men attend their flocks and herds, and cultivate the land according to their rude and primitive modes of husbandry; while the women are usually employed in spinning, knitting, and weaving coarse fabrics, in the laborious occupation of pounding maize in a rude mortar, and in other domestic occupations. They live principally on vegetable food, especially maize and potatoes; but indulge freely in their favourite *chicha*, an intoxicating liquor, which they prepare from maize. They are apparently contented and happy, mild and submissive in their manners, and particularly amenable to those placed in authority over them, especially when *caciques* of their own nation, who in fact commonly hold the situation of *alcalde* in the Indian villages, and carry a gold-headed cane as their badge of office. By appealing to the people through these *alcaldes*, travellers will generally have their wants supplied in a manner which, under different circumstances, money could not provide for them. The Indians are very superstitious, and scrupulously devout in the performance of their religious duties.

They are generally of small stature, and resemble Malays in their physiognomy. They are robust and muscular, and are capable of undergoing great fatigue when travelling

Bolivia. on foot. Thus the postilions who usually accompany persons travelling on mules are frequently in advance, although they proceed on foot; and they perform long and toilsome pedestrian journeys of from twenty to thirty leagues a-day, with scarcely any other sustenance than a portion of the leaves of the *coca* plant, which they masticate in combination with the *llipta*, an alkaline substance prepared for the express purpose, and with a little roasted maize. From this custom of habitually travelling on foot, they are equal to undertakings which no other persons in South America can accomplish. They travel at a trot, take short steps, and keep their feet close to the ground. To this cause may in a great measure be ascribed the circumstance of the Spaniards having been able, during so long a period, to maintain their political superiority in the mountainous parts of Peru, and the success which usually attended their military operations in that country. Their infantry force being principally composed of native Indians, compelled to serve as soldiers, they were thus enabled to move with that decisive celerity which characterized most of their evolutions during the war of independence. As striking instances of this fact may be cited the feats of General Valdez and others previous to the dispersion of the patriot army of General Santa Cruz in 1823. Valdez, with his division of infantry, marched during fifty-seven successive days at the rate of seven leagues a day; at another time the royalist army marched eight leagues a-day for eight consecutive days; and on one occasion, previous to coming into action, they had actually accomplished a march of thirty-nine leagues, or 117 miles, in three days.

In all parts of South America, even in the most distant parts of Chili, the Argentine provinces, Colombia, and Brazil, may occasionally be met with, parties or groups of certain tribes of Peruvian Indians, who are denominated Callavayas. They always travel on foot, and carry on an extensive traffic in a variety of gums, resins, barks, and other medicinal productions, collected in the Yungas and other parts of the mountains, which are plentifully covered with vegetation, and in other parts of the provinces of La Paz and Larecaja, near which they principally reside. They also carry on an extensive and profitable practice as itinerant physicians, employing only their native remedies. They always travel along the remains of the ancient Peruvian roads, where such exist, these being uniformly the most direct; and they generally return to their own districts, sometimes after an absence of several years. They are very loquacious, and employ considerable artifice in extolling the virtues of their remedies and the extent of their own skill. Besides the Spanish language, which is that in general use in Bolivia, they employ the Quichua or language of the Incas; but the Aimaru is the language in common use in the department of La Paz.

Religion. Religion, as it has been practised in Bolivia and most other parts of South America, has long been in a very degraded state, consisting almost entirely in the repetition of a certain number of prayers, imperfectly understood by the greater part of the people, and the performance of a number of ceremonies, the object of which seems to be, to occupy the attention, and to serve as a pretext for extorting money from the community. It truly exhibited the form of sanctity without the substance; for the spirit of true religion was entirely lost sight of, and the higher faculties of reason and reflection were never called into exercise. With some few honourable exceptions, the clergy were profoundly ignorant of every thing appertaining to their sacred profession, and were only adepts in deception and immorality. They were notoriously licentious in their conduct, and although bound by their vow of celibacy to a life of chastity and virtue, they were the great promoters of vice and immorality, especially amongst the weaker sex, from the opportunities they enjoyed at the confessional, and the influence they possessed in virtue of the sacredness of their office. In South America, particularly in Bolivia and Peru, it has been quite customary for many of the curates to live in a state of concubinage with females, by whom they have numerous illegitimate children, who are generally designated as cousins, nephews, nieces, and the like, although every one is fully aware of the nature of the connection subsisting betwixt them. Bolivia.

The evil consequences resulting from this condition of the ministers of religion may easily be conceived. They fell as heavily upon the Creoles or Spanish South Americans as upon the Peruvian Indians; but the extortions which, under the semblance of religion, were exercised upon the ignorant, indigent, and inoffensive aborigines, almost exceed belief. Not contented with the salaries allowed them by the Spanish government, they weekly exacted contributions in various forms from the Indians on the administration of the communion and the other ordinances of religion, such as baptisms, marriages, and funerals; and the amount of these was graduated according to the discretion of the curate, and the knowledge he possessed of the ability of the devotee to defray them. By these, and other devices still more nefarious, the clergy generally contrived to amass large incomes, frequently seven or eight times the amount to which they were legally entitled; and many of the curacies in Peru thus afforded incomes of from 5000 to 15,000 dollars per annum.

Under the guidance of such spiritual leaders, and breathing a moral atmosphere so tainted, it could hardly be expected that pure and undefiled religion and morality could prosper and advance. The elements requisite to produce such effects were awanting, since neither precept nor example was given to the people; and it is rather matter of surprise that, in countries thus circumstanced, so many remarkable instances should be met with of individuals distinguished by a virtuous and amiable deportment. Such occurrences, however, speak volumes in favour of the naturally good disposition which characterizes them, and warrant the most pleasing anticipations of their future improved condition, when in the full enjoyment of the facilities and advantages presented by the extension of education and the diffusion of knowledge.

Free and unrestricted religious toleration does not yet exist in any part of South America, excepting in Buenos Ayres and Bolivia. Still, the bad consequences which have in some instances resulted from premature attempts to establish toleration in South America, where the public mind was not prepared for the reception of such a measure, induce us to deprecate the repetition of such attempts as exceedingly dangerous and injudicious, until some preparation has been made. At the same time, it would be an act of great injustice not to mention, that before and since the commencement of the revolution, there have appeared amongst the catholic clergy of South America, men whose just and benevolent demeanour, and whose enlightened patriotism and devotion to the cause of humanity, would do honour to any age or country. And of late years, when circumstances more fully favoured the development of the nobler faculties, many of them have taken a prominent part in promoting education, intelligence, and every institution calculated to improve the religious, moral, and intellectual condition of their countrymen.

Education. Since the commencement of the republican government, a considerable part of the revenues of the minor convents and monastic establishments in Bolivia has been diverted from their original purposes, to form a fund for the establishment and support of seminaries of education. Colleges on improved modern principles are forming in each of the departments, and Lancasterian schools are in course

Bolivia.

of being established in all parts of the republic. A university having long existed at Chuquisaca for the education of the youth of Upper Peru, the utility of the establishment was greatly augmented, during the administration of General Sucre, by an improvement in the modes of instruction, and an increase in the number of the departments of education, analogous to the advanced state of knowledge in other parts of the world. In Potosi, likewise, efficient means were adopted by General Miller, while prefect of that department, to establish there a college for the study of mineralogy; a branch of education of great importance in a place wholly dependent on mining.

Society.

The society in Bolivia is exceedingly agreeable, the inhabitants being kind, hospitable, and courteous to strangers. The ladies are particularly affable and pleasing in their manners, exhibiting a happy mixture between the reserve of the English and the vivacity of the French. Their countenances are handsome, they have small feet and ancles, and possess fine figures, with a most graceful carriage, especially in promenading, and when walking abroad. They dress with much taste, using at the church, and on occasions of ceremony, their former costume of the *basquina* and *mantilla;* but on other occasions they assume the more modern fashions of Europe. The fan, which they use with much dexterity, is a constant accompaniment on all such occasions. They have frequent *tertulias* or evening parties and balls, and dance with considerable gracefulness. Their conversation is agreeable, and even superior to what might be expected in a country which has enjoyed so little of the advantages of education and moral training.

History.

The early history of that part of the empire of the Incas which now forms the republic of Bolivia is so intimately connected with that of Peru, that the consideration of it may with propriety be deferred until we come to treat of that country, in which Cuzco, the capital of the Incas, is situated. Attention will therefore at present be directed only to that period of its history which is more recent, and which has so materially influenced its present condition,—the unsuccessful insurrection of the Peruvians or aboriginal population under Tupac Amaru, and subsequently the more fortunate war of independence. But before proceeding to the consideration of these, it seems requisite to point out the principal causes which gave rise to events so memorable in South American history.

Political state of the Indians.

The Peruvians, ever since the conquest of their country by the Spaniards in the sixteenth century, have been subjected to a system of tyranny and oppression which has few parallels in the history of the universe. They were treated little better than beasts of burthen. By their toil the gold and silver were obtained from the mines, the lands were cultivated, the flocks and herds were attended to, and all the domestic and menial offices performed. Yet the fruits of their labour, especially that of mining, which was attended with numerous privations, and too often with great loss of life, were altogether devoted to enriching their cruel oppressors. While so employed they were denied all the comforts and many of the necessaries of life; they were treated as minors, and considered as incapable of attending to their own affairs and interests, nay even deprived of the means of information and improvement; while the clergy powerfully contributed to the general degradation, by keeping them in the most profound ignorance of their moral and religious duties, and substituting instead of these a few unmeaning and useless ceremonies, by means of which they plundered the Indians, without ceremony or remorse, of the scanty pittance which they were able to save from the rapacity of their civil rulers. These heart-rending occurrences are fully detailed in the secret report of Don Jorge Juan and Don Antonio de Ulloa; which important document, after the lapse of nearly a century, was procured from the archives of Madrid, by our countryman Barry, and by him given to the public.

Bolivia.

One of their principal grievances was the *mita*, a compulsory kind of personal labour either in the working of the mines or in the cultivation of the fields, exacted from the Indians generally for the space of one year. The proprietors of mines and land to be worked or cultivated, were privileged to claim as their undoubted right, the personal services of the Indian population of the district surrounding that in which their property was situated. By the regulations of the *mita* a proportional number of the Indians of the district were annually chosen by lot for the purposes required; and some idea may be formed of the effects of such a regulation, by stating, that 1400 mines were registered in Peru alone, and that every mine which remained unworked a year and a day became the property of the first claimant.

So much was the labour of the mines dreaded by those persons on whom the lot fell, that they considered it as equivalent to a sentence of death, and made all their arrangements accordingly, carrying with them their wives and families to their new and dreaded place of abode. While thus employed, each person was nominally paid an allowance of four rials or two shillings daily, out of which he had to provide himself and family with food, clothing, and habitation, which were furnished to him at an exorbitant rate: the one third was retained for the purpose of paying the expense of returning his wife and family to their homes in the event of his death or at the expiry of his period of service; and besides, at the end of every year a tribute of eight dollars was exacted, which being in arrear, or any other debt contracted with his employer, was too often used as a pretext for retaining him in this odious service, generally till death put a period to his misery. An estimate may be formed of the extent of this evil, by stating that 12,000 Indians were annually required by the *mita* of Potosi alone; and it is calculated that, in the mines of Peru, no less than 8,285,000 Indians have perished in this manner.

Besides the *mita* for the service of the mines, the Indians were also compelled to labour for their superiors on their cultivated estates, their *estancias* or grazing farms, and also in their *obrages* or manufactories. In these latter establishments, according to Ulloa, they were obliged to work all day, and only received a pittance for their labour; the half of which was in many instances stopped to pay their arrears of tribute, and the other half was generally insufficient to pay for their necessary sustenance. The Indians were besides liable to serve as *pongos* or menial servants to the governors, and other functionaries, as likewise to the caciques and the curates; but for this service they received no recompense, excepting their food and clothing. The numbers employed in these domestic occupations in Peru and Bolivia have been estimated at 60,000.

The tribute exacted by the government from every Indian between the age of eighteen and fifty-five was a capitation tax of eight dollars. This was levied with the greatest rigour, and the official persons charged with its collection too frequently committed great injustice in doing so; obliging the Indians to commence these payments at fifteen, and continue them until seventy years of age, and putting the amount of tribute for the years before and after the legal period into their own pockets. In proof of the extent to which this evil was carried, and of the rapacity of the Spanish government, it may be stated that a law was enacted for the express purpose of augmenting the number of the people liable to pay tribute. By it the Indians were obliged to marry, the men at the age of fifteen, the women at thirteen. The governor of each province was responsible to the government for the amount of the tribute, which was regulated by a census of the tributary Indians,

taken every seven years; and in this many frauds were practised, the actual number being often much underrated. The governor of the province of Porco, in the department of Potosi, according to the testimony of Miller, was believed to have collected annually a surplus of 10,000 dollars by these fraudulent means. This tribute continued to be exacted until the year 1825, when it was finally abolished by General Bolivar on his arrival in the country; and all the Indians now enjoy the same rights and privileges as the other inhabitants of the country.

Besides all these, the Peruvian Indians were long subjected to another system of extortion no less grievous and unjust,—the law of *repartamiento*. This was originally established with the best intentions; the governors or *corregidors* of the districts being intrusted with the charge of supplying the inhabitants under their care with such articles as they might require at a fair and equitable price. But the law, which had so plausible an origin, was shamefully abused; and it was made compulsory on the Indian population to purchase articles of the most worthless description, both in kind and quality, whether they required them or not, and at a price double or treble that for which the same article of the best possible quality might have been purchased. Thus razors were forced at an exorbitant price on Indians who had no beards to shave; and those who had never gone otherwise than barefooted were compelled to purchase velvets and silk stockings, of the use of which they were even ignorant. On one occasion a large assortment of spectacles was forwarded to a merchant at Lima, who, finding them unsaleable in a country where the natives proverbially retain their vision unimpaired till an advanced period of life, got them disposed of at an exorbitant profit by consigning them to a *corregidor*, who issued a decree to the Indians of his district, ordaining that no Indian should be permitted to attend divine service on certain occasions without having on a pair of spectacles. A *repartamiento* took place in 1743, at about forty leagues from Lima, where the *corregidor* exacted the sum of 300,000 dollars for goods which he had purchased at 70,000 dollars. The Indians of this district, according to Ulloa, "finding themselves tyrannized over with greater cruelty than they had experienced from the predecessors of the *corregidor*, determined to complain to the viceroy, and produced before him the goods, together with the proofs of the exorbitant prices which they had been obliged to pay for them. We do not state this fact from report, as we happened to be present when the Indians came to make known their grievances. The viceroy heard them, and referred them to the *audiencia;* and the result was that the Indians were seized and punished as insurgents."

These accumulated grievances at length exceeded even the powers of endurance possessed by these pacific Indians, and gave rise to the memorable insurrection of Tupac Amaru in 1780, in which torrents of native as well as Spanish blood were shed before it was finally suppressed. This event, however, gave a death-blow to the law of *repartamiento*, which was then finally abolished.

Political state of the Creoles.

The constant and extensive operation of these demoralizing practices, although more immediately affecting the aboriginal population, could not fail to produce the most pernicious and injurious effects on the Creoles or descendants of the Spaniards; but, in addition to these causes of debasement, the latter were subjected to numerous unjust and oppressive laws, all tending to paralyze their advancement in industry, intelligence, and civilization.

The raising of those vegetable productions which form the principal objects of culture in Spain, as articles of commerce, was strictly prohibited to the South Americans, however favourable the soil and climate of their native country might be for the production of them. The prosperity and happiness of the transatlantic population were of no value or importance when put in competition with the interested views and wishes of the mother country. Thus the cultivation of the vine and the olive was either prohibited, or the plants were rooted out where they had been introduced. Prohibitory decrees were issued against the manufacture of wines, brandies, vinegar, olive oil, &c.; and even the culture of almonds and raisins was interdicted. No kind of manufacture of cloth or articles of clothing was permitted which could interfere with the commerce of Old Spain, excepting only the coarse fabrics manufactured and worn by the Indians. Even the valuable mines of mercury and iron found in South America were, in a great measure, hermetically sealed by prohibitory decrees, lest they might interfere with the traffic carried on by Spain in these articles. And, not contented with confining the commerce of South America entirely to Spain, and prohibiting it under the severest penalties with other nations, these colonies were not permitted to have any intercourse or commerce with each other.

The South Americans were generally excluded from all offices of honour or emolument in their own country; and when any deviation from this law took place, it was too frequently in consequence of enormous bribes received, or a reward to some unnatural Creole for acts of cruelty and oppression committed on his own countrymen. They were also systematically deprived of the means of obtaining a suitable education for their children; nothing being taught at their seminaries excepting Latin, philosophy, the civil and canon law, and theology, while every attempt at improvement on the part of the natives was resisted by the government.

Insurrection of Tupac Amaru.

The upper provinces of Bolivia and Peru were those which formed the principal scenes of the memorable insurrection of Tupac Amaru, so just in its origin, so energetic in its prosecution, and so unfortunate in its results to the Peruvian nation. From the details which have appeared of this eventful period, it is evident that a deep-rooted feeling of the oppressive and degrading servitude to which they had so long been subjected by the Spaniards, united with a lively recollection of the happiness and glory of their more fortunate ancestors, conspired to rouse the latent energies of the whole nation to accomplish their liberation from the cruel yoke under which they had groaned. And they found an able and a willing leader in Jose Gabriel Condorcanqui, cacique of Tungasuya, a lineal descendant of the Inca Tupac Amaru, whose name and title he afterwards assumed. But although an excellent and intrepid man, and possessing the entire confidence of his countrymen, he was deficient in that knowledge, foresight, and energy, so requisite for conducting to a happy termination so difficult and hazardous an enterprise. He experienced various successes and reverses, but was eventually taken prisoner, and put to death in the most barbarous manner by the Spaniards. He was succeeded in the direction of the enterprise by his nephew Andres, who, with the aid of Catari and other caciques, continued the contest with great and indiscriminate carnage on both sides; but having to contend against the superior skill, discipline, and arms of the Spaniards, aided by treachery, they were finally overcome, and the insurrection was put down in 1782.

Having thus failed in their arduous undertaking, after the destruction of great numbers of their nation—for neither the lives of men, women, nor children, were spared on either side during this sanguinary contest—their chains were rivetted with double force; and the sorrow and despondency which followed these disastrous events were so great that they never again recovered their wonted energies. Yet there is every reason to believe that, had they possessed better arms and discipline, more knowledge and

Bolivia.

experience, and leaders better adapted for such an enterprise, they would, from their number, union, and devotion to the cause, have finally accomplished their deliverance.

These circumstances will account in a great measure for the apathy and comparative indifference with which they viewed the rise and progress of the war of independence, the objects of which they did not rightly understand, and found difficult to reconcile with their knowledge of the active part taken by the Creoles in the suppression of their own previous endeavours to throw off the Spanish yoke.

War of independence.

From the causes already stated, the war of independence was principally carried on, as regards Bolivia, by the resources of, and in concert with, the neighbouring provinces of the Rio de la Plata and Peru, all of which had equal cause to avenge themselves on their oppressors, but were placed in circumstances somewhat more fortunate for accomplishing their purpose. When the patriots of Buenos Ayres had succeeded in liberating, from the dominion of Spain, the interior provinces of the Rio de la Plata, they turned their arms against their enemies in possession of Upper Peru. General Antonio Balcarce was therefore sent with the forces of Buenos Ayres into that country, and succeeded in defeating the royalist general Nieto, at Cotagaita, on the 27th October 1810; and on the 7th November following, a similar fate overtook Colonel Cordova at Tupiza. These successes gave him possession of the country as far as the bridge of the Incas, which crosses the river Desaguadero; at which time his army had been increased by recruits to about 4000 men. Castelli was sent from Buenos Ayres as governor of Upper Peru, and to act as the commissioner of the Argentine government, with the army of Balcarce. He was a man distinguished for his great and versatile talents, but was of a restless and fiery temper. By the violence of his proceedings, and numerous acts of unjustifiable cruelty, he so far succeeded in inspiring the Spaniards with terror and dismay, that the army of Buenos Ayres was enabled, on the 25th of May 1811, to celebrate the first anniversary of their independence among the ruins of the palace of the Incas at Tiaguanaco, on the shores of the lake of Titicaca, 690 leagues distant from Buenos Ayres. The dissolute conduct of Castelli, however, and the irregularities of the Buenos-Ayreans who accompanied him, tended greatly to alienate the affections of the inhabitants of Upper Peru from their deliverers, and considerably aided the efforts of Abascal, viceroy of Peru, who, after some unsuccessful attempts to conclude an armistice with Castelli, in which little courtesy seems to have been observed on either side, collected all his disposable forces under his best generals. The civil administration of the provinces was neglected by the patriots; and the army became disorganized, from the dissolute conduct and negligence of Castelli and his followers. General Goyeneche was intrusted with the command of the Spanish army, which, to the amount of 4000 men, took up a position on the north side of the Desaguadero, two days' march from their opponents. In the interim an armistice had been concluded between the two contending armies; but, regardless of the inviolability of such a transaction, Goyeneche attacked and defeated the patriot army under Balcarce and Castelli at Huaqui, on the 20th June 1811, six days before the expiry of the truce. Balcarce retired from Bolivia with the remains of his army, and took up a position at Jujuy, distant 236 leagues from the scene of action. After his success Goyeneche committed great cruelties in Bolivia, particularly at Chuquisaca and La Paz; but he met with considerable opposition from the patriots, who had retired to the mountains of Cochabamba, Santa Cruz de la Sierra, and Chayanta.

General Belgrano, who succeeded to the command of the army of Balcarce, had the good fortune, at Tucuman, to defeat the royalist army, 3000 strong, under General Pio Tristan, on the 30th September 1812, while his own force did not amount to half that number. And, again, on the 20th February following, he obtained another victory over the same general, who had entrenched himself in Salta with 2000 men, all of whom were either killed or taken prisoners. Belgrano generously permitted the vanquished Tristan, with his officers and men, to return to Peru, on their giving solemn pledges not again to bear arms against the republic of the Rio de la Plata. But all of them, influenced by the example of their general, and regardless of their obligation, violated their parole, and joined the army of Pezuela, which, by such dishonourable means, was augmented to 4000 men. With these he attacked Belgrano, who, with his army, had advanced into Upper Peru, and defeated him at Vilcapugio, between Oruro and Potosi, on 1st October 1813; and again at Ayoma, in the department of Cochabamba, on the 14th November of same year. Belgrano escaped with the remains of his army to Tucuman.

Bolivia.

Notwithstanding these disasters, the cause of independence did not slumber in Upper Peru, since numerous bands of patriots maintained themselves in Cochabamba, Santa Cruz de la Sierra, Chayanta, and Yamparaes, and obtained many advantages over the royalists, under the able command of Warnes, Camargo, and Padilla, who carried on a guerilla warfare. On 25th May 1814, Colonel Arenales obtained some advantages over his opponents in the provinces of Cochabamba, and Warnes was equally fortunate on the 9th October following, in the Quebrada of Santa Barbara. Guemes, with the irregular troops of the province of Salta, cut off the supplies of the royalists in front; whilst the guerilla parties under Warnes, Padilla, and Muñecas, in the rear, so distressed them, that Pezuela with his army was obliged to retire upon Cotagaita. The patriot army at Tucuman under the command of General San Martin never came into collision with the royalists until after his removal to the command of Cuyo, when General Rondeau succeeded him in the direction of that army, amounting to 3500. With these he marched again into Upper Peru against the royalists, whom, in nearly equal numbers under Pezuela, he encountered at Sipe-sipe, between Potosi and Oruro, on 28th November 1815, and was totally defeated; and this was followed soon after by another defeat at Viluma, which again placed Upper Peru under the control of the royalists. General Belgrano was a second time appointed to command the army stationed at Tucuman, composed of the remains of the army which had been vanquished at Sipe-sipe and Viluma; and, by unwearied exertions, he soon collected a force of about 4000, well equipped. But a spirit of disaffection and anarchy had crept into his army, which, incited by the principal officers, revolted against their general. He was deposed and made prisoner; and the officers, with such soldiers as chose to follow them, dispersed over the provinces, where, in many instances, they usurped the civil and military administration, which in some cases they retained until a late period.

To these events succeeded, under Pumacagua, an insurrection of the Indians of the neighbouring provinces of Arequipa, Cuzco, and Huamanga, in Peru; and the object being the independence of the whole country, it was joined by numerous Creoles from Bolivia and Peru. But this attempt was speedily put down by the activity of the royalist general, Ramirez, who inflicted a severe retaliation on Pumacagua and his followers. After this period Upper Peru remained tranquil for a considerable time, unless when disturbed by the enterprises of Lanza and his followers, who maintained themselves in the Yungas.

On the viceroy Abascal being superseded in that office

Bolivia. by Pezuela, General Laserna was appointed commander in chief in Upper Peru, where he arrived in September 1816, with 2000 fresh troops. He introduced many innovations, and very humanely prohibited the infliction of the punishment of death for political offences, without his previous permission. He made an attempt, with an army of from 4000 to 5000 men, to penetrate into the Argentine provinces, intending to march to Buenos Ayres; but he was completely foiled by the activity and intrepidity of the *Gauchos*, or irregular troops of the provinces of Salta and Jujuy, and was compelled to retire with the remainder of his army to Cotagaita.

The expedition of General Santa Cruz, prepared with great zeal and activity at Lima, landed in June 1823, in the Puertos Intermedios, and marched in two divisions to Upper Peru: the one under Santa Cruz by the Cordillera of Iscuchaca, obtained possession of the bridge of the Incas on the Desaguadero on 29th July, and occupied La Paz on the 7th August; the other division, under General Gamarra, marched by the route of Tacora and San Andres de Machaca, and reached Calamarca on the 10th August, where it had a sharp rencontre with a division of the army of General Olañeta, and then marched to Oruro, where it was joined by Lanza with 600 men. During six years the latter had maintained himself in the Yungas with great valour against all the efforts of the Spaniards. At this period General Urdininea, with 1000 men, occupied the quebrada or defile of Humaguaca, near Jujuy, ready to approach Potosi on the first favourable occasion.

At this time the royalist force in Upper Peru, under Olañeta, did not exceed from 2000 to 3000 men, besides about 1500 men in garrison at Puno and La Paz. But Canterac, then near Lima, hearing of the large army which had gone to Upper Peru under Santa Cruz, dispatched General Valdez with three batallions of infantry, 400 cavalry, and two cannon, to unite with the forces under the viceroy Laserna, and Generals Carratala and Olañeta. On the other hand, General Sucre also sent from Lima 3000 troops, either to co-operate with Santa Cruz, or to act separately, as occasion might require; and he soon afterwards proceeded in person to command them, with authority from the congress, if necessary, to assume also the command of the army under Santa Cruz.

Santa Cruz remained in quiet possession of Upper Peru, occupying the country from Oruro to the bridge of the Incas, his head-quarters being at La Paz. Valdez proceeded by Andaguaylas and Sicuani towards Puno, having completed a march of about 400 leagues in fifty-seven successive days. On the approach of the royalists, Santa Cruz took up a position near the bridge of the Incas; and at Zepita, on the 25th August, fought an indecisive action with Valdez, who commanded 1800 men, his own force being only 1600. The royalists immediately concentrated their forces at Sicuani, amounting to 4500 men, whilst those of Santa Cruz were about 7000 men. Various movements now took place on both sides, which evinced much skill and activity on the part of the royalists, and great indecision and want of judgment on the part of Santa Cruz. The royalists being at length joined by the forces of Olañeta, amounting to 2500 men, and considering themselves equal in number to the patriots, began to act on the offensive, and came in contact with the army of Santa Cruz at Sicasica. But this general showed no disposition to come into collision with the royalists, and retreated towards Aya-aya, losing some of his baggage, and many deserters. He appears to have resisted all the endeavours and entreaties of his officers, as well as the declared wishes of his army, to rally and engage the enemy. A severe storm, which overtook them here, served to increase their disasters, and converted the retreat of the army into a precipitate flight. The fugitives retired by Santa Rosa and Moquegua towards Ilo, where about 1300 embarked in the transports; but of an army of 7000 men only 1000 returned to Lima. About 1000 retired from Sicasica with Lanza, but were afterwards defeated by Olañeta, and their leader and a few followers only escaped to the mountains. It is difficult to account for the strange infatuation which led to the destruction of this fine army, as Santa Cruz on other occasions had shown himself an able commander; but these events will always remain as a cloud upon his military character. Bolivia.

In May 1824, Generals Valdez and Olañeta occupied Upper Peru, each with about 5000 men under his command, but opposed to each other on political points; the former having withdrawn his allegiance from the viceroy Laserna, in consequence of advocating the constitutional cause of Spain, while Olañeta adhered to the principles of absolute monarchy. This dispute was useful to the cause of the patriots, as it prevented Olañeta from uniting his forces with the viceroy during the campaign which terminated in the battle of Ayacucho, so glorious to the cause of freedom. General Sucre, whose abilities and valour so much contributed to the success of that day, improved the advantages he had obtained, by his clemency and generosity to the vanquished, and by the rapidity with which he followed up his successes; so that none of the fugitives could unite with the army of Olañeta, now the only royalist general in arms in Upper or Lower Peru. A part of the army, therefore, proceeded towards Upper Peru, and in their march experienced in some instances great hardships; the division of General Cordova having lost many men near Santa Rosa, from *surumpi* or snow blindness.

On hearing of the victory of Ayacucho, the patriot prisoners of war confined in the island of Chuquito, in the lake of Titicaca, rose on their guards, whom they overcame; and placing themselves under the command of General Alvarado, likewise a prisoner, they took possession of the country as far as the bridge of the Incas; a division of 1500 patriots under the command of General Urdininea still occupying the quebrada of Humaguaca, on the southern frontier of the department of Potosi. General Olañeta, however, still retained his position in Upper Peru, at the head of about 4000 men, having refused to accede to the liberal and even generous terms of accommodation proposed to him by General Sucre. The latter, therefore, on recruiting his army after the fatigues they had undergone, and supplying them with clothing and other necessaries, advanced to Oruro, and afterwards to Puno, which he reached on the 1st February 1825, and there obtained information that the royalist garrisons of Cochabamba, Chuquisaca, and Santa Cruz de la Sierra, had declared for the patriots, and that the city of La Paz was in possession of the gallant and indefatigable Lanza. Olañeta, with his army, diminished to 2000, was confined to the department of Potosi, but still persisted in his determined opposition, notwithstanding the entreaties and remonstrances of Colonel Medina Celi, his second in command, who at length, with a considerable portion of his army, rose against him. Olañeta, with a few resolute followers, resisted to the last; until, in an action with some of his own revolted troops at Tumusla, sixteen leagues south of Potosi, he was mortally wounded, on the 30th of March 1825.

General Sucre was now invested with the supreme command in Upper Peru, until the requisite measures could be taken to establish in that country a regular and constitutional government. Deputies from the various provinces to the number of fifty-four were assembled at Chuquisaca, the capital, to decide upon the question proposed to them on the part of the government of the Argentine provinces, respecting their separation or otherwise from that country. In August 1825 they decided this question, and declared

Bolivia.

it to be the national will that Upper Peru should in future constitute a distinct and independent nation. This assembly continued their session, although the primary object of their meeting had thus been accomplished, and afterwards gave the name of Bolivia to the country; issuing at the same time a formal declaration of independence. They also voted one million of dollars to General Bolivar, as a reward for his past services; and an equal sum to those belonging to the army who had served in the campaign of 1824. The former grant, however, was only accepted by Bolivar on the express condition that it should be wholly appropriated to purchasing the freedom of about a thousand slaves still existing in Bolivia.

The first general assembly of deputies of Bolivia dissolved themselves on the 6th of October 1825, and a new congress was summoned, and formally installed, at Chuquisaca, on the 25th May 1826, to take into consideration the constitution prepared by Bolivar for the new republic. A favourable report was made to that body by a committee appointed to examine it, on which it was approved by the congress, and declared to be the constitution of the republic; and as such, it was sworn to by the people. General Sucre was chosen president for life, according to the constitution; but only accepted the appointment for the space of two years, and on the express condition that 2000 Colombian troops should be permitted to remain with him, which request was agreed to by the congress.

Bolivian code.

The Bolivian constitution is founded on the strictest principles of justice, in as far as regards the civil rights and privileges of the community; but in other respects, and particularly in reference to the supreme executive authority, its provisions savour strongly of a monarchical spirit. The supreme authority is vested in a *presidente vitalicio*, or president for life, with the power of naming his successor. It guarantees to the Bolivians civil liberty, security of persons and property, and equality of rights; the free exercise and communication of thoughts and opinions, either by the press or otherwise; liberty to remain or leave the territory of the republic with their property, at their pleasure, but without prejudice to others; equality in the imposition of taxes and contributions, from the payment of which none can be exempted; and the abolition of all hereditary employments, privileges, and entails. No profession, trade, or employment, can be prohibited, unless repugnant to public feeling, or injurious to the health and security of the community; and every inventor is secured in the benefits of his discovery. No one can be arrested without previous information of the alleged fact of delinquency, unless when taken in *flagranti delicto*. All trials and judgments are public; and in criminal cases none can be imprisoned more than forty-eight hours without having presented to him the charges preferred against him, and being delivered over to the proper tribunal or judge. No demand for redress in civil or criminal cases can be brought judicially before the justices of peace, until they have first endeavoured to promote reconciliation, by hearing the representations of the parties, explaining to them their respective rights, and proposing some means of accommodation.

By this constitution, all legitimate power emanates directly from the people, and is in the first instance exercised by all who can justly claim the privilege of citizens. Of these, every ten nominate an elector, who exercises his delegated authority for a period of four years. At the commencement of each year all the electors assemble in the capitals of their respective provinces, and regulate their proceedings and the exercise of their various functions by a plurality of votes. They elect the members of the three legislative chambers, the number for each amounting to thirty; those for the chamber of tribunes being nominated for four years, and renewed by moieties every two years; those for the senate for eight years, and renewed by moieties every four years; and those for the chamber of censors being nominated for life. The electors also exercise the privilege of proposing in ternaries, 1*st*, To the executive power, all candidates for the prefectures of departments, for the government of provinces, and for corregidors of cantons and towns, and also curates and vicars for the vacancies in their provinces; 2*dly*, To the senate, the members of the courts of the judicial district to which they belong, and the judges in the first instance; and, 3*dly*, To the prefect of the department, the alcaldes and justices of the peace, who are to be appointed in their respective provinces.

Bolivia.

The functions of the chamber of tribunes are, to originate all laws respecting the revenue, peace and war, and to exercise an immediate inspection of those branches which are administered by the executive, with the least intervention of the legislature. This chamber also possesses the initiative in the settlement of the territorial division of the republic; the coinage, weights and measures; the seaports, roads, bridges, and public buildings; the police, &c.

The attributes and functions of the chamber of senators are, to form the civil, criminal, and ecclesiastical regulations and codes, and watch over the tribunals of justice and religion; to choose, from the ternaries presented to them by the executive and by the electoral body, the prefects, governors, corregidors, judges of districts, and all others in the department of justice; to propose to the chamber of censors those who are to be members of the supreme tribunal of justice, the archbishops, the bishops, dignitaries of the church, canons, and prebends; and to examine the decision of ecclesiastical courts, bulls, rescripts, and pontifical briefs, with a view to their approval or disapproval.

The chamber of censors exercise a political and moral power. It is their duty to watch that the constitution, the laws, and treaties, are strictly adhered to and executed; and to express the national judgment, when such is rendered necessary by the good or bad administration of the executive government. The censors are also charged with the protection of morality, the arts and sciences, education, and the press. They exercise the important functions of condemning those who usurp sovereign power, or are guilty of high crimes and malversation; and they bestow public honours and rewards on the services and virtues of illustrious citizens. This chamber also exercises the functions of choosing, from the ternaries presented to them by the senate, those who are to form the supreme courts of justice, to become archbishops, bishops, canons, and prebends.

The general or collective duties and attributes of the three chambers, when united, are, to nominate the president of the republic for the first time, and to confirm his successor; to approve of the vice-president proposed by the president; to determine on the seat of government; to decide on any charge against members of the chambers, the vice-president, or secretaries of state; to invest the president with extraordinary powers in cases of great emergency or danger; to select from the candidates presented in ternaries by the electoral bodies, those members who are to fill up the vacancies of the chambers; and to regulate and judge the department of police. All the sessions must be public, excepting in such state cases as require secrecy. No public functionaries are capable of being members of the chambers; and the latter enjoy inviolability in their persons for opinions expressed, and are not subject to arrest.

The executive government consists of a president, vice-president, and three secretaries of state. The president of the republic is named for the first time by a majority of the collective legislature, and retains the dignity during life, with the power of naming his successor. He is the chief of the administration of the state, and is not

 responsible for the acts of his administration. On his death, resignation, or infirmity, the vice-president is virtually his successor. In the absence or non-existence of both of these functionaries, the three secretaries of state take charge, *ad interim*, of the administration of the government, the oldest in office acting as president until the assembling of the legislature. The constitutional privileges of the president are the most limited that have been intrusted to the supreme chief of any nation. They extend only to the nomination of the officers of the revenue, of peace and of war, and the command of the army. He proposes to the chambers the vice-president, and he nominates the three secretaries of state, and can remove any of these functionaries when he judges it necessary. He appoints all diplomatic functionaries; receives foreign ambassadors and agents; directs all negociations; and, with the previous sanction of the legislature, concludes treaties of peace, alliance, commerce, &c. He presents to the senate, for its sanction, one of the three candidates proposed by the electoral body for each of the situations of prefect, governor, and corregidor; and to the ecclesiastical government, one of the three candidates proposed by the electoral body for each of the offices of curate and vicar in the provinces. He authorizes the regulations for the proper fulfilment of the constitution, laws, and treaties; he forwards and causes to be executed the sentences of the tribunals; and he has the power of commuting capital punishments awarded by them.

The president cannot deprive any Bolivian of his liberty, or inflict punishment on him, of his own accord; nor can he imprison any one longer than forty-eight hours without delivering him over to the proper judge or tribunal; nor deprive any individual of his property, unless such a proceeding be urgently demanded by the public interests; nor impede the elections or any other public functions authorized by the laws; nor absent himself from the republic or the capital without permission of the legislature. He is nominated for life, and made irresponsible as a security for his permanency; but his hands are nevertheless tied, so that he cannot do injury to any one. He does not nominate the magistrates and the judges, nor does he appoint to any ecclesiastical dignity, however subordinate; and hence he is, at least nominally, deprived of the powerful influence over society which is exercised by other supreme rulers. The administration belongs wholly to the ministry, which is responsible to the senate, and is subject to the zealous vigilance of the legislators, magistrates, judges, and citizens.

The vice-president is proposed by the president, and approved of by the legislature. He is at the head of the ministry, and, with the secretaries of state, is responsible for all the acts of the administration; while, in the name of the president and the republic, he signs all the public documents, along with these secretaries, in order to legalize the orders of the executive. Of all the magistrates intrusted with command, the vice-president is that one whose hands are most shackled; for he has to obey both the executive and the legislature. He receives laws from the latter, and orders from the former; and between the two has often a difficult course to steer. His nomination as the successor of the president insures the services of an individual whose previous experience in the difficult art of government, and knowledge of those in subordinate situations, render him the most eligible of any for such an office; and by this means are avoided those elections for the supreme ruler so productive of mischief in other republics. As the expectant of the supreme command, the vice-president has the most powerful motives for the zealous and conscientious discharge of his functions, in order to secure, on the one hand, the confidence and support of the president, and, on the other, that of the legislature and the people. The three secretaries of state are for the home and foreign departments, for the finance, and for war and marine; and each is required to give in accounts of the expenses incurred in his respective department, and the estimates for each ensuing year.

The judicial power enjoys the most perfect independence, the members composing it being proposed by the people, and chosen by the legislature; a condition which insures the strict and impartial administration of the laws. Tortures and confessions are altogether abolished, as repugnant to humanity. The territory of the republic is governed by prefects, governors, corregidors, justices of the peace, and alcaldes; and the proportion of these is regulated by the population: the details to be defined by the congress; and every one in the enjoyment of office is made responsible for his actions. The armed force is composed of the regular army to garrison and defend the frontiers, of the national militia to preserve internal order, of the preventive service to protect the revenue, and of the navy, when circumstances may require the formation of such.

Slavery in every form was abolished, as inconsistent with the just rights of mankind, and at variance with the whole spirit of the constitution. The exercise of religion was freed from all restraints; it being considered incompetent to legislate in matters affecting the conciences of others.

Such are the principal features of the Bolivian constitution, the merits of which will be variously estimated, according to the particular political bias of each individual. It contains in theory much that seems calculated to insure the liberty, the prosperity, and the happiness of the community. The legislative portion has been objected to as being too complicated for practical purposes; but this requires to be put to the test of experience. No part of it, however, has excited more criticism, or given rise to more sinister suspicions, than that which provides for the election of a president or supreme ruler for life, with the power of nominating his successor. With such a provision, the Bolivian constitution is, in fact, nothing more nor less than a limited monarchy, somewhat incuriously disguised under republican forms. This seems undeniably its political character; and although it may have worked tolerably well in Bolivia, the country for which it was ostensibly intended, and where, according to the latest accounts, it still subsists, yet there seems to be little doubt that it was conceived in a spirit more friendly to individual aggrandizement than to the liberty of the people or the ultimate consolidation of republican institutions.

Had Bolivar, the lawgiver of this republic, ceased to exist, or had he retired altogether from public life, on the promulgation of the Bolivian code, his reputation as a patriot and a statesman would have been handed down to posterity as one of the brightest in the annals of history. But, unfortunately, the formation and establishment of this constitution gave rise to events in Peru, Colombia, and other parts of South America, which incontrovertibly prove that it was not dictated by that pure spirit of patriotism which his friends and admirers have attributed to Bolivar; but that under it lurked a gigantic scheme of ambition and aggrandizement, in fruitless endeavours to accomplish which much crime and misery were occasioned, whilst the glory which its author had previously earned contracted a stain which, it is to be feared, no length of time will ever efface. The project which emanated from the promulgation and establishment of this code in Bolivia, and in the prosecution of which Bolivar principally employed his active energies during the latter years of his life, was, the establishment of the same constitution in Peru and Colombia as well as in Bolivia, and the union of these three republics, either federally, or as one state, of which he was to be the president for life. The celebrated congress at Panama, which took place in June 1826, was originally pro-

Bolivia. jected by him for this express object; and many other expedients, which it is foreign to our present purpose to enumerate, were also resorted to for the accomplishment of his design. But all his schemes proved abortive, and he died without effecting any of the objects, personal to himself, for which he had compromised his fame, and incurred the suspicion and dread of all who were friendly to republican institutions.

The congress which sanctioned the adoption of the Bolivian code, and elected General Sucre as the president of the republic, continued its sessions, to legislate more in detail. The republic was peculiarly fortunate in its first choice of a president in the person of the conqueror of Ayacucho, whose mildness, urbanity, integrity, love of justice, and devotedness in the discharge of the important duties confided to him, endeared him to every one capable of being influenced by generous feelings. He had few personal enemies; and those who opposed him were principally influenced by the impression of his intimate connection with Bolivar, and of his favouring the political principles advocated by the latter; for all viewed Sucre as the firmest and most energetic supporter which Bolivar possessed. Under the upright administration of this officer much progress was made in organizing the various departments of the administration; the resources of the country were called forth; and effectual means were adopted for promoting the extension of education and intelligence throughout the community.

Amidst these powerful inducements to tranquillity, much discontent was excited by the presence of a body of Colombian troops in the country, which, in a period of profound peace, was considered by many as derogatory to the dignity, and inconsistent with the liberty, of the republic. The number influenced by such feelings was greatly augmented by the accession of those aspirants to place and power, who considered their respective claims as having been neglected or ill requited; and strength and consistency were given to these malcontents, by a belief, which subsequent events proved to be well founded, that the government of Peru favoured their views, and that they would be supported by a numerous and well-appointed Peruvian army, stationed in the department of Puno.

Meanwhile they succeeded in gaining over to their party the Colombian battalion of voltigeros stationed at La Paz, among whom a mutiny took place on the 23d December 1827; but this was speedily suppressed by the Colombian cavalry under Colonel Brown, and the armed peasantry of La Paz, after a desperate resistance on the part of the mutineers, of whom eighty were killed. The battalion was consequently disbanded. This revolt was hailed with loud demonstrations of joy by the government and people of Peru, who viewed it as the first step towards the downfall of the policy of Bolivar.

General Sucre, convinced that removing the principal source of discontent was essential to the stability of the constitution and the welfare of the country, applied to the government of Peru for permission to the Colombian troops to march through the territory of that state, and embark at Arica. But the Peruvian administration denied to these brave men the privilege of returning to their native country by the route by which they had formerly advanced to establish the freedom of Peru, unless they submitted to the humiliating condition of suffering themselves to be disarmed; a condition which was spurned at by Sucre and the Colombians. On the 5th March an interview took place near the Desaguadero, between Generals Sucre and Gamarra, the latter commanding the Peruvians. On this occasion each disclaimed any intention of interfering in the internal affairs of the republic to which the other belonged; a pledge which subsequent events proved to have been insincere on the part of Gamarra. General Sucre succeeded, however, in obtaining the sanction of Gamarra to the embarkation at Arica of all the Colombian troops in Bolivia, excepting about 500 men; and this was accordingly carried into effect without any further opposition on the part of the Peruvians. Bolivia.

While Sucre was occupied with these transactions, the spirit of discord had extended itself to Chuquisaca the capital, and spread amongst the garrison. With the view of repressing this disorder, Sucre rode in amongst the mutinous soldiers, accompanied by his staff and a few other officers; but he was unsuccessful in his attempt to quell the mutiny; Colonels Lanza and Escalona were mortally wounded, and the general himself was so severely wounded as to be made prisoner. This revolt, however, was ultimately suppressed by General Lopez with some troops from Potosi, aided by the well-disposed inhabitants of Chuquisaca; and Sucre was set at liberty. But he intimated his fixed determination not to resume the office of president, except for the purpose of resigning it into the hands of congress, at its first meeting.

On hearing of the affair at Chuquisaca, Gamarra called a council of war, the members of which, with only one dissentient voice, agreed as to the propriety of his marching into the Bolivian territory, with the ostensible object of preventing anarchy, and protecting Sucre from further personal violence; and this resolution was soon afterwards sanctioned by orders to the same effect from the Peruvian government. Accordingly, Gamarra and his army crossed the Desaguadero on the 1st of May; but they were coolly received by the Bolivians, whose forces being too few for resistance, retired from La Paz, and concentrated themselves towards Oruro and Potosi, under the command of General Urdininea. But the latter, instead of advancing with his whole forces to encounter Gamarra, weakened his army by detaching a large division, in order to reduce a mutinous regiment of cavalry under Colonel Blanco, in the province of Chichas. Ineffectual endeavours at negociation were followed by some indecisive affairs between the two armies in the province of Paria. Meanwhile Blanco, eluding the vigilance of the party sent against him, placed himself in communication with the Peruvian forces, and with a party of them proceeded to Chuquisaca, where he seized General Sucre, hurried him by forced marches to the head-quarters of Gamarra, and during the whole journey treated him with the greatest inhumanity and indignity.

A treaty of peace was now entered into between Generals Gamarra and Urdininea at Piquisa (6th July), by which the independence of Bolivia was guaranteed, and the object of the Peruvian invasion accomplished by the retirement of General Sucre, and the removal of the remaining Colombian troops from the territory of the republic. Accordingly the latter embarked at Arica for Colombia on the 28th of July, under the command of Colonel Brown. Sucre was then set at liberty, and formally resigned the presidency of Bolivia on the 18th of August 1828; on which occasion General Santa Cruz was elected as his successor.

General Sucre descended from his high station in a manner which accorded well with his elevated character. His message to the congress of Bolivia, dated the 4th of August, will serve as a lasting monument of his merits in organizing Bolivia, and of his impartiality in pointing out that part of the Bolivian code which he considered as most imperfect. During the two years of his administration, colleges and Lancasterian schools were established in the capitals of each of the departments, and schools of the same description for females were instituted in three of them; besides which, other schools were multiplied throughout the country under improved regulations, and

Bolivia. well provided with funds. Important ecclesiastical reforms were effected, and the number of friars so diminished that only six convents remained of the thirty-six in existence when he came into office, the funds of those suppressed having been devoted to the purposes of education and various useful public institutions. Some progress was also made in the improvement of the police, prisons, &c.; and the army was left in a very efficient state. Agriculture had been improved in all its branches, and no forced loan or contribution of any kind was made. Mining had increased so much, that during the preceding year one-third more of the precious metals had been extracted than in any former year. Commerce had also been promoted, and efforts were made to establish the free port of Cobija or La Mar. Although the amount of the revenue received had diminished in consequence of the changes in the imposts, yet such had been the economy observed by the administration, that the revenue was not only sufficient to defray all necessary expenses, but a surplus had been accumulated to meet extraordinary charges.

Santa Cruz was now elected president of the republic; General Velasco vice-president. The new governor, who happened to be absent in Chili, found, to his surprise, on reaching Chuquisaca, that General Blanco had in the mean time usurped his functions, and appointed a new vice-president. The usurper, however, did not live long to enjoy his honours; for in a week he was assassinated, and his death left Santa Cruz in undisputed possession of the chief power. From this date till the year 1834, the president directed all his efforts to developing the internal resources of the state. The better to gain his end, and attract to his own country a share of the foreign commerce which had hitherto been almost monopolized by the neighbouring states of Chili and Peru, he formed the bold design of uniting Bolivia and Peru into a confederation. The latter country was at this time in a state of anarchy. At the invitation of Orgebozo, the deposed president, Santa Cruz marched an army into Peru, gained two battles, and reinstated Orgebozo, with whose assistance he carried out his scheme, and was appointed protector of the Peru-Bolivian confederation. The two countries had just begun to prosper under his rule, when the Chilians, jealous of their commercial interests, sent an invading army, which defeated Santa Cruz at Yungay in 1839, dissolved the confederation, and compelled the protector to abdicate. He now became an exile from his country, where his influence was still dangerously great; and though he more than once tried to return, he was always intercepted. In 1843 he fell into the hands of the Peruvians, by whom he was delivered up to the Chilian government, which detained him for some time as a prisoner at Chilöe. It was at last found convenient to despatch him to Europe as Bolivian plenipotentiary; and he was till 1852 the accredited minister of that country at the courts of London, Paris, Madrid, Rome, and Brussels. After the battle of Yungay, another revolution occurred in Bolivia, which left Velasco president, and Ballivian vice-president. As the former soon showed himself incapable, the army mutinied in 1841, and endeavoured to reinstate Santa Cruz. To prevent this, the Peruvians interfered, and invaded Bolivia with a large army. The vice-president hurried to meet the invaders, routed them completely at Ingavi, in his turn entered Peru, and established himself at Arica on the Pacific. Intestine troubles, however, compelled him soon after to return home, where in 1843 he was duly elected president of the republic. Despite the numerous attempts to dispossess him of his power, he retained it till 1848, when a new revolution more formidable than its predecessors compelled him to abdicate. No regular president was appointed for two years; but the administration was carried on by Manuel Isidoro Belzu, commander-in-chief of the army. These two years are signalized by the number of revolts and conspiracies, and by the bloody atrocities of a civil war scarcely yet put down. Belzu, in spite of his extreme unpopularity, has contrived to maintain himself in power. His life has been often attempted, and more than once he has been severely wounded by the pistol-shot of the assassin. The policy of the present government of Bolivia is, unfortunately, ill adapted to repress these outrages, and is itself characterized by that narrow and jealous spirit of distrust so injurious to the prosperity of young states. A decree of 1850, for example, deprives all foreigners of the right to trade with the interior of the country, and leaves them only the inaccessible port of Cobija. In 1853, however, this act, so injurious to the prosperity of Bolivia, was rescinded; and not only was free trade proclaimed, but a large reward offered to the first steamer of any nation that should sail up to the Bolivian territory through the rivers La Plata or Amazon. Bolivia.

The year 1852, to the astonishment of all, elapsed without a revolution, or even a new civil war. It was signalized by no event of public interest, except the retirement of Santa Cruz, the death of the ex-president Ballivian, and the enactment of certain measures for the prevention of treacherous designs against the government. By these every soldier who is tempted to revolt, and gives instant information against the conspirators, is rewarded with two grades of promotion if an officer, and 6000 piastres if a private. All who are tampered with, and do not inform, are subject to the same penalties as the rebels. At the beginning of 1853, another rupture broke out between this country and Peru. The principal cause of this event was asserted to be the Bolivian coinage. Since 1830 the money struck at the national mint was stated to be only 23 per cent. below the usual alloy; the Peruvians, into whose country this coinage readily found its way, maintained that it was 33, and even 40 per cent. below the legal value. The bad feeling engendered on both sides by the mutual complaints and recriminations on this subject, was further complicated by another untoward event. The Bolivian government accused M. Paredes, the Peruvian chargé d'affaires at La Paz, of communicating false intelligence to the authorities at home, and spreading alarming rumours about the intentions of the state, and demanded his recal. The Peruvians refused to comply with the demand, but to obviate difficulties M. Paredes voluntarily retired. Pending negotiations, he was seized and expelled the country by the police. His countrymen demanded reparation for this outrage, which was refused. Then began a mutual system of reprisals; the result of which was a declaration of war, and the occupation of Cobija by a Peruvian fleet. The matter here rests for the present (Jan. 1854), as the war has not yet been prosecuted to extremes by either party.

In 1836, slavery was formally abolished in Bolivia by act of congress, though the native Indians are still considered as in a state of tutelage, and continue to pay the capitation tax; and in 1839 the entire political constitution of Bolivia was remodelled. In 1843 it was again altered; and was not finally established till 1848. The executive is now vested in a president, who holds office for four years, and is re-eligible after an interval of the same duration. He is assisted by a council of state and four ministers. The power of legislation belongs to the congress, which consists of a senate and a chamber of deputies. The congress, whose sessions last for two months, meets annually on the 6th of August. Every department returns three senators; while the deputies are elected in the proportion of 1 to 40,000 electors. Every elector must be able to read and write, and possess a capital of 4000 piastres, or an equivalent.

Justice is administered gratuitously. There is a justice of peace for each canton; a *juez de letras* at the headquarters of the province; a court of appeal in the capital of each department; while the supreme court sits at Chuquisaca,

Boll || Bollards.

and is composed of four judges and a president. By the decree of 1845, a system of public instruction was organized and promulgated. A university was founded, colleges were established, and elementary schools opened in some places. Teachers and professors, however, were not to be found in Bolivia; and the inducements held out by the government were insufficient to attract men of learning and skill from other countries. The funds, moreover, which were originally set apart by Bolivar for this most important object, have been gradually diverted by succeeding governments, so that now the *beneficencia* is in arrears in almost all the departments. That of Cochabamba has lost since 1844, 300,000 piastres, while those of Oruro, Potosi, and Chuquisaca, are unable to defray current expenses.

The present military force of Bolivia consists of three battalions of infantry, and two regiments of cavalry. Though the sum total of the standing army amounts only to 1500 men, yet the exigencies of the country render every man more or less familiar with the use of arms.

The finances of Bolivia have, of late years, been much impaired by the general insecurity that pervaded every department of public affairs. During the civil wars, according to the report of the minister of finance in 1850, the mint, the bank, and the public treasury, were literally swept of their funds. In 1849 the deficit amounted to 473,752 piastres, in 1849 it rose to 506,516 piastres. In 1850 there was a surplus of 237,473 piastres. The national debt of Bolivia is entirely confined to the country itself, and consists, 1. Of the bonds of the loan contracted in 1826, chiefly to reimburse the founders of the independence; and, 2. Of the loan of 1843, which amounts to 2,181,216 piastres, bearing interest at 6 per cent. The interest of arrears since 1847 amounts to 392,618 piastres. The value of the entire commerce of Bolivia, imports and exports included, is at present about L.1,000,000 sterling.

Bologna.

The press is not without its representatives in Bolivia. The majority of the journals published there are printed at the expense of the government, which, however, does not hold itself responsible for any statements they may contain, In Chuquisaca is published *The Naked Truth*; in La Paz, *The Epoch* and *The Prism*; in Oruro *The Republican*; and in Tarija *The Telegraph*. The existence of these journals is almost the only sign of intellectual life in the Bolivian republic. (*Secret Report of D. Jorge Juan and D. Antonio de Ulloa*, by Barry; *Rélation Historique des Voyages de Humboldt et Bonpland*; Brackenridge's *Voyage to South America*; Andrews' *Travels in South America*; Temple's *Travels in South America*; *Edinburgh New Phil. Jour.* Oct. 1829 to April 1830; *Memoirs of General Miller*.[1] (J. G.)

BOLL (Saxon *bolla*, a bowl), a Scotch measure for corn, containing 4 firlots. (See FIRLOT.) The boll of wheat or beans is equivalent to 4 Winchester bushels; of oats, barley, or potatoes, to 6 bushels. A boll of meal is equal to 140 lb. avoirdupois. This measure is now abolished, corn being measured by the imperial standard measure.

BOLLANDUS, JOHN, a learned Flemish Jesuit, born at Tirlemont in Limbourg Aug. 13. 1596. He is celebrated as the first of that series of hagiographers, called after him *Bollandists*, who compiled the vast collection of the lives of Romish saints known as the *Acta Sanctorum*. Rosweide, a learned Jesuit, had published in 1607 the plan of such a work, but died in 1629 without having realized his design. Bollandus was appointed to this work, with the approval of Pope Alexander VII., by the conclave of his order, and in 1635 received as his coadjutor Godfrey Henschen. Discarding Rosweide's plan of reproducing unchanged the whole of the ancient legends, he set himself to the task of verifying their contents by an examination of all the historical sources at his command. Of this immense work he lived to complete only five volumes. After his death in 1665, the series was continued by Henschen, Papebroch, Baert, Janning, and a host of other writers. On the abolition of the Jesuit order in 1763, the work was for a time interrupted. It was resumed in 1779, and again interrupted in 1792 by the French invasion. At this time the series extended to 54 vols. folio. The order pursued in the work was to give under the names of each month the lives of the saints whose days occur in that month. The number of biographies is estimated at 25,000. The 54 vols. brought down the series to the 16th of October. A continuation of this work is now in progress, under the auspices of the Belgian government. Two additional volumes have already appeared. This vast collection, with much that is useless and legendary, contains a valuable mine of facts in civil and ecclesiastical history.

BOLLARDS, large posts set into the ground on each side of a dock. On docking or undocking ships, large blocks are lashed to them; and through these blocks are reeved the transporting hawsers to be brought to the capstans.

BOLOGNA, one of the legations or provinces of the Papal States, bounded on the north by Ferrara, east by Ravenna, south by Tuscany, and west by Modena. Area 1430 square miles; pop. 350,600. It is a district of great natural fertility, and though but indifferently cultivated produces abundant crops of rice, barley, wheat, and pulse, besides hemp, flax, silk, oil, wine, figs, almonds, chestnuts, and other fruits.

BOLOGNA, the principal city of the above legation, and the see of an archbishop, is situated between the rivers Reno and Savena, in a beautiful and fertile plain at the foot of the lower slopes of the Apennines, 399 feet above the level of the Adriatic, and 23 miles S.E. of Modena. Lat. 44. 30. N. Long. 11. 21. E. The city is about 2 miles in length by 1½ in breadth, and is surrounded by a high brick wall, having 12 gates, but without fortifications. It is intersected by the Reno canal, and is divided into four quarters. The streets are clean and well paved, but generally narrow and crooked; the houses are mostly three stories high, with deep projecting roofs, and are generally surrounded with arcades. The *Piazza Maggiore*, or principal square, has many fine edifices. In the centre is a fountain, adorned with a colossal statue of Neptune, by Giovanni de Bologna, and said to be one of the finest modern statues in Italy. Among its principal buildings are the *Palazzo Pubblico*, the *Palazzo del Podesta*, and numerous private palaces; the two leaning towers of Asinelli and Garisenda, the *Scuole Pie*, cathedral, &c. The university, the oldest and at one time the most celebrated in Italy, has lost its reputation, and is not now frequented by above 600 or 700 students. The library contains about 140,000 volumes and 9000 MSS. The famous linguist Cardinal Mezzofanti was for some time librarian here. The *Accademia delle Belle Arte* has a rich gallery of paintings, chiefly by native artists. There are cabinets of mineralogy and natural history; academies of science, music, sculpture, &c.; several schools; a public library; 74 churches, 35 convents for monks, and 38 for nuns; 9 hospitals, a *monte di pietà*, and many other benevolent institutions. Its principal manufactures are crape, silk, glass, chemicals, wax can-

[1] The principal facts connected with the later history of Bolivia were obtained from some valuable manuscripts and public documents with which the writer (the late Dr Gillies) was favoured by the author of the *Memoirs of General Miller*. More recent sources have furnished the supplementary portion of this article.

Bologna ‖ Bolscheretsk.

dles, musical instruments, paper, the celebrated *Mortadelle* sausages, &c. Pop. (1844) 75,000.

Bologna is said to have been founded by Felsina, an Etruscan king, who gave it his name and made it the capital of the twelve Etruscan cities. When, in the time of Tarquinius Priscus, it was occupied by a tribe of the Boii, its name was changed to Bononia, although some contend that this name was given to it by an Etruscan king Bonor. Under the Romans Bononia gradually became a place of some consequence, and it was chosen in the time of the second triumvirate as the seat of an interview between Octavius, Antony, and Lepidus. After the fall of the Roman empire it passed into the power of the Lombards, and on their subjugation by Charlemagne it was united to the empire of the Franks. In 962 it threw off the yoke and became a republic, at first aristocratic, but towards the end of the thirteenth century democratic. The middle ages formed the period of its greatest celebrity and importance. In the contest between the Guelfs and the Ghibellines, the Bolognese, after a long neutrality, sided with the former, and became deeply involved in struggles both foreign and intestine. After innumerable revolutions of fortune, Bologna was finally annexed to the papal dominions by Pope Julian II. in 1506. After its capture by the French in 1796, it was made a constituent part of a new republic, and afterwards of the kingdom of Italy. On the fall of Napoleon it reverted to the papal dominion. A revolution in 1831 was quelled by the intervention of Austrian troops. In 1848 the Austrian general Welden made an attack upon this city, but was repulsed with great bravery by the inhabitants. The following year, however, the Bolognese were obliged to surrender after a heroic defence of ten days. The Austrians have since then maintained possession, which has subsequently been sanctioned by a treaty with the papal government.

Bologna, *Giovanni di*, (or Giovanni Bologna, as he styled himself), a very celebrated sculptor, born at Douay in 1524. He went early to Italy, and studied at Florence, where his finest works still remain. His two most celebrated productions are the single bronze figure of Mercury, poised on one foot, resting on the head of a Zephyr, as if in the act of springing into the air (in the Florentine gallery); and the famous marble group of the Rape of the Sabines, which received this name, as we read in Lanzi, after it was finished. It is now in the Loggia de Lanzi of the ducal piazza. Giovanni was also employed at Genoa, where he executed various excellent works, chiefly in bronze. All his pieces are characterized by great spirit and elegance.

The surname of Bologna is common to a large number of Italian artists and literary men, from the twelfth to the seventeenth century.

BOLOGNESE School, sometimes called the Lombard School of painting, was founded by the Caracci. Among the principal painters it produced were Domenichino, Lanfranco, Coreggio, Guido, Schidone, Caravaggio, Zampieri, Primaticcio, &c.

BOLOGNIAN Stone, a radiated sulphate of barytes, found in roundish masses, composed of radiating fibres. When calcined, pulverized, converted into a paste with mucilage, and then dried in pieces about a quarter of an inch thick, it affords a pyrophorus, which, after a few minutes' exposure to the sun's rays, gives light enough in the dark to render the figures on the dial-plate of a watch visible. It was first discovered at Monte Paterno near Bologna, whence it derives its name.

BOLSCHAIA Reka, or the Great River, a river of Kamtschatka, which rises in a lake about 120 miles from its mouth. It flows into the sea of Okhotsk, in Lat. 54. 52. N. It is navigable from its source to its mouth, on the south side of which there is a lighthouse.

BOLSCHERETSK, a town and fortress of Kamtschatka, formerly the capital of that peninsula, and the seat of the government. It is situated on the river Bolschaia Reka, twenty miles from its mouth, in an extensive plain stretching along the sea-shore. Present pop. scarcely 200. Long. 157. E. Lat. 53. N.

Bolsena ‖ Bolton-le-Moors.

BOLSENA (ancient *Volsinium* or *Vulsinium*), a town of the Papal States, in the delegation of Viterbo, and ten miles S. by E. of Orvieto. It is situated on the north shore of the lake of the same name (*Lago di Bolsena*); but is chiefly remarkable for the remains of the ancient city in its vicinity, among which are numerous granite columns, supposed to have formed part of the temple of the Etruscan goddess Norcia. This was one of the most ancient and powerful of the Etruscan cities. After a series of struggles with the Romans, the Volsinians were finally subdued, their city razed to the ground, and themselves obliged to settle in a less defensible site in the plain. The new city was the birthplace of Sejanus, the favourite of Tiberius. It is now a miserable village of 1700 inhabitants.

The lake of Bolsena is about ten miles in length by eight in breadth, and surrounded by well-wooded hills. It contains two small islands, and discharges its waters by means of the Marta into the Mediterranean. The surrounding country is extremely unhealthy.

BOLSOVER, a small town in Derbyshire, best known for its limestone quarries, which have supplied the yellow stone for the new houses of parliament. Pop. of parish in 1851, 1611.

BOLSWERT, Boetius-Adam, an eminent engraver, born at Bolswert in Friesland, about the year 1580: died in 1634. It is inferred, from his style, that he studied in the school of Blömaert. His principal works are the following:—after Rubens, "The Last Supper," "Resurrection of Lazarus," "The Crucifixion," and "The Judgment of Solomon;" "The Martyrdom of St Stephen," after Coningloo; "Jesus with Martha and Mary," after Goiomar; after Blömaert, "The Adoration of the Shepherds," "The Holy Women in the Desert," in twenty plates, four landscapes, and twenty landscapes inscribed *O nimium felix*, 1616. Bolswert was also the author of a romance entitled *The Pilgrimage to Jerusalem.*

Bolswert, or Bolwert, Schieltius, the younger brother of the preceding, lived at Antwerp about the middle of the seventeenth century, and has left admirable prints after some of the finest works of Rubens and Vandyck. He worked entirely with the burin, and without stippling. His finest works are—the "Christ crowned with Thorns," after Vandyck; "The Assumption," "The Brazen Serpent," "Mercury and Argus," and two prints of Satyrs, after Jordaens; "A Lion Hunt," after Rubens; and a "Crucifixion."

BOLT-Rope, a rope sewed round the edges of a sail, to strengthen it.

BOLTER, or Boulter, a kind of sieve, made of woollen, hair, or wire, for separating bran from flour, &c.

BOLTING Mill, an engine for sifting with more expedition. The cloth around it is called the *bolter.*

BOLTON, or Boulton, Edmund, an ingenious English antiquarian of the seventeenth century. His principal work is that entitled *Nero Cæsar, or Monarchie Depraved*, dedicated to his patron the Duke of Buckingham, lord high admiral, printed at London 1624, folio, and adorned with several curious and valuable medals. It contains also an interesting account of the British revolt under Boadicea. He also wrote, 1. An English translation of Lucius Florus's Roman History; 2. *Hypercritica*, or a rule of judgment for reading or writing our histories; 3. The Elements of Armories; and some other works. The time of his death is unknown.

Bolton le Moors, a municipal and parliamentary borough of England, in the hundred of Salford, Lancashire, 12 miles N.W. of Manchester. The small stream Croal,

Bomb. which falls into the Jewell, divides it into Great and Little Bolton; the former being on the south side of that stream. This town has latterly been much improved by the formation of wide and well-paved streets and squares, but it has still several narrow and crooked streets and lanes. In the vicinity are some handsome villas, particularly on the south side of the town. Bolton is well supplied with water, a company having been formed for that purpose in 1824. It is brought from springs about four miles N.E. of the town. The corporation has lately purchased the water-works from the company. Bolton has an ancient parish church, six other churches, and a chapel of ease, two Roman Catholic chapels, three Independent, six Methodist, and nine other dissenting chapels; a free grammar-school, two charity schools, and numerous others. Among its public buildings are the town-hall, cloth-hall, public baths, exchange, theatre, barracks, &c. It has also a mechanics' institute, savings-bank, several libraries and reading-rooms, and numerous charities. The woollen manufacture was introduced here by the Flemings in the fourteenth century, but it is only since the introduction of spinning machinery that Bolton has become one of the principal seats of the cotton manufacture in England. In 1849 there were 53 cotton mills within the borough, giving employment to 9759 persons. It has also a number of large foundries and iron works, bleach works, a paper mill, &c. There are numerous coal mines in the vicinity. Bolton is connected by canal as well as by railway with Manchester and Bury; and by railway with Liverpool, Preston, Leigh, and Blackburn. Since the Reform Act it returns two members to parliament. Population (1851) 61,171. Arkwright and Crompton, inventors of the spinning-frame and mule-jenny, were both natives of the parish.

BOMB (*βόμβος*, a loud noise), in military affairs, a large shell of cast-iron, with a vent to receive a fusee, which is made of wood. The shell being filled with gunpowder, the fusee is driven into the vent within an inch of the head, and fastened with a cement made of quicklime, ashes, brick-dust, and steel-filings, worked together in a glutinous water; or of four parts of pitch, two of colophony, one of turpentine, and one of wax. This tube is filled with a combustible matter made of two ounces of nitre, one of sulphur, and three of gunpowder-dust, well rammed. To preserve the fusee, it is pitched over, but uncased when the bomb is put into the mortar, and covered with gunpowder-dust, which, taking fire by the flash of the powder in the chamber of the mortar, burns all the time the bomb is in the air; and when the composition in the fusee is spent, it fires the powder in the bomb, which bursts with great violence and commits dreadful devastation. Bombax.

Bombs may be used without mortars, as was done by the Venetians at Candia, when the Turks had possessed themselves of the ditch. Bombs were rolled down upon them along a plank with ledges set sloping towards their works. Bombs did not come into common use before the year 1634, and then only in the Dutch and Spanish armies. One Malthus, an English engineer, is said to have first carried them into France, where they were used at the siege of Collioure. The art of throwing bombs or shells constitutes a branch of gunnery. See GUNNERY.

BOMB-*Vessel*, or *Bomb-Ketch*, a small ship of unusual strength, employed for throwing bombs into a fortress; said to have been invented by M. Reyneau, and first used at the bombardment of Algiers. Till then it had been judged impracticable to bombard a place from the sea.

BOMBARDIER, a gunner whose business is to drive the fusee, fix the shell, and load and fire the mortar.

BOMBARDO, a musical instrument of the wind kind, similar to the bassoon, and used as a bass to the hautboy.

BOMBASINE (*bombycinus*, from *bombyx*, a silkworm), a name given to two sorts of stuffs, the one of silk, the other crossed of cotton.

BOMBAST, in composition, is a serious endeavour, by strained description, to elevate a low or familiar subject; which, instead of being sublime, never fails to be ridiculous. The mind, in some animating passions, is indeed apt to magnify its objects beyond natural bounds; but such hyperbolical description has its limits, and when carried beyond these it degenerates into burlesque. An ambitious writer who has not natural elevation of genius is extremely apt to glide unconsciously into bombast. He strains above his pitch, and the violence of the effort generally carries him beyond the limits of propriety.

BOMBAX, a genus of soft, spongy trees, of the natural order of Bombaceæ. The most noted is *B. Ceiba*, the silk-cotton tree of South America, the trunk of which is often 100 feet high, and of enormous thickness, so that a canoe hollowed out of its spongy stem will carry at once fifteen or twenty hogsheads of sugar. *B. pubescens* of Brazil attains only a height of 20 or 30 feet. Its tough bark is manufactured into ropes.
